

Method for Making Photofunctional Contact Lenses

This invention is related to a method for producing contact lenses, in particular, silicone hydrogel contact lenses, having a central optical zone that possesses at least one photo functionality. This invention also provides contact lenses made according to a method of the invention.

BACKGROUND

Conventionally, UV-absorbing compounds have been incorporated into contact lenses to make UV-absorbing contact lenses to protect eyes from UV-radiations. Recently, there have been proposed various photochromic contact lenses for protecting eyes from UV-radiations (see, e.g., U.S. Pat. Nos. 4681412, 6017121, 6174464, 6224945, 7261844, 7368072, 7556750, 7560056, 7584630, 7641337, 7999989, 8158037, 8697770, 8741188, 9052438, 9097916, 9377569, 9465234, 9904074, 10197707). Those proposed photochromic contact lenses contains photochromic compounds which are capable of undergoing a reversible color change, e.g., from "clear" to blue or other color, upon exposure to UV/HEVL radiation.

Typically, photochromic contact lenses can be obtained by adding a photochromic compound in a polymerizable composition (i.e., lens formulation) for forming the contact lenses and then by curing the polymerizable composition in contact lens molds according to a cast-molding lens manufacturing process. A conventional cast-molding lens manufacturing process comprises: one single-step curing (polymerizing) of one single polymerizable composition (lens formulation) within disposable plastic molds typically consisting of two single-use mold halves; opening molds; optionally but preferably delensing (i.e., removing cast-molded lenses from the molds); and being subjected to various post-molding processes including extraction, hydration, packaging, and sterilization, etc.

However, photochromic contact lenses obtained according to such a conventional cast-molding process have photochromic compound incorporated uniformly within the polymer matrix of the photochromic contact lenses and are, from edge-to-edge, capable of undergoing a reversible color change upon exposure to UV/HEVL-radiation. Such photochromic contact lenses are not desirable for cosmetic reasons. It would be desirable to produce a photochromic contact lens that changes color only in the central pupil region.

U.S. Pat. Nos. 7368072, 7560056, 8697770 and 9904074 disclose methods for making photochromic contact lenses only the central pupillary regions of which can undergo a reversible color change upon exposure to UV/HEVL-radiation. Those methods comprise steps of: dosing a photochromic lens-forming composition onto the central region of the molding surface of a mold half and followed by adding a clear lens-forming composition on the top of the photochromic lens-forming composition, wherein the photochromic lens-

forming composition has a viscosity much higher than the clear lens-forming composition; mating with the other mold half to form a cavity with the photochromic and clear lens-forming compositions therewithin; and curing the photochromic and clear lens-forming compositions within the cavity of the mold to form the photochromic contact lens. However, handling and dosing of a high viscous photochromic lens-forming composition could be challenging in a production environment.

Therefore, there is still a need for a method for making hydrogel contact lenses only the central pupillary regions of which possesses at least one photo functionality.

No. 6719929, the incorporation of wetting agents into a lens formulation for making contact lenses proposed in U.S. Pat. Nos. 6367929 and 6822016, reinforced mold-transfer coating disclosed in U.S. Pat. No. 7858000, and a hydrophilic coating composed of covalent attachment or physical deposition of one or more layers of one or more hydrophilic polymer onto the surface of a contact lens disclosed in US Pat. An "average contact angle" refers to a water contact angle (static water contact angle measured by Sessile Drop), which is obtained by averaging measurements of at least 3 individual contact lenses.

The term "central axis" in reference to a contact lens means a line passing through the geometrical centers of the anterior and posterior surfaces of the contact lens.

In general, the invention is directed to a method for making contact lenses, in particular, SiHy contact lenses, each of which comprises a central zone that has a diameter of about 13 mm or less, is concentric with the central axis of the contact lens, and possesses at least one photochemical functionality.

Figure 1 schematically illustrates a contact lens of the invention. The contact lens **100** has an anterior surface **102**, an opposite posterior surface, a central axis **101**, and a central zone **110** that has a diameter **120**, is concentric with the central axis **101** of the contact lens **100**. The central zone **110** comprises at least one photochemically functional compound that is distributed in its front portion **112** (a portion near and including a central

portion of the anterior surface) and provides at least one photochemical functionality to the central zone.

The invention is partly based on the discovery that such contact lenses can be produced according to a process involving: a first step of dosing – applying a small amount of a first polymerizable fluid composition containing at least one photochemically functional compound on a central portion of the molding surface of a female mold half to form a circular layer of the first polymerizable fluid composition; a 1st step of curing – partially curing, *in situ*, the circular layer of the polymerizable fluid composition in the female mold half; a 2nd step of dosing – introducing an amount of a second polymerizable fluid composition over the partially-cured circular layer on the molding surface of the female mold half; and a 2nd step of curing – curing the second polymerizable fluid composition and the partially-cured circular layer immersed therein in the mold cavity formed between the the molding surfaces of the female mold half and a male mold half. The second polymerizable fluid composition are substantially identical to the first polymerizable fluid composition except that the second polymerizable fluid composition is free of said at least one photochemically functional compound present in the first polymerizable fluid composition.

It is found that the partial curing of the first polymerizable fluid composition can be achieved by controlling the amount of actinic irradiation exposed on the circular layer in the female mold half (e.g., through controlling the exposure time of the the actinic irradiation). After the partial curing, the polymerizable components in the partially-cured circular layer of the first polymerizable fluid composition will not be able to diffuse into and to blend with the second polymerizable fluid composition. But, the second polymerizable fluid composition may still be able to diffuse, at least partially, into the partially-cured circular layer in the molding assembly. Then, the subsequent curing step will produce contact lenses, each of which comprises a central zone that has a diameter of about 13 mm or less, is concentric with the central axis of the unprocessed contact lens, and possesses at least one photochemical functionality.

A method of the invention can offer the following advantages. First, the entire contact lens is fabricated with same material. This approach can avoid issues of lens physical integrity which is oftent encounter when a lens is composed with two different materials. It can also avoid issue of delamination or lens distortion because there is no or minimized changes in lens swelling in different parts of a contact lens. Further, the photochemical functionalities is limited in the optical zone of a contact lens, i.e., over the pupil area of an eye when being worn. Any color associated with the photochemical functionality would have minimized adverse impacts upon the perception for an end user and his/her surrounding people.

A photochromic vinylic monomer can be obtained by reacting a reactive (meth)acrylamido or (meth)acryloxy monomer having a first reactive functional group ($-\text{COCl}$, $-\text{COBr}$, $-\text{COOH}$, $-\text{NHR}_{\text{N}_2}$, $-\text{NCO}$, $-\text{OH}$, $-\text{CHO}$, , , or $-\text{N} \langle \text{vinylidene} \rangle \text{R}_0$ in which R_0 is hydrogen or methyl and R_{N_2} is hydrogen, a linear or branched $\text{C}_1\text{-C}_{15}$ alkyl, cyclohexyl, cyclopentyl, a substituted or unsubstituted phenyl, or a substituted- or unsubstituted-phenyl- $\text{C}_1\text{-C}_6$ alkyl) with a reactive photochromic compound having a second reactive functional group ($-\text{COOH}$, $-\text{NHR}_{\text{N}_2}$, , , , $-\text{NCO}$, $-\text{OH}$, $-\text{SH}$, $-\text{CHO}$, , , or $-\text{N} \langle \text{vinylidene} \rangle \text{R}_0$, in the absence or presence of a coupling agent (i.e., having two of the reactive functional groups listed above) under well known coupling reaction conditions, to form a photochromic compound.

Lens molds for making contact lenses including hydrogel contact lenses are well known to a person skilled in the art and, for example, are employed in cast molding or spin casting. For example, a mold (for cast molding) generally comprises at least two mold sections (or portions) or mold halves, i.e. first and second mold halves. The first mold half defines a first molding (or optical) surface and the second mold half defines a second molding (or optical) surface. The first and second mold halves are configured to receive each other such that a lens-forming cavity is formed between the first molding surface and the second molding surface. The molding surface of a mold half is the cavity-forming surface of

the mold and in direct contact with the polymerizable composition.

Methods of manufacturing mold sections for cast molding a contact lens are generally well known to those of ordinary skill in the art. The process of the present invention is not limited to any particular method of forming a mold. In fact, any method of forming a mold can be used in the present invention.

In general, a mold comprises at least two mold halves (or mold sections), one male half and one female mold half. The male mold half has a first molding (or optical) surface which is in direct contact with a polymerizable composition for cast molding of a contact lens and defines the posterior (concave) surface of a molded contact lens; and the female mold half has a second molding (or optical) surface which is in direct contact with the polymerizable composition and defines the anterior (convex) surface of the molded contact lens. The male and female mold halves are configured to receive each other such that a lens-forming cavity is formed between the first molding surface and the second molding surface.

The mold halves can be formed through various techniques, such as injection molding. Methods of manufacturing mold halves for cast-molding a contact lens are generally well known to those of ordinary skill in the art. The process of the present invention is not limited to any particular method of forming a mold. In fact, any method of forming a mold can be used in the present invention. The first and second mold halves can be formed through various techniques, such as injection molding or lathing. Examples of suitable processes for forming the mold halves are disclosed in U.S. Pat. Nos. 4444711; 4460534; 5843346; and 5894002.

Virtually all materials known in the art for making molds can be used to make molds for making contact lenses. For example, polymeric materials, such as polyethylene, polypropylene, polystyrene, PMMA, Topas® COC grade 8007-S10 (clear amorphous copolymer of ethylene and norbornene, from Ticona GmbH of Frankfurt, Germany and Summit, New Jersey), or the like can be used. Other materials that allow UV light transmission could be used, such as quartz glass and sapphire.

In accordance with the invention, the first or second polymerizable fluid composition can be dispensed onto the molding surface of a female mold half according to any known techniques.

A specific amount of a first polymerizable fluid composition is typically dispensed into a female mold half by means of a dispensing device and then a male mold half is put on and the mold is closed. As the mold closes, any excess first polymerizable fluid composition is pressed into an overflow provided on the female mold half (or alternatively on the male mold half).

The molding assembly (i.e., the closed mold containing the first polymerizable fluid

composition and the partially-crosslinked circular layer immersed therein) is subsequently irradiated with a UV or visible light (i.e., cured or polymerized), as known to a person skilled in the art, to produce a molded unprocessed hydrogel contact lens.

Where the first or second polymerizable fluid composition comprises at least one member selected from the group consisting of a UV-absorbing vinylic monomer, a polymerizable UV/HEVL-absorbing compound, a photochromic compound, a fluorescent compound, the free radical initiator is preferably a visible light photoinitiator (e.g., a benzoylphosphine initiator and/or an acylgermanium photoinitiator) and crosslinking is initiated upon exposure to a visible light in a region between 420 nm to 500 nm to crosslink the polymerizable components in the first polymerizable fluid composition to form molded unprocess contact lenses. Light source can be any ones emitting light in the 420-500 nm range sufficient to activate acylgermanium photoinitiators. Blue-light sources are commercially available and include: the Palatray CU blue-light unit (available from Heraeus Kulzer, Inc., Irvine, Calif.), the Fusion F450 blue light system (available from TEAMCO, Richardson, Tex.), Dymax Blue Wave 200, LED light sources from Opsytec (435 nm, 445 nm, 460 nm), and the GE 24" blue fluorescent lamp (available from General Electric Company, U.S.). A preferred blue-light source is the LED from Opsytec (those described above).

After curing, the molds can be opened according to any techniques known to a person skilled in the art. After the mold is separated, the molded unprocessed hydrogel contact lens adheres to one of the male and female mold halves.

The unprocessed hydrogel contact lens adhered on the lens-adhered mold half can be removed from the lens-adhered mold half and then subject to one or more post molding processes.

For example, unprocessed hydrogel contact lens can be extracted with a liquid extraction liquid medium to remove unpolymerized polymerizable components and formed and oligomers. In accordance with the invention, the extraction liquid medium is any solvent capable of dissolving the organic solvent, unpolymerized polymerizable materials, and oligomers in the dry contact lens. Water, any organic solvents known to a person skilled in the art, or a mixture thereof can be used in the invention. Preferably, the organic solvents used extraction liquid medium are water, a buffered saline, a C₁-C₃ alkyl alcohol, 1,2-propylene glycol, a polyethyleneglycol having a number average molecular weight of about 400 Daltons or less, a C₁-C₆ alkylalcohol, or combinations thereof.

The hydrogel contact lenses can also be subjected to further processes, such as, for example, surface treatment (for example, such as, plasma treatment, chemical treatments, the grafting of hydrophilic monomers or macromers onto the surface of a lens, Layer-by-layer coating, in-package crosslinking of a thermally-reactive hydrophilic polymeric material,

etc.); packaging in lens packages with a packaging solution which can contain about 0.005% to about 5% by weight of a wetting agent (e.g., a hydrophilic polymer), a viscosity-enhancing agent (e.g., methyl cellulose (MC), ethyl cellulose, hydroxymethylcellulose, hydroxyethyl cellulose (HEC), hydroxypropylcellulose (HPC), hydroxypropylmethyl cellulose (HPMC), or a mixture thereof), or an in-package-coating material; sterilization such as autoclave at from 118 to 124°C for at least about 30 minutes; and the like.

Preferred surfaces treatments are LbL coating such as those described in U.S. Pat. Nos. 6451871, 6719929, 6793973, 6811805, and 6896926, plasma treatment, in-package-coating such as those disclosed in U.S. Pat. Nos. 8557334, 8529057 and 9505184. A preferred plasma treatment is those processes in which an ionized gas is applied to the surface of an article as described in U.S. Pat. Nos. 4312575 and 4632844.

The hydrogel contact lens is hydrated in water or an aqueous solution to replace the liquid extraction medium, according to any method known to a person skilled in the art.

The hydrated and/or surface-treated photochromic contact lens can further subject to further processes, such as, for example, packaging in lens packages with a packaging solution which is well known to a person skilled in the art; sterilization such as autoclave at from 118 to 124°C for at least about 30 minutes; and the like.

Lens packages (or containers) are well known to a person skilled in the art for autoclaving and storing a soft contact lens. Any lens packages can be used in the invention. Preferably, a lens package is a blister package which comprises a base and a cover, wherein the cover is detachably sealed to the base, wherein the base includes a cavity for receiving a sterile packaging solution and the contact lens.

Lenses are packaged in individual packages, sealed, and sterilized (e.g., by autoclave at about 120°C or higher for at least 30 minutes under pressure) prior to dispensing to users. A person skilled in the art will understand well how to seal and sterilize lens packages.

A SiHy contact lens of the invention has an oxygen permeability of preferably at least about 40 barrers, more preferably at least about 60 barrers, even more preferably at least about 80 barrers (at about 35°C).

A hydrogel contact lens of the invention has an elastic modulus of about 1.5 MPa or less, preferably about 1.2 MPa or less, more preferably from about 0.3 MPa to about 1.0 MPa (at a temperature of from about 22°C to 28°C).

A hydrogel contact lens of the invention further has an equilibrium water content of from about 15% to about 75%, more preferably from about 20% to about 70% by weight, even more preferably from about 25% to about 65% by weight (at room temperature) when fully hydrated. The equilibrium water content of a photochromic contact lens can be measured according to the procedure disclosed in Example 1.

In a further aspect, the invention provides a hydrogel contact lens obtained by the method of the invention.

The previous disclosure will enable one having ordinary skill in the art to practice the invention. Various modifications, variations, and combinations can be made to the various embodiment described herein. In order to better enable the reader to understand specific embodiments and the advantages thereof, reference to the following examples is suggested. It is intended that the specification and examples be considered as exemplary.

Example 1

Oxygen Permeability Measurements

Unless specified, the oxygen transmissibility (Dk/t), the intrinsic (or edge-corrected) oxygen permeability (Dk_i or Dk_e) of a lens and a lens material are determined according to procedures described in ISO 18369-4.

Equilibrium Water Content

The equilibrium water content (EWC) of contact lenses are determined as follows.

Amount of water (expressed as percent by weight) present in a hydrated hydrogel contact lens, which is fully equilibrated in saline solution, is determined at room temperature. Quickly stack the lenses, and transfer the lens stack to the aluminum pan on the analytical balance after blotting lens in a cloth. The number of lenses for each sample pan is typically five (5). Record the pan plus hydrated weight of the lenses. Cover the pan with aluminum foil. Place pans in a laboratory oven at 100 ± 2 °C to dry for 16-18 hours. Remove pan plus lenses from the oven and cool in a desiccator for at least 30 minutes. Remove a single pan from the desiccator, and discard the aluminum foil. Weigh the pan plus dried lens sample on an analytical balance. Repeat for all pans. The wet and dry weight of the lens samples can be calculated by subtracting the weight of the empty weigh pan.

Elastic Modulus

The elastic modulus of a contact lens is determined using a MTS insight instrument. The contact lens is first cut into a 3.12 mm wide strip using Precision Concept two stage cutter. Five thickness values are measured within 6.5mm gauge length. The strip is mounted on the instrument grips and submerged in PBS (phosphate buffered saline) with the temperature controlled at 21 ± 2 °C. Typically 5N Load cell is used for the test. Constant force and speed is applied to the sample until the sample breaks. Force and displacement data are collected by the TestWorks software. The elastic modulus value is calculated by the TestWorks software which is the slope or tangent of the stress vs. strain curve near zero elongation, in the elastic deformation region.

Transmittance

Contact lenses are manually placed into a specially fabricated sample holder or the like which can maintain the shape of the lens as it would be when placing onto eye. This holder is then submerged into a 1 cm path-length quartz cell containing phosphate buffered saline (PBS, pH $\sim$ 7.0 – 7.4) as the reference. A UV/visible spectrophotometer, such as, Varian Cary 3E UV-Visible Spectrophotometer with a LabSphere DRA-CA-302 beam splitter or the like, can be used in this measurement. Percent transmission spectra are collected at a wavelength range of 250-800 nm with %T values collected at 0.5 nm intervals. This data is transposed onto an Excel spreadsheet and used to determine if the lenses conform to Class 1 UV absorbance. Transmittance is calculated using the following equations:

$$\text{UVA \%T} = \text{Average \% Transmission between 315 nm and 380 nm} \times 100$$

$$\text{UVB \%T} = \text{Average \% Transmission between 280 nm and 315 nm} \times 100$$

$$\text{Violet \%T} = \text{Average \% Transmission between 380 nm and 440 nm} \times 100.$$

Photo-rheology: The photo-rheology experiment measures the elastic (G') and viscous modulus (G'') as a function of time during curing. The experiment is conducted by using an appropriate light source, optionally cutoff filters to select wavelengths of interest, and a rheometer. For example, a light source can be a LED that delivers a visible light having a spectral centroid of about 452 nm and a total irradiance of about 54 mW/cm² (OPSYTEC DR. GROEBEL). Alternatively, a light source can be a UV light (Hamamatsu, with 330nm cut-off filter, total irradiance of 16 mW/cm²). The sample (i.e., a polymerizable composition) is placed between a quartz plate that allows the actinic radiation (i.e., a visible light with a spectral centroid of about 452nm and a total irradiance of about 54 mW/cm²) to pass through and the rheometer. The curing time of a polymerizable composition is determined when the elastic modulus (G') reaches a plateau.

Example 2

Polymerizable Compositions

Two polymerizable compositions for forming silicone hydrogel materials are prepared by lending all the required components to have the compositions shown in Table 1.

Table 1

	Components (weight part units)				
	G-PDMS-D2	DMA	PrOH	RhoMA	DC 1173
Formulation 2A	34.62	35.26	29.63	0	0.50
Formulation 2B	35.09	34.97	29.40	0.03	0.50

Photo-rheology study

Photo-rheology data is acquired by curing Formulation 2A and 2B by using UV light (Hamamatsu, with 330nm cut-off filter, total irradiance of 16 mW/cm²). The result in Figure 2 shows that G' is 120 kPa, and curing time is 20s.

Fabrication of SiHy contact lens with a central fluorescent zone

~10mg Formulation 2B is dosed to the center of a female (FC) mold half (made of polypropylene) of a plastic mold (power: -3.0) to form a circular layer, and partially cured by UV light (Hamamatsu, with 330nm cut-off filter, total irradiance of 16 mW/cm²) for 3 seconds. It is found that this portion (a circular layer) is not able to freely flow in the open FC mold half. ~30mg Formulation 2A is added to immerse the partially cured functional part (i.e., the circular layer) and then the mold is closed with the male (BC) mold half to form a molding assembly comprising Formulation 2A and the partially-cured circular layer immersed therein. The molding assembly is further photo cured by the same UV light for 40 seconds.

After curing, the molding assembly is manually opened and SiHy lens is carefully removed using a tweezer with rubber tips. Then the hydrogel lens is hydrated in deionized water.

SiHy contact lenses with different sized fluorescent central zones have been prepared according to the procedurs described above except changing the amounts of Formulations 2A and 2B as follows: a) 3mg Formulation 2B & 37mg Formulation 2A; b) 6mg Formulation 2B & 34 mg Formulation 2A; c) 9 mg Formulation 2B & 31mg Formulation 2A; d) 12mg Formulation 2B & 28mg Formulation 2A.

Example 3

Polymerizable Compositions

Two polymerizable compositions for forming silicone hydrogel materials are prepared by lending all the required components to have the compositions shown in Table 2.

Table 2

	Components (weight part units)				
	G-PDMS-D2	DMA	PrOH	Ge_PI	SP-MA
Formulation 3A	34.93	35.04	29.49	0.53	0
Formulation 3B	34.76	34.87	29.35	0.53	0.49

Photo-rheology study

Photo-rheology data is acquired by curing the two formulations prepared above by using 452nm LED light (OPSYTEC DR. GROEBEL) with a total irradiance of 54 mW/cm². The results are shown in Figure 3. The replacement of Darocur 1173 with Ge-PI in the Formulation 3A (compared to Formulation 2A) does not cause any effects on G' (G'=120 kPa for Formulation 3A vs G'=120 kPa for Formulation 2A), but slightly increasing the curing time (24 seconds for Formulation 3A vs 20 seconds for Formulation 2A). With the addition of photochromic dye, the curing time is further slower (30 seconds for Formulations 3B) and G' has no significant change (G'=119 kPa for Formulation 3B). Therefore, a comparable lens property is expected for these SiHy lenses under LED curing system.

Fabrication of SiHy lenses with a central photochromic zone

~10mg Formulation 3B is dosed to the center of a female (FC) mold half (made of polypropylene) of a plastic mold (power: -3.0) to form a circular layer, and partially cured by LED light for 2 seconds (OPSYTEC DR. GROEBEL, with a total irradiance of 54 mW/cm²). It is observed that the functional portion (circular layer) is not able to freely flow in the open FC mold half. ~30mg Formulation 3A is added to immerse the partially cured functional portion, and then the mold is closed to form a molding assembly comprising Formulation 3A and the partially-cured circular layer immersed therein. The molding assembly is further photo cured by the same LED light for 60 seconds.

After curing, the molding assembly is manually opened and the SiHy lens is carefully removed using a tweezer with rubber tips. Then the SiHy lens is hydrated in PBS.

The lens with a central photochromic zone is activated by using a black light lamp for 2 minutes (peaks at 365nm, total irradiance of 5mW/cm²). Upon removing the UV light, the SiHy lens gradually faded back to its "off" state. Figure 4 shows the UV spectra (using a Lambda 850 spectrometer) of the central photochromic zone ("on" state 10 and "off" state 11) and peripheral zone (outside of the central photochromic zone) ("on" state 20 and "off" state 21) before and after the activation.
