

METHOD AND APPARATUS FOR COMMUNICATING NETWORK IDENTIFIERS IN A COMMUNICATION SYSTEM

BACKGROUND

Field

[0001] The present disclosure relates generally to wireless communications, and more specifically to a system for communicating (e.g., transmitting and acquiring) network identifiers (IDs) in a wireless communication system, such as an orthogonal frequency division multiplexed (OFDM) wireless communications system.

Background

[0002] Orthogonal frequency division multiplexing (OFDM) is a technique for broadcasting high rate digital signals. In OFDM systems, a single high rate data stream is divided into several parallel low rate substreams, with each substream being used to modulate a respective subcarrier frequency. It should be noted that although the present invention is described in terms of quadrature amplitude modulation, it is equally applicable to phase shift keyed modulation systems.

[0003] The modulation technique used in OFDM systems is referred to as quadrature amplitude modulation (QAM), in which both the phase and the amplitude of the carrier frequency are modulated. In QAM modulation, complex QAM symbols are generated from plural data bits, with each symbol including a real number term and an imaginary number term and with each symbol representing the plural data bits from which it was generated. A plurality of QAM bits are transmitted together in a pattern that can be graphically represented by a complex plane. Typically, the pattern is referred to as a "constellation". By using QAM modulation, an OFDM system can improve its efficiency.

[0004] It happens that when a signal is broadcast, it can propagate to a receiver by more than one path. For example, a signal from a single transmitter can propagate along a straight line to a receiver, and it can also be reflected off of physical objects to propagate along a different path to the receiver. Moreover, it happens that when a system uses a so-called "cellular" broadcasting technique to increase spectral efficiency, a signal intended for a received might be broadcast by more than one transmitter.

Hence, the same signal will be transmitted to the receiver along more than one path. Such parallel propagation of signals, whether man-made (i.e., caused by broadcasting the same signal from more than one transmitter) or natural (i.e., caused by echoes) is referred to as "multipath". It can be readily appreciated that while cellular digital broadcasting is spectrally efficient, provisions must be made to effectively address multipath considerations.

[0005] Fortunately, OFDM systems that use QAM modulation are more effective in the presence of multipath conditions (which, as stated above, must arise when cellular broadcasting techniques are used) than are QAM modulation techniques in which only a single carrier frequency is used. More particularly, in single carrier QAM systems, a complex equalizer must be used to equalize channels that have echoes as strong as the primary path, and such equalization is difficult to execute. In contrast, in OFDM systems the need for complex equalizers can be eliminated altogether simply by inserting a guard interval of appropriate length at the beginning of each symbol. Accordingly, OFDM systems that use QAM modulation are preferred when multipath conditions are expected.

[0006] In a typical trellis coding scheme, the data stream is encoded with a convolutional encoder and then successive bits are combined in a bit group that will become a QAM symbol. Several bits are in a group, with the number of bits per group being defined by an integer "m" (hence, each group is referred to as having an "m-ary" dimension). Typically, the value of "m" is four, five, six, or seven, although it can be more or less.

[0007] After grouping the bits into multi-bit symbols, the symbols are interleaved. By "interleaving" is meant that the symbol stream is rearranged in sequence, to thereby randomize potential errors caused by channel degradation. To illustrate, suppose five words are to be transmitted. If, during transmission of a non-interleaved signal, a temporary channel disturbance occurs. Under these circumstances, an entire word can be lost before the channel disturbance abates, and it can be difficult if not impossible to know what information had been conveyed by the lost word.

[0008] In contrast, if the letters of the five words are sequentially rearranged (i.e., "interleaved") prior to transmission and a channel disturbance occurs, several letters might be lost, perhaps one letter per word. Upon decoding the rearranged letters, however, all five words would appear, albeit with several of the words missing letters.

It will be readily appreciated that under these circumstances, it would be relatively easy for a digital decoder to recover the data substantially in its entirety. After interleaving the m-ary symbols, the symbols are mapped to complex symbols using QAM principles noted above, multiplexed into their respective sub-carrier channels, and transmitted.

SUMMARY

[0009] According to an aspect of the present disclosure, a method for transmitting network identifiers in a communication system is disclosed. The method includes transmitting a first symbol configured to communicate at least timing information; transmitting a second symbol configured to communicate first information including network identification information concerning a first network; and transmitting a third symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network.

[0010] According to another aspect of the present disclosure, a method for determining network identifiers in a communication system in a transceiver is disclosed. The method includes processing a first received symbol configured to communicate first timing information to the transceiver. The method further includes processing a second received symbol configured to communicate first information including network identification information concerning a first network. Finally, the method includes selectively processing a third received symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network when the transceiver is selectively configured to receive data from the second network.

[0011] According to still another aspect of the present disclosure, a processor is disclosed for use in a transmitter. The processor is configured to transmit a first symbol configured to communicate at least timing information and transmit a second symbol configured to communicate first information including network identification information concerning a first network. Additionally, the processor is configured to transmit a third symbol configured to communicate second information including

network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network.

[0012] According to yet another aspect of the present disclosure, a processor is disclosed for use in a transceiver. The processor is configured to process a first received symbol configured to communicate first timing information to the transceiver and process a second received symbol configured to communicate first information including network identification information concerning a first network. The processor is further configured to selectively process a third received symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network when the transceiver is selectively configured to receive data from the second network.

[0013] According to still another aspect of the present disclosure, a processor for use in a transmitter is disclosed having means for transmitting a first symbol configured to communicate at least timing information. The processor also includes means for transmitting a second symbol configured to communicate first information including network identification information concerning a first network, and means for transmitting a third symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network

[0014] According to yet another aspect of the present disclosure, a processor for use in a transceiver is disclosed. The processor includes means for processing a first received symbol configured to communicate first timing information to the transceiver, and means for processing a second received symbol configured to communicate first information including network identification information concerning a first network. The processor also includes means for selectively processing a third received symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification

information concerning the first network when the transceiver is selectively configured to receive data from the second network.

[0015] According to still yet another aspect of the present disclosure, a computer-readable medium encoded with a set of instructions is disclosed. The instructions include an instruction for transmitting a first symbol configured to communicate at least timing information, an instruction for transmitting a second symbol configured to communicate first information including network identification information concerning a first network, and an instruction for transmitting a third symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network.

[0016] According to one more aspect of the present disclosure a computer-readable medium encoded with a set of instructions is disclosed. The instructions include an instruction for processing a first received symbol configured to communicate at least timing information to the transceiver; an instruction for processing a second received symbol configured to communicate first information including network identification information concerning a first network; and an instruction for selectively processing a third received symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network when the transceiver is selectively configured to receive data from the second network.

BRIEF DESCRIPTION OF THE DRAWINGS

[0017] FIG. 1a shows a channel interleaver in accordance with an embodiment;

[0018] FIG. 1b shows a channel interleaver in accordance with another embodiment;

[0019] FIG. 2a shows code bits of a turbo packet placed into an interleaving buffer in accordance with an embodiment;

[0020] FIG. 2b shows an interleaver buffer arranged into an N/m rows by m columns matrix in accordance with an embodiment;

[0021] FIG. 3 illustrates an interleaved interlace table in accordance with an embodiment;

[0022] FIG. 4 shows a channelization diagram in accordance with an embodiment;

[0023] FIG. 5 shows a channelization diagram with all one's shifting sequence resulting in long runs of good and poor channel estimates for a particular slot, in accordance with an embodiment; and

[0024] FIG. 6 shows a Channelization diagram with all two's shifting sequence resulting in evenly spread good and poor channel estimate interlaces; and

[0025] FIG. 7 shows a wireless device configured to implement interleaving in accordance with an embodiment.

[0026] FIG. 8 shows a block diagram of an exemplary frame check sequence computation for a physical layer packet.

[0027] FIG. 9 shows a diagram of the duration of an exemplary OFDM symbol.

[0052] FIG. 34 shows an exemplary signal constellation for Layered Modulation

[0053] FIG. 35 shows a diagram of interlace allocations to FDM Pilots.

[0054] FIG. 36 shows a diagram of interlace allocations to slots

[0055] FIG.37 shows a block diagram of an exemplary OFDM common operation.

[0056] FIG. 38 shows a diagram illustrating an overlap of windowed OFDM Symbols according to an example. FIG. 33 shows an exemplary signal constellation for 16-QAM Modulation

[0057] FIG. 39 shows an exemplary frame preamble including symbols TDM 1, TDM 2, and TDM 3.

[0058] FIG. 40 shows a diagram of interlace allocations to for WOI pilot channels in symbol TDM 2 of FIG. 39.

[0059] FIG. 41 shows a diagram of interlace allocations for WOI and LOI pilot channels in symbol TDM 3 of FIG. 39.

[0060] FIG.42 shows an exemplary symbol sampling period for at least one of symbols TDM 2 and TDM 3 of FIG. 39..

[0061] FIG. 43 shows a diagram illustrating an exemplary transceiver for receiving the symbols of FIG. 39.

[0062] FIG. 44 shows an exemplary flow diagram of a method for transmitting wireless symbols (e.g., TDM1, TDM2, and TDM3) for communicating information to a transceiver for timing acquisition

[0063] FIG. 45 shows an exemplary flow diagram of a method for a method for determining network identifiers in a communication system in a transceiver.

[0064] FIG. 46 shows an exemplary block diagram of an apparatus for transmitting wireless symbols, such as those shown in FIG. 39.

[0065] FIG. 47 shows an exemplary block diagram of an apparatus for receiving wireless symbols, such as those shown in FIG. 39.

DETAILED DESCRIPTION

[0066] In an embodiment, a channel interleaver comprises a bit interleaver and a symbol interleaver. Figure 1 shows two types of channel interleaving schemes. Both schemes use bit interleaving and interlacing to achieve maximum channel diversity.

[0067] Figure 1a shows a channel interleaver in accordance with an embodiment. Figure 1b shows a channel interleaver in accordance with another embodiment. The interleaver of figure 1b uses bit-interleaver solely to achieve m-ary modulation diversity and uses a two-dimension interleaved interlace table and run-time slot-to-interlace mapping to achieve frequency diversity which provides better interleaving performance without the need for explicit symbol interleaving.

[0068] Figure 1a shows Turbo coded bits 102 input into bit interleaving block 104. Bit interleaving block 104 outputs interleaved bits, which are input into constellation symbol mapping block 106. Constellation symbol mapping block 106 outputs constellation symbol mapped bits, which are input into constellation symbol interleaving block 108. Constellation symbol interleaving block 108 outputs constellation symbol interleaved bits into channelization block 110. Channelization block 110 interlaces the constellation symbol interleaved bits using an interlace table 112 and outputs OFDM symbols 114.

[0069] Figure 1b shows Turbo coded bits 152 input into bit interleaving block 154. Bit interleaving block 154 outputs interleaved bits, which are input into constellation symbol mapping block 156. Constellation symbol mapping block 156 outputs constellation symbol mapped bits, which are input into channelization block 158. Channelization block 158 channelizes the constellation symbol interleaved bits using an interleaved interlace table and dynamic slot-interlace mapping 160 and outputs OFDM symbols 162.

[0070] Bit Interleaving for modulation diversity

[0071] The interleaver of figure 1b uses bit interleaving 154 to achieve modulation diversity. The code bits 152 of a turbo packet are interleaved in such a pattern that adjacent code bits are mapped into different constellation symbols. For example, for 2m-Ary modulation, the N bit interleaver buffer are divided into N/m blocks. Adjacent code bits are written into adjacent blocks sequentially and then are read out one by one from the beginning of the buffer to the end in the sequential order, as shown in Figure 2a (Top). This guarantees that adjacent code bits be mapped to different constellation

symbols. Equivalently, as is illustrated in Figure 2b (Bottom), the interleaver buffer is arranged into an N/m rows by m columns matrix. Code bits are written into the buffer column by column and are read out row by row. To avoid the adjacent code bit to be mapped to the same bit position of the constellation symbol due to the fact that certain bits of a constellation symbol are more reliable than the others for 16QAM depending on the mapping, for example, the first and third bits are more reliable than the second and fourth bits, rows shall be read out from left to right and right to left alternatively.

[0072] Figure 2a shows code bits of a turbo packet 202 placed into an interleaving buffer 204 in accordance with an embodiment. Figure 2b is an illustration of bit interleaving operation in accordance with an embodiment. Code bits of a Turbo packet 250 are placed into an interleaving buffer 252 as shown in figure 2b. The interleaving buffer 252 is transformed by swapping the second and third columns, thereby creating interleaving buffer 254, wherein $m=4$, in accordance with an embodiment. Interleaved code bits of a Turbo packet 256 are read from the interleaving buffer 254.

[0073] For simplicity, a fixed $m=4$ may be used, if the highest modulation level is 16 and if code bit length is always divisible by 4. In this case, to improve the separation for QPSK, the middle two columns are swapped before being read out. This procedure is depicted in Figure 2b (Bottom). It would be apparent to those skilled in the art that any two columns may be swapped. It would also be apparent to those skilled in the art that the columns may be placed in any order. It would also be apparent to those skilled in the art that the rows may be placed in any order.

[0074] In another embodiment, as a first step, the code bits of a turbo packet 202 are distributed into groups. Note that the embodiments of both figure 2a and figure 2b also distribute the code bits into groups. However, rather than simply swapping rows or columns, the code bits within each group are shuffled according to a group bit order for each given group. Thus, the order of four groups of 16 code bits after being distributed into groups may be {1, 5, 9, 13} {2, 6, 10, 14} {3, 7, 11, 15} {4, 8, 12, 16} using a simple linear ordering of the groups and the order of the four groups of 16 code bits after shuffling may be {13, 9, 5, 1} {2, 10, 6, 14} {11, 7, 15, 3} {12, 8, 4, 16}. Note that swapping rows or columns would be a regressive case of this intra-group shuffling.

[0075] **Interleaved Interlace for frequency diversity**

[0076] In accordance with an embodiment, the channel interleaver uses interleaved interlace for constellation symbol interleaving to achieve frequency diversity. This

eliminates the need for explicit constellation symbol interleaving. The interleaving is performed at two levels:

[0077] Within or Intra Interlace Interleaving: In an embodiment, 500 subcarriers of an interlace are interleaved in a bit-reversal fashion.

[0078] Between or Inter Interlace Interleaving: In an embodiment, eight interlaces are interleaved in a bit-reversal fashion.

[0079] It would be apparent to those skilled in the art that the number of subcarriers can be other than 500. It would also be apparent to those skilled in the art that the number of interlaces can be other than eight.

[0080] Note that since 500 is not power of 2, a reduced-set bit reversal operation shall be used in accordance with an embodiment. The following code shows the operation:

```
vector<int> reducedSetBitRev(int n)
{
    int m=exponent(n);
    vector<int> y(n);
    for (int i=0, j=0; i<n; i++,j++)
    {
        int k;
        for (; (k=bitRev(j,m))>=n; j++);
        y[i]=k;
    }
    return y;
}
```

[0081] where $n=500$, m is the smallest integer such that $2^m > n$ which is 8, and bitRev is the regular bit reversal operation.

[0082] The symbols of the constellation symbol sequence of a data channel is mapped into the corresponding subcarriers in a sequential linear fashion according to the assigned slot index, determined by a Channelizer, using the interlace table as is depicted in Figure 3, in accordance with an embodiment.

[0083] Figure 3 illustrates an interleaved interlace table in accordance with an embodiment. Turbo packet 302, constellation symbols 304, and interleaved interlace table 306 are shown. Also shown are interlace 3 (308), interlace 4 (310), interlace 2 (312), interlace 6 (314), interlace 1 (316), interlace 5 (318), interlace 3 (320), and interlace 7 (322).

[0084] In an embodiment, one out of the eight interlaces is used for pilot, i.e., Interlace 2 and Interlace 6 is used alternatively for pilot. As a result, the Channelizer can use seven interlaces for scheduling. For convenience, the Channelizer uses Slot as a scheduling unit. A slot is defined as one interlace of an OFDM symbol. An Interlace Table is used to map a slot to a particular interlace. Since eight interlaces are used, there are then eight slots. Seven slots will be set aside for use for Channelization and one slot for Pilot. Without loss of generality, Slot 0 is used for the Pilot and Slots 1 to 7 are used for Channelization, as is shown in Figure 4 where the vertical axis is the slot index 402, the horizontal axis is the OFDM symbol index 404 and the bold-faced entry is the interlace index assigned to the corresponding slot at an OFDM symbol time.

[0085] Figure 4 shows a channelization diagram in accordance with an embodiment. Figure 4 shows the slot indices reserved for the scheduler 406 and the slot index reserved for the Pilot 408. The bold faced entries are interlace index numbers. The number with square is the interlace adjacent to pilot and consequently with good channel estimate.

[0086] The number surrounded with a square is the interlace adjacent to the pilot and consequently with good channel estimate. Since the Scheduler always assigns a chunk of contiguous slots and OFDM symbols to a data channel, it is clear that due to the inter-interlace interleaving, the contiguous slots that are assigned to a data channel will be mapped to discontinuous interlaces. More frequency diversity gain can then be achieved.

[0087] However, this static assignment (i.e., the slot to physical interlace mapping table does not change over time where the scheduler slot table does not include the pilot slot) does suffer one problem. That is, if a data channel assignment block (assuming rectangular) occupies multiple OFDM symbols, the interlaces assigned to the data channel does not change over the time, resulting in loss of frequency diversity. The remedy is simply cyclically shifting the Scheduler interlace table (i.e., excluding the Pilot interlace) from OFDM symbol to OFDM symbol.

[0088] Figure 5 depicts the operation of shifting the Scheduler interlace table once per OFDM symbol. This scheme successfully destroys the static interlace assignment problem, i.e., a particular slot is mapped to different interlaces at different OFDM symbol time.

[0089] Figure 5 shows a channelization diagram with all one's shifting sequence resulting in long runs of good and poor channel estimates for a particular slot 502, in accordance with an embodiment. Figure 5 shows the slot indices reserved for the scheduler 506 and the slot index reserved for the Pilot 508. Slot symbol index 504 is shown on the horizontal axis.

[0090] However, it is noticed that slots are assigned four continuous interlaces with good channel estimates followed by long runs of interlaces with poor channel estimates in contrast to the preferred patterns of short runs of good channel estimate interlaces and short runs of interlaces with poor channel estimates. In the figure, the interlace that is adjacent to the pilot interlace is marked with a square. A solution to the long runs of good and poor channel estimates problem is to use a shifting sequence other than the all one's sequence. There are many sequences can be used to fulfill this task. The simplest sequence is the all two's sequence, i.e., the Scheduler interlace table is shifted twice instead of once per OFDM symbol. The result is shown in Figure 6 which significantly improves the Channelizer interlace pattern. Note that this pattern repeats every $2 \times 7 = 14$ OFDM symbols, where 2 is the Pilot interlace staggering period and 7 is the Channelizer interlace shifting period.

[0091] To simplify the operation at both transmitters and receivers, a simple formula can be used to determine the mapping from slot to interlace at a given OFDM symbol time

$$[0092] \quad i = \Re' \{ (N - ((R \times t) \% N) + s - 1) \% N \}$$

where

[0093] . $N = I - 1$ is the number of interlaces used for traffic data scheduling, where I is the total number of interlaces;

[0094] . $i \in \{0, 1, \dots, I - 1\}$, excluding the pilot interlace, is the interlace index that Slot s at OFDM symbol t maps to;

[0095] . $t = 0, 1, \dots, T-1$ is the OFDM symbol index in a super frame, where T is the total number of OFDM symbols in a frame¹;

[0096] . $s = 1, 2, \dots, S-1$ is the slot index where S is the total number of slots;

[0097] . R is the number of shifts per OFDM symbol;

[0098] . $\mathcal{R}'$ is the reduced-set bit-reversal operator. That is, the interlace used by the Pilot shall be excluded from the bit-reversal operation.

[0099] Example: In an embodiment, $I=8$, $R=2$. The corresponding Slot-Interlace mapping formula becomes

$$[00100] \quad i = \mathcal{R}'\{(7 - ((2 \times t) \% 7) + s - 1) \% 7\}$$

[00101] where $\mathcal{R}'$ corresponds to the following table:

$$\underline{x \Rightarrow \mathcal{R}'\{x\}}$$

$$0 \Rightarrow 0$$

$$1 \Rightarrow 4$$

$$2 \Rightarrow 2 \text{ or } 6$$

$$3 \Rightarrow 1$$

$$4 \Rightarrow 5$$

$$5 \Rightarrow 3$$

$$6 \Rightarrow 7$$

[00102] This table can be generated by the following code:

```
int reducedSetBitRev(int x, int exclude, int n)
{
    int m=exponent(n);
    int y;
    for (int i=0; j=0; i<=x; i++, j++)
    {
        for (; (y=bitRev(j, m))==exclude; j++);
    }
}
```

¹ OFDM symbol index in a superframe instead of in a frame gives additional diversity to frames since the number of OFDM symbols in a frame in the current design is not divisible by 14.

```

    return y;
}

```

where $m=3$ and bitRev is the regular bit reversal operation.

[00103] For OFDM symbol $t=11$, Pilot uses Interlace 6. The mapping between Slot and Interlace becomes:

[00104] Slot 1 maps to interlace of $\Re'\{(7 - (2 \times 11) \% 7 + 1 - 1) \% 7\} = \Re\{6\} = 7$;

[00105] Slot 2 maps to interlace of $\Re'\{(7 - (2 \times 11) \% 7 + 2 - 1) \% 7\} = \Re\{0\} = 0$;

[00106] Slot 3 maps to interlace of $\Re'\{(7 - (2 \times 11) \% 7 + 3 - 1) \% 7\} = \Re\{1\} = 4$;

[00107] Slot 4 maps to interlace of $\Re'\{(7 - (2 \times 11) \% 7 + 4 - 1) \% 7\} = \Re\{2\} = 2$;

[00108] Slot 5 maps to interlace of $\Re'\{(7 - (2 \times 11) \% 7 + 5 - 1) \% 7\} = \Re\{3\} = 1$;

[00109] Slot 6 maps to interlace of $\Re'\{(7 - (2 \times 11) \% 7 + 6 - 1) \% 7\} = \Re\{4\} = 5$;

[00110] Slot 7 maps to interlace of $\Re'\{(7 - (2 \times 11) \% 7 + 7 - 1) \% 7\} = \Re\{5\} = 3$.

[00111] The resulting mapping agrees with the mapping in Figure 6. Figure 6 shows a Channelization diagram with all two's shifting sequence resulting in evenly spread good and poor channel estimate interlaces.

[00112] In accordance with an embodiment, an interleaver has the following features:

[00113] The bit interleaver is designed to taking advantage of m-Ary modulation diversity by interleaving the code bits into different modulation symbols;

[00114] The "symbol interleaving" designed to achieve frequency diversity by INTRA-interlace interleaving and INTER-interlace interleaving;

[00115] Additional frequency diversity gain and channel estimation gain are achieved by changing the slot-interlace mapping table from OFDM symbol to OFDM symbol. A simple rotation sequence is proposed to achieve this goal.

[00116] Figure 7 shows a wireless device configured to implement interleaving in accordance with an embodiment. Wireless device 702 comprises an antenna 704, duplexer 706, a receiver 708, a transmitter 710, processor 712, and memory 714. Processor 712 is capable of performing interleaving in accordance with an embodiment. The processor 712 uses memory 714 for buffers or data structures to perform its operations.

[00117] The following description includes details of further embodiments.

[00118] The transmission unit of the Physical layer is a Physical layer packet. A Physical layer packet has a length of 1000 bits. A Physical layer packet carries one MAC layer packet.

Physical Layer Packet Format

[00119] The Physical layer packet shall use the following format:

Field	Length (bits)
MAC Layer Packet	976
FCS	16
Reserved	2
TAIL	6

where the MAC Layer Packet is a MAC layer packet from the OIS, Data or Control Channel MAC protocol; FCS is a Frame check sequence; Reserved is reserved bits which the FLO network shall set this field to zero and the FLO device shall ignore this field; and TAIL is encoder tail bits, which shall be set to all '0's.

[00120] The following table illustrates the format of the Physical layer packet:

Bit Transmission Order

[00121] Each field of the Physical layer packet shall be transmitted in sequence such that the most significant bit (MSB) is transmitted first and the least significant bit (LSB) is transmitted last. The MSB is the left-most bit in the figures of the document.

Computation of the FCS Bits

[00122] The FCS computation described here shall be used for computing the FCS field in the Physical layer packet.

[00123] The FCS shall be a CRC calculated using the standard CRC-CCITT generator polynomial:

$$g(x) = x^{16} + x^{12} + x^5 + 1.$$

[00124] The FCS shall be equal to the value computed according to the following described procedure also illustrated in FIG. 8.

[00125] All shift-register elements shall be initialized to '1's. It is noted that initialization of the register to ones causes the CRC for all-zero data to be non-zero.

[00126] The switches shall be set in the up position.

[00127] The register shall be clocked once for each bit of the physical layer packet except for the FCS, Reserved, and TAIL bits. The physical layer packet shall be read from the MSB to LSB.

[00128] The switches shall be set in the down position so that the output is a modulo-2 addition with a '0' and the successive shift-register inputs are '0's.

[00129] The register shall be clocked an additional 16 times for the 16 FCS bits.

[00130] The output bits constitute all fields of the Physical layer packets except the Reserved and TAIL fields.

FLO Network Requirements

[00131] The following discussion section defines requirements specific to the FLO network equipment and operation.

Transmitter

[00132] The following requirements shall apply to the FLO network transmitter. The transmitter shall operate in one of eight 6 MHz wide bands, but may also supports transmit bandwidths of 5, 7, and 8 MHz. Each 6 MHz wide transmit band allocation is called a FLO RF Channel. Each FLO RF Channel shall be denoted by an index $j \in \{1, 2, \dots, 8\}$. The transmit band and the band center frequency for each FLO RF channel index shall be as specified in Table 1 below.

FLO RF Channel Number j	FLO Transmit Band (MHz)	Band Center Frequency f_c (MHz)
1	698 - 704	701

2	704 - 710	707
3	710 - 716	713
4	716 - 722	719
5	722 - 728	725
6	728 - 734	731
7	734 - 740	737
8	740 - 746	743

Table 1: FLO RF Channel Number and the Transmit Band Frequencies

[00133] The maximum frequency difference between the actual transmit carrier frequency and the specified transmit frequency shall be less than $\pm 2 \times 10^{-9}$ of the band center frequency in Table 1.

[00134] It is noted that in Band Spectral Characteristics and out of Band Spectrum Mask are to be determined.

[00135] Power Output Characteristics are such that the transmit ERP shall be less than 46.98 dBW, which corresponds to 50 kW.

OFDM Modulation Characteristics

[00136] The modulation used on the air-link is Orthogonal Frequency Division Multiplexing (OFDM). The smallest transmission interval corresponds to one OFDM symbol period. The OFDM transmit symbol is comprised of many separately modulated sub-carriers. The FLO system shall use 4096 sub-carriers, numbered 0 through 4095. These sub-carriers are divided into two separate groups.

[00137] The first group of sub-carriers is guard Sub-carriers Of the available 4096 sub-carriers, 96 shall be unused. These unused sub-carriers are called guard sub-carriers. No energy shall be transmitted on the guard sub-carriers. Sub-carriers numbered 0 through 47, 2048, and 4049 through 4095 shall be used as guard sub-carriers.

[00138] The second group is active Sub-carriers. The active sub-carriers shall be a group of 4000 sub-carriers with indices $k \in \{48..2047, 2049..4048\}$. Each active sub-carrier shall carry a modulation symbol.

[00139] Concerning sub-carrier spacing in the FLO system, the 4096 sub-carriers shall span a bandwidth of 5.55 MHz at the center of the 6 MHz FLO RF Channel. The sub-carrier spacing, $(\Delta f)_{sc}$ shall be given by:

$$(\Delta f)_{sc} = \frac{5.55 \times 10^6}{4096} = 1.35498046875 \text{ kHz}$$

[00140] Concerning sub-carrier frequency, the frequency of the sub-carrier with index i in the k^{th} FLO RF Channel (see Table 1 above), $f_{sc}(k, i)$, shall be computed as per the following equation:

$$f_{sc}(k, i) = f_c(k) + (i - 2048) \times (\Delta f)_{sc}$$

where $f_c(k)$ is the center frequency for the k^{th} FLO RF Channel, and $(\Delta f)_{sc}$ is the sub-carrier spacing.

Sub-carrier Interlaces

[00141] The active sub-carriers shall be sub-divided into 8 interlaces indexed from 0 through 7. Each interlace shall consist of 500 sub-carriers. The sub-carriers in an interlace shall be spaced $[8 \times (\Delta f)_{sc}]$ Hz apart (with the exception of interlace zero, where two sub-carriers in the middle of this interlace are separated by $16 \times (\Delta f)_{sc}$, since the sub-carrier with index 2048 is not used) in frequency, with $(\Delta f)_{sc}$ being the sub-carrier spacing.

[00142] The sub-carriers in each interlace shall span 5.55 MHz of the FLO RF Channel bandwidth. An active sub-carrier with index i shall be allocated to interlace I_j , where $j = i \bmod 8$. The sub-carrier indices in each interlace shall be arranged sequentially in ascending order. The numbering of sub-carriers in an interlace shall be in the range 0, 1, ..., 499.

Frame and Channel Structure

[00143] The transmitted signal is organized into superframes. Each superframe shall have duration T_{SF} equal to 1s, and shall consist of 1200 OFDM symbols. The OFDM symbols in a superframe shall be numbered 0 through 1199. The OFDM symbol interval T_s shall be $833.33... \mu s$. The OFDM symbol consists of a number of time-

domain baseband samples, called OFDM chips. These chips shall be transmitted at a rate of 5.55×10^6 per second.

[00144] The total OFDM symbol interval T_s' is comprised of four parts: a useful part with duration T_U , a flat guard interval with duration T_{FGI} and two windowed intervals of duration T_{WGI} on the two sides, as illustrated in FIG. 9. There shall be an overlap of T_{WGI} between consecutive OFDM symbols (see FIG. 9).

[00145] The effective OFDM symbol interval shall be $T_s = T_{WGI} + T_{FGI} + T_U$,

$$\text{where } \begin{cases} T_U = 4096 \text{ chips} = \frac{4096}{5.55 \times 10^6} = 738.018018... \mu\text{s} \\ T_{FGI} = 512 \text{ chips} = \frac{512}{5.55 \times 10^6} = 92.252252... \mu\text{s} \\ T_{WGI} = 17 \text{ chips} = \frac{17}{5.55 \times 10^6} = 3.063063... \mu\text{s} \end{cases}$$

[00146] The total symbol duration in FIG. 9 shall be $T_s' = T_s + T_{WGI}$.

[00147] The effective OFDM symbol duration shall henceforth be referred to as the OFDM symbol interval. During an OFDM symbol interval, a modulation symbol shall be carried on each of the active sub-carriers.

[00148] The FLO Physical layer channels are the TDM Pilot Channel, the FDM Pilot Channel, the OIS Channel, and the Data Channel. The TDM Pilot Channel, the OIS Channel, and the Data Channel shall be time division multiplexed over a superframe. The FDM Pilot Channel shall be frequency division multiplexed with the OIS Channel and the Data Channel over a superframe as illustrated in FIG. 10.

[00149] The TDM Pilot Channel is comprised of the TDM Pilot 1 Channel, the Wide-area Identification Channel (WIC), the Local-area Identification Channel (LIC), the TDM Pilot 2 Channel, the Transition Pilot Channel (TPC) and the Positioning Pilot Channel (PPC). The TDM Pilot 1 Channel, the WIC, the LIC and the TDM Pilot 2 Channel, shall each span one OFDM symbol and appear at the beginning of a superframe. A Transition Pilot Channel (TPC) spanning one OFDM symbol shall precede and follow each Wide-area and Local-area Data or OIS Channel transmission. The TPC flanking the Wide-area Channel (Wide-area OIS or Wide-area Data) is called the Wide-area Transition Pilot Channel (WTPC). The TPC flanking the Local-area

channel (Local-area OIS or Local-area Data Channel) transmission is called the Local-area Transition Pilot Channel (LTPC). The WTPC and the LTPC shall each occupy 10 OFDM symbols and together occupy 20 OFDM symbols in a superframe. The PPC shall have variable duration and its status (presence or absence and duration) shall be signaled over the OIS Channel. When present, it shall span 6, 10, or 14 OFDM symbols at the end of the superframe. When PPC is absent, two OFDM symbols shall be reserved at the end of the superframe.

[00150] The OIS Channel shall occupy 10 OFDM symbols in a superframe and shall immediately follow the first WTPC OFDM symbol in a superframe. The OIS Channel is comprised of the Wide-area OIS Channel and the Local-area OIS Channel. The Wide-area OIS Channel and the Local-area OIS Channel shall each have duration of 5 OFDM symbols and shall be separated by two TPC OFDM symbols.

[00151] The FDM Pilot Channel shall span 1174, 1170, 1166, or 1162 OFDM. These values correspond to either 2 Reserved OFDM symbols or 6, 10 and 14 PPC OFDM symbols, respectively, being present in each superframe symbols in a superframe. It is noted that these values correspond to either 2 Reserved OFDM symbols or 6, 10 and 14 PPC OFDM symbols, respectively, being present in each superframe. The FDM Pilot channel is frequency division multiplexed with Wide-area and Local-area OIS and Data Channels.

[00152] The Data Channel shall span 1164, 1160, 1156 or 1152 OFDM symbols. It is noted that these values correspond to either 2 Reserved OFDM symbols or 6, 10 and 14 PPC OFDM symbols, respectively, being present in each superframe. The Data Channel transmission plus the 16 TPC OFDM symbol transmissions immediately preceding or following each data channel transmission are divided into 4 frames.

[00153] Let frame parameters be set where P is the number of OFDM symbols in the PPC or the number of Reserved OFDM symbols in the case where the PPC is absent in a superframe; W is the number of OFDM symbols associated with the Wide-area Data Channel in a frame; L is the number of OFDM symbols associated with the Local-area Data Channel in a frame; and F is the number of OFDM symbols in a frame. These frame parameters may then be related by the following set of equations:

$$F = 295 - \frac{P - 2}{4}$$

$$F = W + L + 4$$

[00154] FIG. 10 illustrates the superframe and the channel structure in terms of P, W, and L. When the PPC is absent, each frame shall span 295 OFDM symbols and have duration T_F equal to 245.8333. ms. It is noted there are two Reserved OFDM symbols at the end of each superframe. When the PPC is present at the end of the superframe, each frame shall span a variable number of OFDM symbols as specified in Table 3 below.

Number of PPC OFDM Symbols	Frame Duration (F) in units of OFDM symbols	Frame Duration in ms
6	294	245
10	293	244.166...
14	292	243.333...

Table 3 - Frame Duration for Different Numbers of PPC OFDM Symbols

[00155] The Data Channel during each frame shall be time division multiplexed between the Local-area Data Channel and the Wide-area Data Channel. The fraction of the frame allocated to Wide-area Data is $\frac{W}{W+L} \times 100$ % and may vary from 0 to 100%.

[00156] The Physical layer packets transmitted over the OIS Channel are called OIS packets and the Physical layer packets transmitted over the Data Channel are called Data packets.

Flow Components and Layered Modulation

[00157] The audio or video content associated with a flow multicast over the FLO network may be sent in two components, i.e. a base (B) component that enjoys widespread reception and an enhancement (E) component that improves upon the audio-visual experience provided by the base component over a more limited coverage area.

[00158] The base and the enhancement component Physical layer packets are jointly mapped to modulation symbols. This FLO feature is known as layered modulation.

MediaFLO Logical Channel

[00159] The Data packets transmitted by the Physical layer are associated with one or more virtual channels called MediaFLO Logical Channels (MLC). An MLC is a decodable component of a FLO service that is of independent reception interest to a FLO device. A service may be sent over multiple MLCs. However, the base and enhancement component of an audio or video flow associated with a service shall be transmitted over a single MLC.

FLO Transmit Modes

[00160] The combination of modulation type and the inner code rate is called the “transmit mode”. The FLO system shall support the twelve transmit modes listed in Table 4 found below.

[00161] In the FLO network, the transmit mode is fixed when an MLC is instantiated and is changed infrequently. This restriction is imposed in order to maintain a constant coverage area for each MLC.

Mode Number	Modulation	Turbo Code Rate
0	QPSK	1/3
1	QPSK	1/2
2	16-QAM	1/3
3	16-QAM	1/2
4	16-QAM	2/3
5 ²	QPSK	1/5
6	Layered Modulation with energy ratio 4	1/3
7	Layered Modulation with energy ratio 4	1/2
8	Layered Modulation with energy ratio 4	2/3
9	Layered Modulation with energy ratio 6.25	1/3
10	Layered Modulation with energy ratio 6.25	1/2
11	Layered Modulation with energy ratio 6.25	2/3

Table 4. FLO Transmit Modes

² This mode is used for the OIS channel only.

FLO Slots

[00162] In the FLO network, the smallest unit of bandwidth allocated to a MLC over an OFDM symbol corresponds to a group of 500 modulation symbols. This group of 500 modulation symbols is called a slot. The scheduler function (in the MAC layer) allocates slots to MLCs during the data portion of the superframe. When the scheduler function allocates bandwidth for transmission to a MLC in an OFDM symbol, it does so in integer units of slots.

[00163] There are 8 slots during every OFDM symbol except for the TDM Pilot 1 Channel in a superframe. These slots shall be numbered 0 through 7. The WIC and LIC channels shall each occupy 1 slot. The TDM Pilot 2 Channel shall occupy 4 slots. The TPC (Wide-area and Local-area) shall occupy all 8 slots. The FDM Pilot Channel shall occupy 1 slot with index 0 and the OIS/Data Channel may occupy up to 7 slots with indices 1 through 7. Each slot shall be transmitted over an interlace. The mapping from slot to interlace varies from OFDM symbol to OFDM symbol and is described in further detail to follow.

FLO Data Rates

[00164] In the FLO system the calculation of data rates is complicated by the fact that different MLCs may utilize different modes. The computation of data rates is simplified by assuming that all MLCs use the same transmit mode. Table 5 below gives the Physical layer data rates for the different transmit modes assuming all 7 data slots are used.

Transmit Mode	Slots per Physical Layer Packet	Physical Layer Data Rate (Mbps)
0	3	2.8
1	2	4.2
2	3/2	5.6
3	1	8.4
4	3/4	11.2
5	5	1.68
6	3	5.6
7	2	8.4
8	3/2	11.2
9	3	5.6
10	2	8.4
11	3/2	11.2

Table 5 - FLO Transmit Modes and Physical Layer Data Rates

[00165] It is noted that in Table 5 above that for the values in the column labeled “Physical layer data rate,” the overhead due to the TDM Pilot channel and the outer code is not subtracted. This is the rate at which data is transmitted during the Data channel. For modes 6 through 11, the rate quoted is the combined rate of the two components. The rate for each component will be half of this value.

FLO Physical Layer Channels

[00166] The FLO Physical layer is comprised of the following sub-channels: the TDM Pilot Channel; the Wide-area OIS Channel; the Local-area OIS Channel; the Wide-area FDM Pilot Channel; the Local-area FDM Pilot Channel; the Wide-area Data Channel; and the Local-area Data Channel

TDM Pilot Channel

[00167] The TDM Pilot Channel is comprised of the following component channels: TDM Pilot 1 Channel; wide-area identification channel (WIC); Local-area Identification Channel (LIC); and TDM Pilot 2 Channel; Transition Pilot Channel (TPC)

TDM Pilot 1 Channel

[00168] The TDM Pilot 1 Channel shall span one OFDM symbol. It shall be transmitted at the OFDM symbol index 0 in the superframe. It signals the start of a new superframe. It may be used by the FLO device for determining the coarse OFDM symbol timing, the superframe boundary and the carrier frequency offset.

[00169] The TDM Pilot 1 waveform shall be generated in the transmitter using the steps illustrated in FIG. 11.

TDM Pilot 1 Sub-carriers

[00170] The TDM Pilot 1 OFDM symbol shall be comprised of 124 non-zero sub-carriers in the frequency domain, which are uniformly spaced among the Active sub-carriers. The i^{th} TDM Pilot 1 sub-carrier shall correspond to the sub-carrier index j defined as follows:

$$j = \begin{cases} 64 + (i) \times 32, \forall i \in \{0, 1..61\} \\ 64 + (i+1) \times 32, \forall i \in \{62, \dots, 123\}. \end{cases}$$

[00171] Note that the TDM Pilot 1 Channel does not use the sub-carrier with index 2048.

TDM Pilot 1 Fixed Information Pattern

[00172] The TDM Pilot 1 sub-carriers shall be modulated with a fixed information pattern. This pattern shall be generated using a 20-tap linear feedback shift register (LFSR) with generator sequence $h(D) = D^{20} + D^{17} + 1$ and initial state '11110000100000000000'. Each output bit shall be obtained as follows: if the LFSR state is the vector $[s_{20} s_{19} s_{18} s_{17} s_{16} s_{15} s_{14} s_{13} s_{12} s_{11} s_{10} s_9 s_8 s_7 s_6 s_5 s_4 s_3 s_2 s_1]$ then, the output bit shall be $[s_{19} \oplus s_4]$, where $\oplus$ denotes modulo-2 addition, which corresponds to the mask associated with slot 1 (see Table 6, which follows later). The LFSR structure shall be as specified in FIG. 12

[00173] The fixed information pattern shall correspond to the first 248 output bits. The first 35-bits of the fixed pattern shall be '11010100100110110111001100101100001', with '110' appearing first.

[00174] The 248-bit TDM Pilot 1 fixed pattern is called the TDM Pilot 1 Information packet and is denoted as P1I.

[00175] Each group of two consecutive bits in the P1I packet shall be used to generate QPSK modulation symbols.

Modulation Symbols Mapping

[00176] In the TDM Pilot 1 information packet, each group of two consecutive bits, P1I(2i) and P1I(2i+1), $i = 0, 1, \dots, 123$, which are labeled as s_0 and s_1 , respectively, shall be mapped into a complex modulation symbol $MS = (mI, mQ)$ with $D = 4$ as specified in Table 6 below. This factor is calculated using the fact that only 124 of the 4000

available carriers are being used. $\sqrt{\frac{1}{2} \times \frac{4000}{124}} \cong 4$.

Input bits		Modulation Symbols MS	
s_1	s_0	mI	mQ
0	0	D	D
0	1	-D	D
1	0	D	-D
1	1	-D	-D

Table 6 - QPSK Modulation Table

[00177] FIG. 13 shows the signal constellation for the QPSK modulation.

Modulation Symbols to Sub-carrier Mapping

[00178] The i^{th} modulation symbol $MS(i)$, $i = 0, 1, \dots, 123$, shall be mapped to the sub-carrier with index j as specified previously.

OFDM Common Operation

[00179] The modulated TDM Pilot 1 sub-carriers shall undergo common operations as will be discussed later.

Wide-area Identification Channel (WIC)

[00180] The Wide-area Identification Channel (WIC) shall span one OFDM symbol. It shall be transmitted at OFDM symbol index 1 in a superframe. It follows the TDM Pilot 1 OFDM symbol. This is an overhead channel that is used for conveying the Wide-area Differentiator information to FLO receivers. All transmit waveforms within a Wide-area (which includes Local-area channels but excludes the TDM Pilot 1 Channel

and the PPC) shall be scrambled using the 4-bit Wide-area Differentiator corresponding to that area.

[00181] For the WIC OFDM symbol in a superframe only 1 slot shall be allocated. The allocated slot shall use as input a 1000-bit fixed pattern, with each bit set to zero. The input bit pattern shall be processed according to the steps illustrated in FIG. 14. No processing shall be performed for the un-allocated slots.

Slot Allocation

[00182] The WIC shall be allocated the slot with index 3. The allocated and un-allocated slots in the WIC OFDM symbol are illustrated in FIG. 15. The slot index chosen is the one that maps to interlace 0 for OFDM symbol index 1, which will be discussed later.

Filling of Slot Buffer

[00183] The buffer for the allocated slot shall be completely filled with a fixed pattern consisting of 1000 bits, with each bit set to '0'. The buffers for the un-allocated slots shall be left empty.

Slot Scrambling

[00184] The bits of each allocated slot buffer shall be XOR'd sequentially with the scrambler output bits to randomize the bits prior to modulation. The scrambled slot buffer corresponding to slot index i is denoted as $SB(i)$, where $i \in \{0, 1, \dots, 7\}$. The scrambling sequence used for any slot buffer depends on the OFDM symbol index and the slot index.

[00185] The scrambling bit sequence shall be equivalent to one generated with a 20-tap linear feedback shift register (LFSR) with the generator sequence $h(D) = D^{20} + D^{17} + 1$, as shown in FIG. 16. The transmitter shall use a single LFSR for all transmissions.

[00186] At the start of every OFDM symbol, the LFSR shall be initialized to the state $[d_3 d_2 d_1 d_0 c_3 c_2 c_1 c_0 b_0 a_{10} a_9 a_8 a_7 a_6 a_5 a_4 a_3 a_2 a_1 a_0]$, which depends on the channel type (the TDM Pilot or the Wide-area or the Local-area Channel), and the OFDM symbol index in a superframe.

[00187] Bits ' $d_3 d_2 d_1 d_0$ ' shall be set as follows. For all the Wide-area channels (the WIC, the WTPC, the Wide-area OIS and the Wide-area Data Channel), the Local-area

channels (the LIC, the LTPC, the Local-area OIS and the Local-area Data Channel) and the TDM Pilot 2 Channel and the 2 Reserved OFDM symbols when the PPC is absent, these bits shall be set to the 4-bit Wide-area Differentiator (WID).

[00188] Bits 'c₃c₂c₁c₀' shall be set as follows: for the TDM Pilot 2 Channel, the Wide-area OIS Channel, the Wide-area Data Channel, the WTPC and the WIC these bits shall be set to '0000'; for the Local-area OIS Channel, the LTPC, the LIC and the Local-area Data Channel and the 2 Reserved OFDM symbols when the PPC is absent, these bits shall be set to the 4-bit Local-area Differentiator (LID). Bit b₀ is a reserved bit and shall be set to '1'. Bits a₁₀ through a₀ shall correspond to the OFDM symbol index number in a superframe, which ranges from 0 through 1199.

[00189] The scrambling sequence for each slot shall be generated by a modulo-2 inner product of the 20-bit state vector of the sequence generator and a 20-bit mask associated with that slot index as specified in Table 7 below.

Slots Index	m ₁₉	m ₁₈	m ₁₇	m ₁₆	m ₁₅	m ₁₄	m ₁₃	m ₁₂	m ₁₁	m ₁₀	m ₉	m ₈	m ₇	m ₆	m ₅	m ₄	m ₃	m ₂	m ₁	m ₀
0	0	0	1	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1	0
1	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0
2	1	0	0	1	0	0	0	0	1	0	0	0	0	1	1	0	0	0	1	1
3	0	0	1	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0
4	1	1	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0
5	1	0	0	1	0	0	0	0	1	0	0	0	0	1	0	0	0	0	1	0
6	0	1	1	0	0	0	1	0	0	0	0	1	0	0	0	0	1	1	0	0
7	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 7. Mask Associated with Different Slots

[00190] The shift register shall be reloaded with a new state [d₃d₂d₁d₀c₃c₂c₁c₀b₀a₁₀a₉a₈a₇ a₆a₅a₄a₃a₂a₁a₀] for each slot at the start of every OFDM symbol.

Modulation Symbol Mapping

[00191] Each group of two consecutive bits from the ith scrambled slot buffer, SB(i, 2k) and SB(i, 2k + 1), i=3, k = 0,1,...499, which are labeled as s₀ and s₁, respectively, shall be mapped into a complex modulation symbol MS= (mI, mQ) as specified in

Table 6 with $D = 2$. It is noted that the value of D is chosen to keep the OFDM symbol energy constant, since only 500 of the 4000 available sub-carriers are used. FIG. 13 shows the signal constellation for the QPSK modulation.

Slot to Interlace Mapping

[00192] The mapping of slots to interlaces for the WIC OFDM symbol shall be as specified as discussed later in this specification.

Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00193] The 500 modulation symbols in the allocated slot shall be sequentially assigned to 500 interlace sub-carriers as follows: the i^{th} complex modulation symbol (where $i \in \{0, 1, \dots, 499\}$) shall be mapped to the i^{th} sub-carrier of that interlace.

OFDM Common Operation

[00194] The modulated WIC sub-carriers shall undergo common operations as specified later in this specification.

Local-area Identification Channel (LIC)

[00195] The Local-area Identification Channel (LIC) shall span one OFDM symbol. It shall be transmitted at OFDM symbol index 2 in a superframe. It follows the WIC channel OFDM symbol. This is an overhead channel that is used for conveying the Local-area Differentiator information to FLO receivers. All Local-area transmit waveforms shall be scrambled using a 4-bit Local-area Differentiator, in conjunction with the Wide-area Differentiator, corresponding to that area.

[00196] For the LIC OFDM symbol in a superframe only a single slot shall be allocated. The allocated slot shall use a 1000-bit fixed pattern as input. These bits shall be set to zero. These bits shall be processed according to the steps illustrated in FIG. 14. No processing shall be performed for the un-allocated slots.

Slot Allocation

[00197] The LIC shall be allocated the slot with index 5. The allocated and un-allocated slots in the LIC OFDM symbol are illustrated in FIG. 17. The slot index chosen is the one that maps to interlace 0 for OFDM symbol index 2.

Filling of Slot Buffer

[00198] The buffer for the allocated slot shall be completely filled with a fixed pattern consisting of 1000 bits, with each bit set to '0'. The buffers for the un-allocated slots shall be left empty.

Slot Scrambling

[00199] The bits of the LIC slot buffer shall be scrambled as specified in 0. The scrambled slot buffer is denoted by SB.

Modulation Symbol Mapping

[00200] Each group of two consecutive bits from the i^{th} scrambled slot buffer, $SB(i, 2k)$ and $SB(i, 2k + 1)$, $i=5$, $k = 0,1,...499$, which are labeled as s_0 and s_1 , respectively, shall be mapped into a complex modulation symbol $MS = (mI, mQ)$ as specified in Table 6 with $D = 2$. The value of D is chosen to keep the OFDM symbol energy constant, since only 500 of the 4000 available sub-carriers are used. FIG. 13 shows the signal constellation for the QPSK modulation.

Slot to Interlace Mapping

[00201] The mapping of slots to interlaces for the LIC OFDM symbol shall be as specified as discussed later.

Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00202] The 500 modulation symbols in the allocated slot shall be sequentially assigned to 500 interlace sub-carriers as follows: the i^{th} complex modulation symbol (where $i \in \{0,1,...499\}$) shall be mapped to the i^{th} sub-carrier of that interlace.

OFDM Common Operation

[00203] The modulated LIC sub-carriers shall undergo common operations as specified as discussed later.

TDM Pilot 2 Channel

[00204] The TDM Pilot 2 Channel shall span one OFDM symbol. It shall be transmitted at OFDM symbol index 3 in a superframe. It follows the LIC OFDM symbol. It may be used for fine OFDM symbol timing corrections in the FLO receivers.

[00205] For the TDM Pilot 2 OFDM symbol in each superframe only 4 slots shall be allocated. Each allocated slot shall use as input a 1000-bit fixed pattern, with each bit

set to zero. These bits shall be processed according to the steps illustrated in FIG.14. No processing shall be performed for the un-allocated slots.

[00206] In FIG. 14 the mapping of slots to interlaces ensures that the allocated slots are mapped into interlaces 0, 2, 4, and 6. Therefore, the TDM Pilot 2 OFDM symbol is comprised of 2000 non-zero sub-carriers which are uniformly spaced among the Active sub-carriers (see [00138]). The i^{th} TDM Pilot 2 sub-carrier shall correspond to the sub-carrier index j defined as follows:

$$j = \begin{cases} 48 + (i) \times 2, \forall i \in \{0, 1..999\} \\ 48 + (i+1) \times 2, \forall i \in \{1000, \dots, 1999\} \end{cases}$$

[00207] Note that the TDM Pilot 2 Channel does not use the sub-carrier with index 2048.

Slot Allocation

[00208] For the TDM Pilot 2 OFDM symbol, the allocated slots shall have indices 0, 1, 2, and 7.

[00209] The allocated and un-allocated slots in the TDM Pilot 2 OFDM symbol are illustrated in FIG. 18.

Filling of Slot Buffer

[00210] The buffer for each allocated slot shall be completely filled with a fixed pattern consisting of 1000 bits, with each bit set to '0'. The buffers for the un-allocated slots shall be left empty.

Slot Scrambling

[00211] The bits of the TDM Pilot 2 Channel slot buffers shall be scrambled as specified as discussed above. The scrambled slot buffer is denoted by SB.

Modulation Symbol Mapping

[00212] Each group of two adjacent bits from the i^{th} scrambled slot buffer, $SB(i, 2k)$ and $SB(i, 2k + 1)$, $i=0, 1, 2, 7$, $k = 0, 1, \dots, 499$, which are labeled as s_0 and s_1 , respectively, shall be mapped into a complex modulation symbol $MS = (mI, mQ)$ as specified in Table 6 with $D = 1$. The value of D is chosen to keep the OFDM symbol energy constant, since only 2000 of the 4000 available sub-carriers are used. FIG. 13 shows the signal constellation for the QPSK modulation.

Slot to Interlace Mapping

[00213] The mapping of slots to interlaces for the TDM Pilot 2 Channel OFDM symbol shall be as specified herein.

Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00214] The 500 modulation symbols in an allocated slot shall be sequentially assigned to 500 interlace sub-carriers as follows: the i^{th} complex modulation symbol (where $i \in \{0, 1, \dots, 499\}$) shall be mapped to the i^{th} sub-carrier of that interlace.

OFDM Common Operation

[00215] The modulated TDM Pilot 2 Channel sub-carriers shall undergo common operations as specified herein.

Transition Pilot Channel (TPC)

[00216] The Transition Pilot Channel consists of 2 sub-channels: the Wide-area Transition Pilot Channel (WTPC) and the Local-area Transition Pilot Channel (LTPC). The TPC flanking the Wide-area OIS and the Wide-area Data channel is called the WTPC. The TPC flanking the Local-area OIS and the Local-area Data Channel is called the LTPC. The WTPC spans 1 OFDM symbol on either side of every Wide-area channel transmission with the exception of the WIC (the Wide-area Data and the Wide-area OIS Channel) in a superframe. The LTPC spans 1 OFDM symbol on either side of every Local-area Channel transmission with the exception of the LIC (the Local-area Data and the Local-area OIS Channel). The purpose of the TPC OFDM symbol is two-fold: to allow channel estimation at the boundary between the Local-area and the Wide-area channels and to facilitate timing synchronization for the first Wide-area (or Local-area) MLC in each frame. The TPC spans 20 OFDM symbols in a superframe, which are equally divided between the WTPC and the LTPC as illustrated in FIG. 10. There are nine instances where the LTPC and the WTPC transmissions occur right next to each other and two instances where only one of these channels is transmitted. Only the WTPC is transmitted after the TDM Pilot 2 Channel, and only the LTPC is transmitted prior to the Positioning Pilot Channel (PPC)/Reserved OFDM symbols.

[00217] It is assumed that P is the number of OFDM symbols in the PPC or the number of Reserved OFDM symbols in the case where the PPC is absent in a superframe, W is

the number of OFDM symbols associated with the Wide-area Data Channel in a frame, L is the number of OFDM symbols associated with the Local-area Data Channel in a frame, and F be the number of OFDM symbols in a frame.

[00218] The values of P shall be 2, 6, 10, or 14. The number of Data Channel OFDM symbols in a frame shall be $F - 4$. The exact locations of the TPC OFDM symbols in a superframe shall be as specified in Table 8 below.

Transition Pilot Channel	Index for the WTPC OFDM Symbol	Index for the LTPC OFDM Symbol
TDM Pilot 2 Channel $\rightarrow$ Wide-area OIS Channel	4	---
Wide-area OIS Channel $\rightarrow$ Local-area OIS Channel	10	11
Local-area OIS Channel $\rightarrow$ Wide-area Data Channel	18	17
Wide-area Data Channel $\rightarrow$ Local-area Data Channel	$19 + W + F \times i$, $\{i = 0, 1, 2, 3\}$	$20 + W + F \times i$, $\{i = 0, 1, 2, 3\}$
Local-area Data Channel $\rightarrow$ Wide-area Data Channel	$18 + F \times i$, $\{i = 1, 2, 3\}$	$17 + F \times i$, $\{i = 1, 2, 3\}$
Local-area Data Channel $\rightarrow$ PPC/Reserved Symbols	---	1199-P

Table 8 - TPC Location Indices in a Superframe

[00219] All slots in the TPC OFDM symbols use as input a 1000-bit fixed pattern, with each bit set to zero. These bits shall be processed according to the steps illustrated in FIG. 14.

Slot Allocation

[00220] The TPC OFDM symbol shall be allocated all 8 slots with indices 0 through 7.

Filling of Slot Buffer

[00221] The buffer for each allocated slot shall be completely filled with a fixed pattern consisting of 1000 bits, with each bit set to '0'.

Slot Scrambling

[00222] The bits of each allocated TPC slot buffer shall be scrambled as specified previously. The scrambled slot buffer is denoted by SB.

Modulation Symbol Mapping

[00223] Each group of two consecutive bits from the i^{th} scrambled slot buffer, $SB(i, 2k)$ and $SB(i, 2k + 1)$, $i=0,1,2,\dots,7$, $k = 0,1,\dots,499$, which are labeled as s_0 and s_1 respectively, shall be mapped into a complex modulation symbol $MS = (mI, mQ)$ as specified in Table 6 with $D = \frac{1}{\sqrt{2}}$. FIG. 13 shows the signal constellation for the QPSK modulation.

Slot to Interlace Mapping

[00224] The mapping of slots to interlaces for the TPC OFDM symbol shall be as specified herein.

Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00225] The 500 modulation symbols in each allocated slot shall be sequentially assigned to 500 interlace sub-carriers as follows: the i^{th} complex modulation symbol (where $i \in \{0,1,\dots,499\}$) shall be mapped to the i^{th} sub-carrier of that interlace.

OFDM Common Operation

[00226] The modulated TPC sub-carriers shall undergo common operations as specified in herein.

Positioning Pilot Channel /Reserved Symbols

[00227] The Positioning Pilot Channel (PPC) may appear at the end of a superframe. When present it has a variable duration of 6, 10, or 14 OFDM symbols. When the PPC is absent, there are two Reserved OFDM symbols at the end of the superframe. The presence or absence of the PPC and its duration are signaled over the OIS Channel.

Positioning Pilot Channel

[00228] The PPC structure including the information transmitted and the waveform generation is TBD.

[00229] The FLO device may use the PPC either autonomously or in conjunction with the GPS signal to determine its geographical location.

Reserved OFDM Symbols

[00230] When the PPC is absent, there are two Reserved OFDM symbols at the end of the superframe.

[00231] All slots in the Reserved OFDM Symbols use as input a 1000-bit fixed pattern, with each bit set to zero. These bits shall be processed according to the steps illustrated in FIG. 14

Slot Allocation

[00232] The Reserved OFDM symbol shall be allocated all 8 slots with indices 0 through 7.

Filling of Slot Buffer

[00233] The buffer for each allocated slot shall be completely filled with a fixed pattern consisting of 1000 bits, with each bit set to '0'.

Slot Scrambling

[00234] The bits of each allocated Reserved OFDM symbol slot buffer shall be scrambled as specified in 0. The scrambled slot buffer is denoted by SB.

Modulation Symbol Mapping

[00235] Each group of two consecutive bits from the i^{th} scrambled slot buffer, $SB(i, 2k)$ and $SB(i, 2k + 1)$, $i=0, 1, 2, \dots, 7$, $k = 0, 1, \dots, 499$, which are labeled as s_0 and s_1 , respectively, shall be mapped into a complex modulation symbol $MS = (mI, mQ)$ as specified in Table 6 with $D = 1/\sqrt{2}$. FIG. 13 shows the signal constellation for the QPSK modulation.

Slot to Interlace Mapping

[00236] The mapping of slots to interlaces for the Reserved OFDM symbols shall be as specified herein.

Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00237] The 500 modulation symbols in each allocated slot shall be sequentially assigned to 500 interlace sub-carriers as follows: the i^{th} complex modulation symbol (where $i \in \{0, 1, \dots, 499\}$) shall be mapped to the i^{th} sub-carrier of that interlace.

OFDM Common Operation

[00238] The modulated Reserved OFDM Symbol sub-carriers shall undergo common operations as specified herein.

Wide-area OIS Channel

[00239] This channel is used to convey overhead information about the active MLC's associated with the Wide-area Data Channel, such as their scheduled transmission times and slot allocations, in the current superframe. The Wide-area OIS Channel spans 5 OFDM symbol intervals in each superframe (see FIG. 10).

[00240] The Physical layer packet for the Wide-area OIS Channel shall be processed according to the steps illustrated in FIG. 19.

Encoding

[00241] The Wide-area OIS Channel Physical layer packets shall be encoded with code rate $R = 1/5$. The encoder shall discard the 6-bit TAIL field of the incoming Physical layer packet and encode the remaining bits with a parallel turbo encoder as specified herein. The turbo encoder shall add an internally generated tail of $6/R (=30)$ output code bits, so that the total number of turbo encoded bits at the output is $1/R$ times the number of bits in the input Physical layer packet.

[00242] FIG. 20 illustrates the encoding scheme for the Wide-area OIS Channel. The Wide-area OIS Channel encoder parameters shall be as specified in Table 9 below.

Bits	Turbo Encoder Input Bits N_{turbo}	Code Rate	Turbo Encoder Output bits
1000	994	1/5	5000

Table 9 -Parameters of the Wide-area/Local-area OIS Channel Encoder

Turbo Encoder

[00243] The turbo encoder employs two systematic, recursive, convolutional encoders connected in parallel, with an interleaver, the turbo interleaver, preceding the second recursive convolutional encoder. The two recursive convolutional codes are called the constituent codes of the turbo code. The outputs of the constituent encoders are punctured and repeated to achieve the desired number of turbo encoded output bits.

[00244] A common constituent code shall be used for turbo codes of rates 1/5, 1/3, 1/2, and 2/3. The transfer function for the constituent code shall be as follows:

$$G(D) = \begin{bmatrix} 1 & \frac{n_0(D)}{d(D)} & \frac{n_1(D)}{d(D)} \end{bmatrix}$$

[00245] where $d(D) = 1 + D^2 + D^3$, $n_0(D) = 1 + D + D^3$, and $n_1(D) = 1 + D + D^2 + D^3$.

[00246] The turbo encoder shall generate an output symbol sequence that is identical to the one generated by the encoder shown in FIG. 20. Initially, the states of the constituent encoder's registers in this figure are set to zero. Then, the constituent encoders are clocked with the switches in the position noted.

[00247] The encoded data output bits are generated by clocking the constituent encoders N_{turbo} times with the switches in the up positions and puncturing the output as specified in Table 10, which is shown below. Within a puncturing pattern, a '0' means that the bit shall be deleted and a '1' means that the bit shall be passed. The constituent encoder outputs for each bit period shall be passed in the sequence X, Y₀, Y₁, X', Y'₀, Y'₁ with the X output first. Bit repetition is not used in generating the encoded data output bits.

[00248] The constituent encoder output symbol puncturing for the tail period shall be as specified in Table 11, shown below. Within a puncturing pattern, a '0' means that the symbol shall be deleted and a '1' means that a symbol shall be passed.

[00249] For rate 1/5 turbo codes, the tail output code bits for each of the first three tail periods shall be punctured and repeated to achieve the sequence XXY₀Y₁Y₁, and the tail output code bits for each of the last three tail bit periods shall be punctured and repeated to achieve the sequence X'X'Y'₀Y'₁Y'₁.

	Code Rate
Output	1/5
X	1
Y_0	1
Y_1	1
$X^\square$	0
$Y^\square_0$	1
$Y^\square_1$	1

Table 10 - Puncturing Patterns for the Data Bit Periods for the OIS Channel

[00250] It is noted that in Table 10 above, the puncturing table is to be read from top to bottom.

	Code Rate
Output	1/5
X	111 000
Y_0	111 000
Y_1	111 000
$X^\square$	000 111
$Y^\square_0$	000 111
$Y^\square_1$	000 111

Table 11 -Puncturing Patterns for the Tail Bit Periods for the OIS Channel

[00251] It is noted that in Table 11, for rate-1/5 turbo codes, the puncturing table is to be read first from top to bottom repeating X, $X^\square$, Y_1 , and $Y^\square_1$ and then from left to right.

Turbo Interleaver

[00252] The turbo interleaver, which is part of the turbo encoder, shall block interleave the turbo encoder input data that is fed to the Constituent Encoder 2.

[00253] The turbo interleaver shall be functionally equivalent to an approach where the entire sequence of turbo interleaver input bits are written sequentially into an array at a

sequence of addresses and then the entire sequence is read out from a sequence of addresses that are defined by the procedure described below.

[00254] Let the sequence of input addresses be from 0 to $N_{\text{turbo}} - 1$. Then, the sequence of interleaver output addresses shall be equivalent to those generated by the procedure illustrated in FIG. 22 and described below. It is noted that this procedure is equivalent to one where the counter values are written into a 25-row by $2n$ column array by rows, the rows are shuffled according to a bit-reversal rule, the elements within each row are permuted according to a row-specific linear congruential sequence, and tentative output addresses are read out by column. The linear congruential sequence rule is $x(i + 1) = (x(i) + c) \bmod 2n$, where $x(0) = c$ and c is a row-specific value from a table lookup.

[00255] Concerning the procedure in FIG. 22, the process includes determining the turbo interleaver parameter, n , where n is the smallest integer such that $N_{\text{turbo}} \leq 2n+5$. Table 12 shown below gives this parameter for the 1000-bit physical layer packet. The process also includes initializing an $(n + 5)$ -bit counter to 0 and extracting the n most significant bits (MSBs) from the counter and adding one to form a new value. Then, discard all except the n least significant bits (LSBs) of this value. The process further includes obtaining the n -bit output of the table lookup defined in Table 13 shown below with a read address equal to the five LSBs of the counter. Note that this table depends on the value of n .

[00256] The process further includes multiplying the values obtained in the previous steps of extracting and obtaining, and then discarding all except the n LSBs. Next bit-reverse the five LSBs of the counter is performed. A tentative output address is then formed that has its MSBs equal to the value obtained in the bit-reverse step and its LSBs equal to the value obtained in the multiplying step.

[00257] Next, the process includes accepting the tentative output address as an output address if it is less than N_{turbo} ; otherwise, it is discarded. Finally, the counter is incremented and the steps after the initialization step are repeated until all N_{turbo} interleaver output addresses are obtained.

Physical Layer Packet Size	Turbo Interleaver Block Size N_{turbo}	Turbo Interleaver Parameter n
1,000	994	5

Table 13 - Turbo Interleaver Lookup Table Definition

Bit Interleaving

[00258] For the OIS Channel and the Data Channel, the bit interleaving is a form of block interleaving. The code bits of a turbo encoded packet are interleaved in such a pattern that adjacent code bits are mapped into different constellation symbols.

[00259] The Bit Interleaver shall reorder the turbo encoded bits as per the following procedure:

- a. For N bits to be interleaved, the bit interleaver matrix M shall be a 4 columns by $N/4$ rows block interleaver. The N input bits shall be written into the interleaving

array column-by-column sequentially. Label the rows of the matrix M by index j , where $j = 0$ through $N/4 - 1$ and row 0 is the first row.

b. For every row j , with even index ($j \bmod 2 = 0$), the elements in the 2nd and the 3rd column shall be interchanged.

c. For every row with odd index ($j \bmod 2 \neq 0$), the elements in the 1st and the 4th column shall be interchanged.

d. Denote the resulting matrix by $\overline{M}$. The contents of $\overline{M}$ shall be read out row-wise, from left to right.

[00260] FIG. 23 illustrates the output of the bit-interleaver for the hypothetical case of $N = 20$.

Data Slot Allocation

[00261] For the Wide-area OIS Channel, 7 data slots shall be allocated per OFDM symbol for the transmission of OIS Channel turbo encoded packets. The Wide-area OIS Channel shall use transmit mode 5. Therefore, it requires 5 data slots to accommodate the content of a single turbo encoded packet. Some Wide-area OIS Channel turbo encoded packets may span two consecutive OFDM symbols. The data slot allocations are made at the MAC layer.

Filling of Data Slot Buffer

[00262] The bit-interleaved code bits of a Wide-area OIS Channel turbo encoded packet shall be written sequentially into 5 consecutive data slot buffers in either one or two consecutive OFDM symbols as illustrated in FIG. 24. These data slot buffers correspond to slot indices 1 through 7. The data slot buffer size shall be 1000 bits. It is noted that the data slot buffer size is 1000 bits for QPSK and 2000 bits for 16-QAM and layered modulation. The 7 Wide-area OIS Channel turbo encoded packets (TEP) shall occupy consecutive slots over 5 consecutive OFDM symbols in the Wide-area OIS Channel (see FIG. 10).

Slot Scrambling

[00263] The bits of each allocated slot buffer shall be scrambled as specified in Table . The scrambled slot buffer is denoted by SB.

Mapping of Bits to Modulation Symbols

[00264] Each group of two consecutive bits from the i^{th} scrambled slot buffer, $SB(i, 2k)$ and $SB(2k + 1)$, $i = 1, 2, \dots, 7$, $k = 0, 1, \dots, 499$, which are labeled as s_0 and s_1 , respectively, shall be mapped into a complex modulation symbol $MS = (mI, mQ)$ as specified in Table 6 with $D = 1/\sqrt{2}$. FIG. 13 shows the signal constellation for the QPSK modulation.

Slot to Interlace Mapping

[00265] The mapping of slots to interlaces for the Wide-area OIS Channel OFDM symbols shall be as specified herein.

Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00266] The 500 modulation symbols in each allocated slot shall be sequentially assigned to 500 interlace sub-carriers as per the following procedure:

- a. Create an empty Sub-carrier Index Vector (SCIV);
- b. Let i be an index variable in the range ($i \in \{0, 511\}$). Initialize i to 0;
- c. Represent i by its 9-bit value i_b ;
- d. Bit reverse i_b and denote the resulting value as i_{br} . If $i_{br} < 500$, then append i_{br} to the SCIV;
- e. If $i < 511$, then increment i by 1 and go to step c; and
- f. Map the symbol with index, j ($j \in \{0, 499\}$), in a data slot to the interlace sub-carrier with index SCIV [j] assigned to that data slot.

[00267] It is noted that index SCIV needs to be computed only once and can be used for all data slots.

OFDM Common Operation

[00268] The modulated Wide-area OIS Channel sub-carriers shall undergo common operations as specified herein.

Local-area OIS Channel

[00269] This channel is used to convey overhead information about the active MLCs associated with the Local-area Data Channel, such as their scheduled transmission times

and slot allocations, in the current superframe. The Local-area OIS channel spans 5 OFDM symbol intervals in each superframe (see FIG. 10).

[00270] The Physical layer packet for the Local-area OIS Channel shall be processed according to the steps illustrated in FIG. 14

Encoding

[00271] The Local-area OIS Channel Physical layer packets shall be encoded with code rate $R = 1/5$. The encoding procedure shall be identical to that for the Wide-area OIS Channel Physical layer packets as specified herein.

Bit Interleaving

[00272] The Local-area OIS Channel turbo encoded packet shall be bit interleaved as specified herein.

Data Slot Allocation

[00273] For the Local-area OIS Channel, 7 data slots shall be allocated per OFDM symbol for the transmission of turbo encoded packets. The Local-area OIS Channel shall use transmit mode 5. Therefore, it requires 5 data slots to accommodate the content of a single turbo encoded packet. Some Local-area OIS turbo-packets may span two consecutive OFDM symbols. The data slot allocations are made at the MAC layer.

Filling of Data Slot Buffers

[00274] The bit-interleaved code bits of a Local-area OIS Channel turbo encoded packet shall be written sequentially into 5 consecutive data slot buffers in either one or two consecutive OFDM symbols as illustrated in FIG. 25. These data slot buffers correspond to slot indices 1 through 7. The data slot buffer size shall be 1000 bits. The 7 Local-area OIS Channel turbo encoded packets (TEP) shall occupy consecutive slots over 5 consecutive OFDM symbols in the Local-area OIS Channel (see FIG. 25).

Slot Scrambling

[00275] The bits of each allocated slot buffer shall be scrambled as specified in 0. The scrambled slot buffer is denoted by SB.

Mapping of bits to Modulation Symbols

[00276] Each group of two consecutive bits from the i^{th} scrambled slot buffer, $SB(i, 2k)$ and $SB(i, 2k + 1)$, $i=1,2,\dots,7$, $k = 0,1,\dots,499$, which are labeled as s_0 and s_1 respectively, shall be mapped into a complex modulation symbol $MS = (mI, mQ)$ as specified in Table 6 with $D = 1/\sqrt{2}$. FIG. 13 shows the signal constellation for the QPSK modulation.

Slot to Interlace Mapping

[00277] The mapping of slots to interlaces for the Local-area OIS Channel OFDM symbols shall be as specified herein.

Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00278] This procedure shall be identical to that for the Wide-area OIS Channel as specified herein.

OFDM Common Operation

[00279] The modulated Local-area OIS Channel sub-carriers shall undergo common operations as specified herein.

Wide-area FDM Pilot Channel

[00280] The Wide-area FDM Pilot Channel is transmitted in conjunction with the Wide-area Data Channel or the Wide-area OIS Channel. The Wide-area FDM Pilot Channel carries a fixed bit pattern that may be used for Wide-area Channel estimation and other functions by the FLO device.

[00281] For the Wide-area FDM Pilot Channel a single slot shall be allocated during every OFDM symbol that carries either the Wide-area Data Channel or the Wide-area OIS Channel.

[00282] The allocated slot shall use a 1000-bit fixed pattern as input. These bits shall be set to zero. These bits shall be processed according to the steps illustrated in FIG. 14.

Slot Allocation

[00283] The Wide-area FDM Pilot Channel shall be allocated the slot with index 0 during every OFDM symbol that carries either the Wide-area Data Channel or the Wide-area OIS Channel.

Filling of Slot Buffer

[00284] The buffer for the slot allocated to the Wide-area FDM Pilot Channel shall be completely filled with a fixed pattern consisting of 1000-bits, with each bit set to '0'.

Slot Scrambling

[00285] The bits of the Wide-area FDM Pilot Channel slot buffer shall be scrambled as specified herein. The scrambled slot buffer is denoted by SB.

[00286] Modulation Symbol Mapping

[00287] Each group of two consecutive bits of the i^{th} scrambled slot buffer, $SB(i, 2k)$ and $SB(i, 2k+1)$, $i = 0$, $k = 0, 1, \dots, 499$, which are labeled as s_0 and s_1 , respectively, shall be mapped into a complex modulation symbol $MS = (mI, mQ)$ as specified in Table 6 with $D = 1/\sqrt{2}$. FIG. 13 shows the signal constellation for the QPSK modulation.

Slot to Interlace Mapping

[00288] The mapping of the Wide-area FDM Pilot Channel slots to interlaces shall be as specified herein.

Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00289] The 500 modulation symbols in the allocated slot shall be sequentially assigned to 500 interlace sub-carriers as follows: the i^{th} complex modulation symbol (where $i \in \{0, 1, \dots, 499\}$) shall be mapped to the i^{th} sub-carrier of that interlace.

OFDM Common Operation

[00290] The modulated Wide-area FDM Pilot Channel sub-carriers shall undergo common operations as specified herein.

Local-area FDM Pilot Channel

[00291] The Local-area FDM Pilot Channel is transmitted in conjunction with the Local-area Data Channel or the Local-area OIS Channel. The Local-area FDM Pilot Channel carries a fixed bit pattern that may be used for Local-area channel estimation and other functions by the FLO device.

[00292] For the Local-area FDM Pilot Channel a single slot shall be allocated during every OFDM symbol that carries either the Local-area Data Channel or the Local-area OIS Channel.

[00293] The allocated slot shall use a 1000-bit fixed pattern as input. These bits shall be set to zero. These bits shall be processed according to the steps illustrated in FIG. 14.

Slot Allocation

[00294] The Local-area FDM Pilot Channel shall be allocated the slot with index 0 during every OFDM symbol that carries either the Local-area Data Channel or the Local-area OIS Channel.

Filling of Pilot Slot Buffer

[00295] The buffer for the slot allocated to the Local-area FDM Pilot Channel shall be completely filled with a fixed pattern consisting of 1000-bits with each bit set to '0'.

Slot Buffer Scrambling

[00296] The bits of the Local-area FDM Pilot slot buffer shall be scrambled as specified in 0. The scrambled slot buffer is denoted by SB.

Modulation Symbols Mapping

[00297] Each group of two consecutive bits of the i^{th} scrambled slot buffer, $SB(i, 2k)$ and $SB(i, 2k+1)$, $i=0$, $k=0,1,\dots,499$ which are labeled as s_0 and s_1 , respectively, shall be mapped into a complex modulation symbol $MS=(mI, mQ)$ as specified in Table 6 with $D=1/\sqrt{2}$. FIG. 13 shows the signal constellation for the QPSK modulation.

Slot to Interlace Mapping

[00298] The mapping of the Wide-area FDM Pilot Channel slots to interlaces shall be as specified herein.

Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00299] The 500 modulation symbols in the allocated slot shall be sequentially assigned to 500 interlace sub-carriers as follows: the i^{th} complex modulation symbol (where $i \in \{0,1,\dots,499\}$) shall be mapped to the i^{th} sub-carrier of that interlace.

OFDM Common Operation

[00300] The modulated Local-area FDM Pilot Channel sub-carriers shall undergo common operations as specified herein.

Wide-area Data Channel

[00301] The Wide-area Data Channel is used to carry Physical layer packets meant for Wide-area multicast. The Physical layer packets for the Wide-area Data Channel can be associated with any one of the active MLCs transmitted in the Wide-area.

Wide-area Data Channel Processing for Allocated Slots

[00302] The Physical layer packet for the Wide-area Data Channel shall be processed according to the steps illustrated in FIG. 26.

[00303] For regular modulation (QPSK and 16-QAM), the Physical layer packet is turbo-encoded and bit interleaved before being stored in the Data slot buffer(s). For layered modulation, the base-component Physical layer packet and the enhancement-component Physical layer packet are turbo-encoded and bit interleaved independently before being multiplexed in to the Data slot buffer(s).

Encoding

[00304] The Wide-area Data Channel Physical layer packets shall be encoded with code rate $R = 1/2$, $1/3$, or $2/3$. The encoder shall discard the 6-bit TAIL field of the incoming Physical layer packet and encode the remaining bits with a parallel turbo encoder as specified herein. The turbo encoder shall add an internally generated tail of $6/R$ ($=12$, 18 or 9) output code bits, so that the total number of turbo encoded bits at the output is $1/R$ times the number of bits in the input Physical layer packet.

[00305] FIG. 27 illustrates the encoding scheme for the Wide-area Data Channel. The Wide-area Data Channel encoder parameters shall be as specified in Table 14 below.

Bits	Turbo Encoder Input Bits N_{turbo}	Code Rate	Turbo Encoder Output bits
1000	994	$1/2$	2000
1000	994	$1/3$	3000
1000	994	$2/3$	1500

Table 14 - Parameters of the Data Channel Encoder

Turbo Encoder

[00306] The turbo encoder used for Wide-area Data Channel Physical layer packets shall be as specified herein.

[00307] The encoded data output bits are generated by clocking the constituent encoders N_{turbo} times with the switches in the up positions and puncturing the output as specified in Table 15 shown below. Within a puncturing pattern, a '0' means that the bit shall be deleted and a '1' means that the bit shall be passed. The constituent encoder outputs for each bit period shall be passed in the sequence X, Y0, Y1, X□, Y□0, Y□1 with the X output first. Bit repetition is not used in generating the encoded data output symbols.

[00308] The constituent encoder output symbol puncturing for the tail period shall be as specified in Table 16 shown below. Within a puncturing pattern, a '0' means that the symbol shall be deleted and a '1' means that a symbol shall be passed.

[00309] For rate 1/2 turbo codes, the tail output code bits for each of the first three tail bit periods shall be XY₀, and the tail output code bits for each of the last three tail bit periods shall be X□Y□0.

[00310] For rate 1/3 turbo codes, the tail output code bits for each of the first three tail bit periods shall be XXY₀, and the tail output code bits for each of the last three tail bit periods shall be X□ X□Y□0.

[00311] For rate 2/3 turbo codes, the tail output code bits for the first three tail bit periods shall be XY₀, X and XY₀ respectively. The tail output code bits for the last three tail bit periods shall be X□X□Y□0 and X□, respectively

Output	Code Rate		
	1/2	1/3	2/3
X	11	11	1111
Y ₀	10	11	1000
Y ₁	00	00	0000
X _□	00	00	0000
Y _{□0}	01	11	0001
Y _{□1}	00	00	0000

Table 15 - Puncturing Patterns for the Data Bit Periods

[00312] It is noted that in Table 15 above, the puncturing table is to be read from top to bottom.

Output	Code Rate		
	1/2	1/3	2/3
X	111 000	111 000	111 000
Y ₀	111 000	111 000	101 000
Y ₁	000 000	000 000	000 000
X _□	000 111	000 111	000 111
Y _{□0}	000 111	000 111	000 010
Y _{□1}	000 000	000 000	000 000

Table 16 - Puncturing Patterns for the Tail Bit Periods

[00313] It is noted concerning Table 16 above, for rate-1/2 turbo codes, the puncturing table is to be read first from top to bottom and then from left to right. For Rate 1/3 turbo code, the puncturing table is to be read from top to bottom repeating X and X', and then from left to right. For rate-2/3 turbo codes, the puncturing table is to be read first from top to bottom and then from left to right.

Turbo Interleaver

[00314] The turbo interleaver for the Wide-area Data Channel shall be as specified herein.

Bit Interleaving

[00315] The Wide-area Data Channel turbo encoded packets shall be bit interleaved as specified herein.

Data Slot Allocation

[00316] For the Wide-area Data Channel, up to 7 data slots may be allocated per OFDM symbol for the transmission of multiple turbo encoded packets associated with one or more MLCs. For certain modes (2, 4, 8 and 11, see Table 5 above) a turbo encoded packet occupies a fraction of a slot. However, slots are allocated to MLCs in a manner that avoids multiple MLCs sharing slots within the same OFDM symbol.

Filling of Data Slot Buffers

[00317] The bit-interleaved code bits of a Wide-area Data Channel turbo encoded packet shall be written into one or more data slot buffers. These data slot buffers correspond to slot indices 1 through 7. The data slot buffer size shall be 1000 bits for QPSK and 2000 bits for 16-QAM and layered modulation. For QPSK and 16-QAM modulation, the bit-interleaved code bits shall be sequentially written into the slot buffer(s). For layered modulation, the bit-interleaved code bits corresponding to the base and the enhancement components shall be interleaved as illustrated in FIG. 28, prior to filling the slot buffer(s).

[00318] FIG. 29 illustrates the case where a single turbo encoded packet spans three data slot buffers.

[00319] FIG. 30 illustrates the case where a base component turbo encoded packet with code rate $1/3$ is multiplexed with an enhancement component turbo packet (with the same code rate) to occupy 3 data slot buffers.

[00320] FIG. 31 illustrates the case where a Data Channel turbo encoded packet occupies a fraction of a data slot and four turbo encoded packets are required to fill up an integer number of data slots.

[00321] The three slots in the FIG. 31 may span one OFDM symbol or multiple consecutive OFDM symbols. In either case, the data slot allocation over an OFDM symbol for an MLC shall have consecutive slot indices.

[00322] FIG. 32 illustrates a snapshot of slot allocations to five different MLCs over three consecutive OFDM symbols in a frame. In the figure, TEP n,m denotes n^{th} turbo encoded packet for the m^{th} MLC. In that figure:

- a. MLC 1 uses transmit mode 0 and requires three slots for each turbo encoded packet. It uses 3 consecutive OFDM symbols to send one turbo encoded packet.
- b. MLC 2 uses transmit mode 1 and utilizes 2 slots to transmit a single turbo encoded packet. It uses OFDM symbols n and $n+1$, to send two turbo encoded packets.
- c. MLC 3 uses transmit mode 2 and requires 1.5 slots for transmitting one turbo encoded packet. It uses three consecutive OFDM symbols to transmit 6 turbo encoded packets.
- d. MLC 4 uses transmit mode 1 and requires 2 slots to transmit a single turbo encoded packet. It uses 2 consecutive OFDM symbols to send two turbo encoded packets.
- e. MLC 5 uses transmit mode 3 and requires 1 slot to transmit a turbo encoded packet. It uses one OFDM symbol to send a turbo encoded packet.

Slot Scrambling

[00323] The bits of each allocated slot buffer shall be scrambled as specified in 0. The scrambled slot buffer is denoted by SB.

Mapping of Bits to Modulation Symbols

[00324] For the Wide-area Data Channel, depending on the transmit mode, either QPSK, 16-QAM or Layered Modulation may be used.

QPSK Modulation

[00325] Each group of two consecutive bits from the i^{th} scrambled slot buffer, $SB(i,2k)$ and $SB(i,2k + 1)$, $i=1,2,\dots,7$, $k = 0,1,\dots,499$, which are labeled as s_0 and s_1 , respectively, shall be mapped into a complex modulation symbol $MS = (mI, mQ)$ as specified in

Table 6 with $D = 1/\sqrt{2}$. FIG. 13 shows the signal constellation for the QPSK modulation.

16-QAM Modulation

[00326] Each group of four consecutive bits from the i^{th} scrambled data slot buffer, $SB(i,4k)$, $SB(i,4k+1)$, $SB(i, 4k+2)$ and $SB(i,4k+3)$, $i=1,2,...,7$, $k = 0,1,...,499$ shall be grouped and mapped to a 16-QAM complex modulation symbol $S(k)=(m_I(k), m_Q(k))$, $k = 0,1,...,499$ as specified in Table 17 below with $A = 1/\sqrt{10}$. FIG. 33 shows the signal constellation of the 16-QAM modulator, where $s_0=SB(i,4k)$, $s_1=SB(i,4k+1)$, $s_2=SB(i,4k+2)$, and $s_3 = SB(i,4k + 3)$.

Interleaved Bits				Modulation Symbols	
s_3 $SB(i,4k + 3)$	s_2 $SB(i,4k + 2)$	s_1 $SB(i,4k + 1)$	s_0 $SB(i,4k)$	$m_Q(k)$	$m_I(k)$
0	0	0	0	3A	3A
0	0	0	1	3A	A
0	0	1	1	3A	-A
0	0	1	0	3A	-3A
0	1	0	0	A	3A
0	1	0	1	A	A
0	1	1	1	A	-A
0	1	1	0	A	-3A
1	1	0	0	-A	3A
1	1	0	1	-A	A
1	1	1	1	-A	-A
1	1	1	0	-A	-3A
1	0	0	0	-3A	3A
1	0	0	1	-3A	A
1	0	1	1	-3A	-A
1	0	1	0	-3A	-3A

Table 17 - 16-QAM Modulation Table

Layered Modulation with Base and Enhancement Components

[00327] Each group of four consecutive bits from the i^{th} scrambled data slot buffer, $SB(i,4k)$, $SB(i,4k+1)$, $SB(i,4k+2)$ and $SB(i,4k+3)$, $i=1,2,\dots,7$, $k = 0,1,\dots,499$ shall be grouped and mapped to a layered modulation complex symbol $S(k)=(m_I(k), m_Q(k))$, $k = 0,1,\dots,499$ as specified in Table 18 below. If r denotes the energy ratio between the base component and the enhancement component, then α and β shall be given by:

$$\alpha = \sqrt{\frac{r}{2(1+r)}} \quad \text{and} \quad \beta = \sqrt{\frac{1}{2(1+r)}} \quad (\text{see Table 4}).$$

[00328] FIG. 34 shows the signal constellation for the layered modulation, where $s_0=SB(i,4k)$, $s_1=SB(i,4k+1)$, $s_2=SB(i,4k+2)$, and $s_3 = SB(i,4k + 3)$. It should be noted that the procedure for filling the slot buffer(s) ensures (see FIG. 28) that bits s_0 and s_2 correspond to the enhancement component and bits s_1 and s_3 correspond to the base component.

Interleaved Bits				Modulation Symbols	
s_3 $SB(i,4k + 3)$	s_2 $SB(i,4k + 2)$	s_1 $SB(i,4k + 1)$	s_0 $SB(i,4k)$	$m_Q(k)$	$m_I(k)$
0	0	0	0	$\square\square$	$\square\square$
0	0	0	1	$\square\square$	$\tilde{\square}\square$
0	0	1	1	$\square\square$	$\sim\square\square$
0	0	1	0	$\square\square$	$\sim\tilde{\square}\square$
0	1	0	0	$\tilde{\square}\square$	$\square\square$
0	1	0	1	$\tilde{\square}\square$	$\tilde{\square}\square$
0	1	1	1	$\tilde{\square}\square$	$\sim\square\square$
0	1	1	0	$\tilde{\square}\square$	$\sim\tilde{\square}\square$
1	1	0	0	$\sim\square\square$	$\square\square$
1	1	0	1	$\sim\square\square$	$\tilde{\square}\square$
1	1	1	1	$\sim\square\square$	$\sim\square\square$
1	1	1	0	$\sim\square\square$	$\sim\tilde{\square}\square$
1	0	0	0	$\sim\tilde{\square}\square$	$\square\square$
1	0	0	1	$\sim\tilde{\square}\square$	$\tilde{\square}\square$
1	0	1	1	$\sim\tilde{\square}\square$	$\sim\square\square$
1	0	1	0	$\sim\tilde{\square}\square$	$\sim\tilde{\square}\square$

Table 18 - Layered Modulation Table

[00329] Note that $\alpha = \sqrt{\frac{r}{2(1+r)}}$, $\beta = \sqrt{\frac{1}{2(1+r)}}$ in the above Table 18, where r is the ratio of the base component energy to the enhancement component energy

Layered Modulation with Base Component Only

[00330] The 2nd and 4th bits from each group of four consecutive bits from the i^{th} scrambled slot buffer, $SB(i, 4k+1)$ and $SB(i, 4k+3)$, $i = 1, 2, \dots, 7$, $k = 0, 1, \dots, 499$, which are labeled as s_0 and s_1 , respectively, shall be mapped into a complex modulation symbol $MS = (m_I, m_Q)$ as specified in Table 6 with $D = 1/\sqrt{2}$. FIG. 13 shows the signal constellation for the QPSK modulation.

Slot to Interlace Mapping

[00331] The mapping of slots to interlaces for the Wide-area Data Channel OFDM symbols shall be as specified herein.

Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00332] The 500 modulation symbols in each allocated slot shall be sequentially assigned to 500 interlace sub-carriers using the procedure specified herein.

OFDM Common Operation

[00333] The modulated Wide-area Data Channel sub-carriers shall undergo common operation specified herein.

Wide-area Data Channel Processing for Unallocated Slots

[00334] The unallocated slots in the Wide-area Data Channel use as input a 1000-bit fixed pattern, with each bit set to zero. These bits shall be processed according to the steps illustrated in FIG. 14.

Filling of Slot Buffer

[00335] The buffer for each unallocated slot of the Wide-area Data Channel shall be completely filled with a fixed pattern consisting of 1000 bits, with each bit set to '0'.

Slot Scrambling

[00336] The bits of each unallocated slot buffer in the Wide-area Data Channel shall be scrambled as specified in 0. The scrambled slot buffer is denoted by SB .

Modulation Symbol Mapping

[00337] Each group of two consecutive bits from the i^{th} scrambled slot buffer, $SB(i,2k)$ and $SB(i,2k + 1)$, $i=1,2,\dots,7$, $k = 0,1,\dots,499$, which are labeled as s_0 and s_1 , respectively, shall be mapped into a complex modulation symbol $MS = (mI, mQ)$ as specified in Table 6 with $D = 1/\sqrt{2}$. FIG. 13 shows the signal constellation for the QPSK modulation.

Slot to Interlace Mapping

[00338] The mapping of slots to interlaces for the unallocated slots in the Wide-area Data Channel OFDM symbol shall be as specified in 0

[00339] Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00340] The 500 modulation symbols in the slot buffer shall be sequentially assigned to 500 interlace sub-carriers as follows: the i^{th} complex modulation symbol (where $i \in \{0,1,\dots,499\}$) shall be mapped to the i^{th} sub-carrier of that interlace.

OFDM Common Operation

[00341] This modulated Wide-area Data Channel OFDM symbol sub-carriers shall undergo common operations as specified herein.

Local-area Data Channel

[00342] The Local-area Data Channel is used to carry Physical layer packets meant for Local-area multicast. The Physical layer packets for the Local-area Data Channel can be associated with any one of the active MLCs transmitted in the Local-area.

Local-area Data Channel Processing for Allocated Slots

[00343] The Physical layer packet for the Local-area Data Channel shall be processed according to the steps illustrated in FIG. 26.

[00344] For regular modulation (QPSK and 16-QAM), the physical layer packet is turbo-encoded and bit interleaved before being stored in the Data slot buffer(s). For layered modulation, the base-component Physical layer packet and the enhancement-component Physical layer packet are turbo-encoded and bit interleaved independently before being multiplexed in to the Data slot buffer(s).

Encoding

[00345] The Local-area Data Channel Physical layer packets shall be encoded with code rates $R = 1/3$, $1/2$, or $2/3$. The encoding procedure shall be identical to that for the Wide-area Data Channel as specified herein.

Bit Interleaving

[00346] The Local-area Data Channel turbo encoded packet shall be bit interleaved as specified herein.

Data Slot Allocation

[00347] For the Local-area Data Channel, the slot allocation shall be as specified herein

Filling of Data Slot Buffers

[00348] The procedure for filling the slot buffer for the Local-area Data Channel shall be as specified herein.

Slot Scrambling

[00349] The bits of each allocated slot buffer shall be scrambled as specified herein. The scrambled slot buffer is denoted by SB.

Mapping of Slot Bits to Modulation Symbols

[00350] For the Local-area Data Channel, depending on the transmit mode QPSK, 16-QAM or Layered Modulation may be used.

QPSK Modulation

[00351] Each group of two consecutive bits from the scrambled slot buffer shall be mapped in to a QPSK modulation symbol as specified herein.

16-QAM Modulation

[00352] Each group of four consecutive bits from the scrambled slot buffer shall be mapped in to a 16-QAM modulation symbol as specified herein

Layered Modulation with Base and Enhancement Components

[00353] Each group of four consecutive bits from the scrambled slot buffer shall be mapped in to a layered modulation symbol as specified herein.

Layered Modulation with Base Component Only

[00354] The 2nd and 4th bits from each group of four consecutive bits from the scrambled slot buffer shall be mapped into a QPSK modulation symbol as specified herein.

Slot to Interlace Mapping

[00355] The mapping of slots to interlaces for Local-area Data Channel OFDM symbols shall be as specified herein.

Mapping of Slot Modulation Symbols to Interlace Sub-carriers

[00356] The 500 modulation symbols in each allocated slot shall be sequentially assigned to 500 interlace sub-carriers using the procedure specified herein.

OFDM Common Operation

[00357] The modulated Wide-area Data Channel sub-carriers shall undergo common operations as specified herein.

Local-area Data Channel Processing for Unallocated Slots

[00358] The unallocated slots in the Local-area Data Channel use as input a 1000-bit fixed pattern, with each bit set to zero. These bits shall be processed according to the steps illustrated in FIG. 14.

Filling of Slot Buffers

[00359] The buffer for each unallocated slot of the Local-area Data Channel shall be completely filled with a fixed pattern consisting of 1000 bits, with each bit set to '0'.

Slot Scrambling

[00360] The bits of each unallocated slot buffer in the Wide-area Data Channel shall be scrambled as specified in 0. The scrambled slot buffer is denoted by SB.

Modulation Symbol Mapping

[00361] Each group of two consecutive bits from the scrambled slot buffer shall be mapped in to a QPSK modulation symbol as specified herein.

Slot to Interlace Mapping

[00362] The mapping of slots to interlaces for the unallocated slots in the Local-area Data Channel OFDM symbol shall be as specified herein.

Mapping of Slot Buffer Modulation Symbols to Interlace Sub-carriers

[00363] The 500 modulation symbols in the slot buffer shall be sequentially assigned to 500 interlace sub-carriers as follows: the i^{th} complex modulation symbol (where $i \in \{0, 1, \dots, 499\}$) shall be mapped to the i^{th} sub-carrier of that interlace.

OFDM Common Operation

[00364] This modulated Local-area Data Channel OFDM symbol sub-carriers shall undergo common operations as specified herein.

Mapping of Slots to Interlaces

[00365] The slot to interlace mapping varies from one OFDM symbol to the next as specified in this section. There are 8 slots in every OFDM symbol. The FDM Pilot Channel shall utilize slot 0. Slot 0 shall be assigned interlace $I_p[j]$ for OFDM symbol index j in a superframe as follows:

if $(j \bmod 2 = 0)$, then $I_p[j] = 2$.

Otherwise, $I_p[j] = 6$

[00366] The interlace assignment procedure for slot 0 ensures that the FDM Pilot Channel is assigned interlace 2 and 6 for even and odd OFDM symbol indices respectively. The remaining 7 interlaces in each OFDM symbol are assigned to slots 1 through 7. This is illustrated in FIG. 35, where P and D denote the interlaces assigned to the slots occupied by the FDM Pilot Channel and the Data Channel, respectively.

[00367] The slot to interlace mapping for slots 1 through 7 shall be as follows:

- a. Let i be the 3-bit value of the interlace index i ($i \in \{0, 7\}$). Denote the bit-reversed value of i as i_{br} .
- b. Let I_j denote the j^{th} interlace as defined earlier herein. Permute the interlace sequence $\{I_0 I_1 I_2 I_3 I_4 I_5 I_6 I_7\}$ by replacing the index i ($i \in \{0, 7\}$) in I_i with i_{br} to generate the permuted sequence, $PS = \{I_0 I_4 I_2 I_6 I_1 I_5 I_3 I_7\}$.
- c. Club interlaces I_2 and I_6 in the PS to generate shortened interlace sequence, $SIS = \{I_0 I_4 I_2/I_6 I_1 I_5 I_3 I_7\}$.

- d. For the OFDM symbol with index j ($j \in \{1, 1199\}$) in a superframe, perform a right hand cyclic shift on SIS in step 3, by a value equal to $(2 \times j) \bmod 7$ to generate the permuted shortened interlace sequence PSIS(j).
- e. If $(j \bmod 2 = 0)$, then choose interlace I_6 in the PSIS(j). Otherwise, choose I_2 in the PSIS(j).
- f. For the j^{th} OFDM symbol interval in a superframe, the k^{th} data slot (for $k \in \{1, \dots, 7\}$) shall be assigned the interlace PSIS(j)[$k-1$].

[00368] It is noted for step c above, since interlaces 2 and interlace 6 are used alternatively for the pilot, the remaining seven interlaces are used for assignment to data slots. Additionally, it is noted that a super-frame spans 1200 OFDM symbol intervals and that slot to interlace mapping for OFDM symbol index 0 is not used. Furthermore, for step d above it is noted that the right hand cyclic shift of the sequence $s = \{1\ 2\ 3\ 4\ 5\}$ by 2 yields the sequence $s(2) = \{4\ 5\ 1\ 2\ 3\}$.

[00369] FIG. 36 illustrates the interlace assignment to all 8 slots over 15 consecutive OFDM symbol intervals. The mapping pattern from slots to interlaces repeats after 14 consecutive OFDM symbol intervals. FIG. 36 shows that all interlaces get assigned next to the Pilot interlace about the same fraction of time, and the channel estimation performance for all interlaces is about the same

OFDM Common Operation

[00370] This block transforms the complex modulation symbols $X_{k,m}$, associated with sub-carrier index k for OFDM symbol interval m , into the RF transmitted signal. The operations are illustrated in FIG. 37.

IFT Operation

[00371] The complex modulation symbols $X_{k,m}$, $k = 0, 1, \dots, 4095$, associated with the m^{th} OFDM symbol shall be related to the continuous-time signal $x_m(t)$ by the inverse Fourier Transform (IFT) equation. Specifically,

$$x_m(t) = \frac{1}{N} \sum_{k=0}^{N-1} X_{k,m} e^{j2\pi(\Delta f)_{SC} (k - \frac{N}{2})(t - T_{WGI} - T_{FGI})}, \text{ for } 0 \leq t \leq T_s'.$$

[00372] In the above equation, $(\Delta f)_{sc}$ is the sub-carrier spacing, while T_{WGI} , T_{FGI} and T_s' are defined as was discussed previously in this application

Windowing

[00373] The signal $x_m(t)$ shall be multiplied by the window function $w(t)$, where

$$w(t) = \begin{cases} 0.5 + 0.5 \cos(\pi + \pi t / T_{WGI}) & 0 \leq t \leq T_{WGI} \\ 1 & T_{WGI} < t < (T_{WGI} + T_{FGI} + T_U) \\ 0.5 + 0.5 \cos(\pi + \pi (T_s' - t) / T_{WGI}) & (T_{WGI} + T_{FGI} + T_U) \leq t \leq (2 T_{WGI} + T_{FGI} + T_U) \end{cases}.$$

[00374] The windowed signal is denoted by $y_m(t)$, where

$$y_m(t) = x_m(t) w(t).$$

[00375] In the above, T_U and T_s are as defined previously herein.

Overlap and Add

[00376] The base-band signal $s_{BB}(t)$ shall be generated by overlapping the windowed, continuous-time signals from successive OFDM symbols by T_{WGI} . This is illustrated in FIG. 38. Specifically, $s_{BB}(t)$ is given by:

$$s_{BB}(t) = \sum_{m=-\infty}^{\infty} y_m(t - mT_s).$$

Carrier Modulation

[00377] The in-phase and quadrature base-band signals shall be up-converted to RF frequency and summed to generate the RF waveform $s_{RF}(t)$. In FIG. 37, $f_c(k)$ is the centre frequency of the k^{th} FLO RF channel (see Table 1).

Progressive preamble transmission and reception

[00378] In another example, the disclosed communication system may include transmission and corresponding reception of progressive preambles for use in network identification and discrimination. It is noted that, as discussed previously in connection with the examples of FIGs. 10-18, network identifiers (IDs) may be used to identify or discriminate wide-area networks and local-area networks. In those examples, four (4)

OFDM symbols in the preamble were dedicated to the TDM Pilot Channel, which included the TDM Pilot 1 channel, the Wide-area identification Channel (WIC), the Local-area Identification Channel (LIC), and the TDM Pilot 2 Channel. In the previous examples, even if a mobile receiver user only desires to received wide-area network content, for example, the receiver processes both the WIC and LIC channels.

[00379] In the present example, a wide-area operational infrastructure ID (WOI ID) and a local operational infrastructure ID (LOI ID) are transmitted in separate OFDM symbols, where a mobile transceiver need only acquire the WOI ID in one OFDM symbol in order to receive WOI data when only wide-area (WOI) data is desired, for example, whereas both the WOI and LOI IDs in both OFDM symbols are needed to receive local-area (LOI) data.

[00380] As implemented, the present example uses three dedicated OFDM symbols for timing and frequency acquisition, and network ID acquisition. An illustration of a portion 3900 of the preamble portion of a frame, such as a superframe, utilizing this methodology is illustrated in FIG. 39. As illustrated, three special symbol structures TDM 1 (3902), TDM 2 (3904), and TDM 3 (3906) are arranged in the illustrated preamble portion.

[00381] The first of these three symbols, TDM 1 (3902), is used for coarse timing acquisition, frame boundary demarcation, and acquisition of the carrier frequency offset similar to the examples previously described herein (e.g., TDM Pilot 1)

[00382] Symbol TDM 2 (3904) is used to transmit WOI ID information embedded pilot. FIG. 40 illustrates a more detailed drawing of the data within symbol TDM 2 (3902). TDM 2 is configured to include either four even or odd frequency interfaces filled with WOI pilot channels, which are pilots that are scrambled by PN sequences seeded with a WOI ID. As shown, in FIG. 40, the symbol 3902 includes four even frequency interlaces (0, 2, 4, 6) labeled respectively with reference numerals 4000, 4002, 4004, and 4006, are filled with WOI pilot channels. The remaining odd interlace slots 4008 are zeroed out. By utilizing either odd or even frequency interlaces, the resulting OFDM symbol waveform consists of two repeated copies of the same waveform in time domain, when transformed by the FFT from the frequency domain. Since the timing from TDM 1 is only coarse timing, having two copies of the waveform garnered from TDM 2 ensures that a full copy of the waveform can be obtained even if

the waveforms occur early or late in a sampling window time period as is illustrated in FIG. 42, which will be described later. This is distinguishable from the examples described previously in connection with FIGs. 10-18, since fine timing may be achieved using TDM 2, without the information embedded the TDM 3 symbol. In contrast, the previously disclosed examples require information from a TDM Pilot 1 channel, a WIC channel, a LIC channel, and a TDM 2 Pilot channel to achieve fine timing.

[00383] FIG. 41 illustrates the configuration of the TDM 3 symbol 3906, which is used to transmit WOI and LOI ID embedded pilot information. Either four even or odd interlaces (e.g., 0, 2, 4, 6) are filled with WOI and LOI pilots, such as even interlaces 4100, 4102, 4104, and 4106 as illustrated. Similar to TDM 2, the pilot channels in TDM 3 are scrambled by PN sequences, but are seeded with combination of WOI and LOI IDs. The odd or even interlacing then engenders two copies of the same waveform in time domain. It is noted that the LOI ID information that is seeded in the pilot channels is dependent on the WOI ID. For example, if it is assumed that the WOI ID can be selected from a group of 16 possible WOI IDs, and similarly that the LOI ID can be selected from another group of 16 possible LOI IDs, the processing circuitry or software in a transceiver would need to operatively process 256 different combinations (16 x 16) of WOI and LOI IDs to determine the proper combination of WOI ID and LOI ID need to receive LOI data. In the present example, however, each of the interlaces 4100, 4102, 4104, and 4106 in TDM 3 include LOI ID information that is tied to or based on the WOI ID seeded in TDM 2. Thus in this particular example, the transceiver need only needs to process 16 possible WOI IDs to obtain fine timing information from TDM 2 and then process a combination of the detected WOI ID and the additional 16 possible LOI IDs for a total of 32 processing operations.

[00384] In operation, timing acquisition according to the presently described example, begins with acquiring TDM 1 (e.g., 3902) for coarse timing and frequency as described previously herein with respect to FIGs. 10-18, for example.

[00385] After coarse timing is acquired from TDM 1 (3902), TDM 2 (e.g., 3904) is sampled starting after a quarter ($\frac{1}{4}$) of the symbol time has elapsed. As an illustration, FIG. 42 shows an exemplary symbol waveform 4200. The start of the symbol, indicated by line 4202, is determined by coarse timing acquired from TDM 1. After $\frac{1}{4}$ of the symbol time has elapsed, as indicated by line 4204, the symbol is sampled for a

half ($1/2$) symbol length, which ends at line 4206. Assuming N is a total number of samples in a symbol, the sampling of TDM 2 is performed for 1 to $N/2$ samples $\{p_k, k = 1, 2, \dots, N/2\}$. It is noted that the same sampling occurs for the symbol waveform for TDM 3, if this symbol is utilized in the case where local content is desired.

[00386] In determining the $N/2$ samples, an estimate of a noise baseline is determined from the samples. According to one example, the noise baseline may be estimated by determining a variance of the channel energy profile $|p|^2$ for a k number of samples (e.g., $N/2$). Specifically, a variance σ^2 of p may be determined using the quantitative relationship given in equation (1) below.

$$\sigma^2 = \frac{1}{N/2} \sum_{k=1}^{N/2} |p_k|^2 \quad (1)$$

Specifically, after the coarse timing is acquired from TDM1 for the start of TDM2, the first $N/4$ samples are skipped. The following $N/2$ number of samples are then sampled (e.g., see FIG. 42). The energy profiles ($|p_k|^2$) from each of those $N/2$ samples are used in Equation (1) above (i.e., p_1 is the first sample of the $N/2$ samples and $p_{N/2}$ is the last of the $N/2$ samples). In this way, as long as the timing error of TDM1 is within $(-N/4, +N/4)$, the samples ($p_1, p_2, \dots, p_{N/2}$) utilized for Equation (1) will be ensured to always contain a complete copy of the waveform.

[00387] The same samples $\{p_k, k = 1, 2, \dots, N/2\}$ are next transformed to the frequency domain using a Fast Fourier Transform (FFT). After using the FFT to transform the samples to the frequency domain, pilot symbols are descrambled using PN sequences associated with an m^{th} WOI ID from an M number of possible WOI IDs. The descrambled pilot symbols are transformed back to time domain with an Inverse Fast Fourier Transform (IFFT) to obtain channel estimates c_k for each of the samples from 1 to $N/2$, (i.e., $\{c_k, k = 1, 2, \dots, N/2\}$). The detection metric E is calculated using the previously calculated noise baseline σ^2 as follows in equation (2):

$$E^{(m)} = \sum_{k=1}^{N/2} \left(|c_k^{(m)}|^2 - \eta \sigma^2 \right) \quad (2)$$

where m is the WOI ID and η is a predetermined factor that may be used to modify the desired noise threshold. The detection metric E is calculated for all M number of WOI IDs. After computing for all of the M number of WOI IDs, the detected WOI ID will be the one with the largest detection metric, which indicates that that WOI ID is the most likely the desired WOI ID since it possesses the greatest channel activity energy above the noise threshold.

[00388] The determination described above may also be repeated for determination of the LOI ID from an L number of LOI IDs. It is noted, however, that if the mobile transceiver only is set to receive WOI data, only symbol TDM2 needs to be descrambled with the detected WOI ID for WOI fine timing acquisition. The fine timing acquisition may be accomplished with any number of methods known for timing acquisition in a communication system. An example of such a method that could be utilized is described in copending U.S. Application No. 11/303,485, filed December 15, 2005, entitled "METHODS AND APPARATUS FOR DETERMINING TIMING IN A WIRELESS COMMUNICATION SYSTEM assigned to the assignee hereof, and expressly incorporated by reference herein.

[00389] As mentioned above, if a mobile transceiver is set to also received LOI data, the same procedure described above is repeated for detection of LOI ID. Detection of the LOI ID from TDM 3 uses a combination of the detected WOI ID and all possible LOI IDs. After the detection of WOI and LOI IDs, symbol TDM3 is descrambled with the detected WOI and LOI IDs and then used for LOI fine timing acquisition using any number of methods known for timing acquisition mentioned in the previous paragraph. In contrast, previously disclosed examples herein do not provide such LOI fine timing acquisition mechanisms. The lack of such mechanisms could potentially compromise LOI data reception performance.

[00390] FIG. 43 is a block diagram of an exemplary transceiver 4300 that may employ apparatus to effect the above-described methodology for receiving TDM 1, TDM 2, and TDM 3 symbols and acquiring fine timing based on either TDM2, in the case where only WOI data is desired, or TDM 3, when WOI and LOI data is desired. As illustrated, the transceiver 4300 includes an antenna 4302 to receive transmitted wireless information, which includes TDM 1, TDM 2 and TDM 3 in the preamble of a superframe, for example. The antenna 4302 delivers the wireless signal information to

an analog-to-digital (A/D) converter 4304 that converts the analog wireless signal to a digital signal 4306. A/D converter 4304 then outputs the digital signal 4306 to a sampler 4308 or similarly suitable device. Functionally, the sampler 4308 is the portion of the transceiver 4300 that effects a timing window for sampling the subcarriers within the digital signal 4306. The output of the sampler 4310 is input to both a processor 4312 and a FFT 4314. It is noted that the processor 4312 may be implemented by a DSP or any other suitable processor.

[00391] The FFT 4314 is configured to transform samples from the sampler 4308 to frequency domain, and pass the frequency domain to a descrambler or decoder 4316, which uses PN sequences associated with the m^{th} WOI ID from the M possible WOI IDs to descramble pilot symbols scrambled by the PN sequences.

[00392] The processor 4314 may further include a channel estimation/timing estimation 4318 and Inverse FFT (IFFT) 4320. As illustrated, the IFFT 4320 receives the descrambled pilot symbols in the frequency domain and transforms them back to time domain for use by the channel estimation/timing estimation unit 4318 to obtain channel estimates. The processor 4314 also may determine the detection metric as described above in connection with equation (2), and then detect the WOI ID based on a determination of the largest detection metric.

[00393] Additionally, the timing estimation portion of unit 4318 may utilize the data from TDM 1 to first acquire and set timing for sampling TDM 2 by starting after $\frac{1}{4}$ of the symbol time for $\frac{1}{2}$ of the symbol length, as was discussed above. Further, the timing estimation portion of unit 4318 then obtains fine timing acquisition by using data descrambled by the detected WOI for fine timing acquisition. The channel estimation/timing estimation unit 4318, in turn, outputs timing data 4322 to the sampler 4308 for setting the timing of the sampling window of sampler 4308.

[00394] Moreover, if the processor 4312 is programmed or receives instructions for receiving local data (LOI), the processor 4312 would execute the additional processing described previously for TDM 3. Otherwise, the processor 4312 is configured to recognize not to process the data in TDM 3.

[00395] It is noted that channel estimation/timing acquisition unit 4318 may be implemented as hardware, software, or firmware within a transceiver apparatus, such as transceiver 300. Additionally, in the case of a software implementation, the transceiver

300 could include an integrated circuit, such as an Application Specific Integrated Circuit (ASIC) including or interfacing with a computer readable medium having instructions stored thereon (such as a memory 4324, for example), the stored instructions, when executed by a processor (e.g., processor 4312), causing the processor to execute the methodology described in this disclosure. As another example, the processor 4312 could be implemented by a Digital Signal Processor (DSP) 316 within the transceiver 300 or as a combination of a DSP and hardware..

[00396] As shown in FIG. 43, after descrambling or demodulation, the resultant descrambled signal is output as a serial bit stream for use by a mobile communication device in which the transceiver is housed, such as a mobile phone device or a personal data assistant, as examples.

[00397] FIG. 44 shows a flow diagram of a method for transmitting wireless symbols, such as OFDM symbols, having three distinct symbols (e.g., TDM1, TDM2, and TDM3) for communicating information to a transceiver for timing acquisition. As illustrated the method 4400 begins at block 4402, where the process 4400 is initialized. Next flow proceeds to block 4402, wherein a first symbol configured to communicate at least timing information is transmitting (e.g., TDM 1).

[00398] From block 4402, flow proceeds to block 4404, where a second symbol configured to communicate first information including network identification information concerning a first network configured to communicate first information including network identification information concerning a first network is transmitted. An example of this part of the procedure is the transmission of TDM 2.

[00399] After block 4404 is executed flow proceeds to block 4406 where a third symbol configured to communicate second information including network identification information concerning a second network is transmitted. The network identification information concerning the second network includes at least a portion of the network identification information concerning the first network. An example of such a transmission is the transmission of TDM 3.

[00400] Flow then proceeds to block 4408 where the process 4400 terminates. It is noted that the process 4400 may be effected by a transmitter (not shown) or similar device. A method by which corresponding transceivers configured to receive and process the symbols transmitted is illustrated in FIG. 45.

[00401] As illustrated, FIG. 45 discloses a process 4500 for receiving and determining network identifiers, such as those transmitted by the method of FIG. 44. This process may be implemented by a transceiver, such as transceiver 4400.

[00402] Process 4500 begins at start block 4502 and proceeds to block 4504. At block 4504 where a first received symbol configured to communicate at least timing information is processed. As an example of an implementation of this procedure, the transceiver 4300 in FIG. 43 may receive TDM 1, for example, and determine coarse timing from the symbol TDM 1. After block 4504, flow proceeds to block 4506 where a second received symbol configured to communicate first information including network identification information concerning a first network is process. This process in block 4506 may be implemented by transceiver 4300 and, more particularly, by the sampler 4308, processor 4312 and channel estimation/timing estimation unit 4318.

[00403] After block 4506 is complete, flow proceeds to decision block 4508. Here a determination is made whether local data (LOI data) is desired or not. If not, flow proceeds to block 4510 where timing is acquired using only the first network data (e.g., WOI ID). After fine timing acquisition in block 4510, flow proceeds to termination block 4512.

[00404] Alternatively at decision block 4508 if second network data (e.g., LOI data) is desired, flow proceeds to block 4514. At block 4514 the procedure processes a third received symbol configured to communicate second information (e.g., LOI ID) including network identification information concerning a second network (i.e., LOI), where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network (i.e., the LOI ID detection is based on the combination of the detected WOI data processed in block 4506). After the process of block 4514 is complete, flow proceeds to block 4516, where fine timing acquisition is based on the detected first and second network identification information (i.e., WOI and LOI IDs). After timing acquisition, flow proceeds to termination block 4512.

[00405] FIG. 46 illustrates an example of a processor for use in a transmitter according to the present disclosure. As illustrated a transmitter or processor used in a transmitter 4600 includes means 4602 for transmitting a first symbol. The first symbol is configured to communication at least timing information that may be used by a receiver

for acquiring coarse timing. An example disclosed earlier of the first symbol is OFDM symbol TDM 1. Processor 4600 also includes means 4604 for transmitting a second symbol that is configured to communicate first information including network identification information concerning a first network. Examples of the second symbol include TDM 2, discussed above, which includes WOI ID information concerning the WOI network.

[00406] Processor 4600 also includes means 4606 for transmitting a third symbol configured to communicate second information including network identification information concerning a second network. The network identification information concerning the second network also includes at least a portion of the network identification information concerning the first network. An example of such a third symbol includes TDM 3, which features LOI ID information based on WOI ID information, where the LOI ID is used for accessing the LOI network.

[00407] Processor 4600 also includes transmitting circuitry or means 4608 for assembling the symbols from means 4062, 4604, and 4608 into a frame or superframe, such as illustrated in FIG. 39, as an example. The frame or superframe is then transmitted wirelessly via an antenna 4610.

[00408] FIG. 47 illustrates an exemplary transceiver or processor within a transceiver 4700 that is configured to receive wireless communication signals. As illustrated, the processor 4700 is in communication with an antenna 4702 that receives the wireless communication signals arranged in a frame, such as that illustrated in FIG. 39. The signals are delivered, for example, to means 4704 for processing a first received symbol, where the first received symbol is configured to communicate first timing information to the transceiver or processor 4700. This information may be similar to symbol TDM 1 discussed above and is used, for example, to effect coarse timing acquisition as also previously described. Additionally, the processor 4700 includes a means 4706 in communication with means 4704, means 4706 for processing a second received symbol configured to communicate first information including network identification information concerning a first network. This second received symbol may be TDM 2, for example, which communicates the WOI ID concerning the WOI network.

[00409] Processor 4700 further includes means 4708 in communication with means 4706, where means 4708 is for selectively processing a third received symbol configured to communicate second information including network identification

information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network when the transceiver is selectively configured to receive data from the second network. An example of this third symbol may be, for example, TDM 3 communicating the LOI ID based on the WOI ID, as described previously herein.

[00410] Processor 4700 also includes processing circuitry in communication with means 4706 and 4708 for, among other things, acquiring timing of either the WOI data or the WOI and LOI data dependent on whether the LOI data is desired. It is noted that means 4704, 4706, 4708, and 4710 may be effected by some or all of the components illustrated in FIG. 43, as an example.

[00411] The previously disclosed examples in connection with FIGs. 39-47, by featuring a progressive or selective use of symbols in a frame preamble, afford better use of processing resources, particularly if only WOI data is desired, since processing of only two frames (i.e., TDM1 and TDM2) is needed. Furthermore, by utilizing a third symbol for fine timing acquisition of LOI data reception that utilizes a combination of the WOI ID and all possible LOI IDs, processing resources are optimized when LOI data is desired. By requiring less processing resources, smaller chip or processor sizes may be garnered.

[00412] The various illustrative logical blocks, modules, and circuits described in connection with the embodiments disclosed herein may be implemented or performed with a general purpose processor, a digital signal processor (DSP), an application specific integrated circuit (ASIC), a field programmable gate array (FPGA) or other programmable logic device, discrete gate or transistor logic, discrete hardware components, or any combination thereof designed to perform the functions described herein. A general purpose processor may be a microprocessor, but in the alternative, the processor may be any conventional processor, controller, microcontroller, or state machine. A processor may also be implemented as a combination of computing devices, e.g., a combination of a DSP and a microprocessor, a plurality of microprocessors, one or more microprocessors in conjunction with a DSP core, or any other such configuration.

[00413] The steps of a method or algorithm described in connection with the embodiments disclosed herein may be embodied directly in hardware, in a software module executed by a processor, or in a combination of the two. A software module may reside in RAM memory, flash memory, ROM memory, EPROM memory, EEPROM memory, registers, hard disk, a removable disk, a CD-ROM, or any other form of storage medium known in the art. An exemplary storage medium is coupled to the processor such the processor can read information from, and write information to, the storage medium. In the alternative, the storage medium may be integral to the processor. The processor and the storage medium may reside in an ASIC. The ASIC may reside in a user terminal. In the alternative, the processor and the storage medium may reside as discrete components in a user terminal.

[00414] The previous description of the disclosed embodiments is provided to enable any person skilled in the art to make or use the present invention. Various modifications to these embodiments will be readily apparent to those skilled in the art, and the generic principles defined herein may be applied to other embodiments without departing from the spirit or scope of the invention. Thus, the present invention is not intended to be limited to the embodiments shown herein but is to be accorded the widest scope consistent with the principles and novel features disclosed herein.

[00415] Those of skill in the art would understand that information and signals may be represented using any of a variety of different technologies and techniques. For example, data, instructions, commands, information, signals, bits, symbols, and chips that may be referenced throughout the above description may be represented by voltages, currents, electromagnetic waves, magnetic fields or particles, optical fields or particles, or any combination thereof.

[00416] Those of skill would further appreciate that the various illustrative logical blocks, modules, circuits, and algorithm steps described in connection with the embodiments disclosed herein may be implemented as electronic hardware, computer software, or combinations of both. To clearly illustrate this interchangeability of hardware and software, various illustrative components, blocks, modules, circuits, and steps have been described above generally in terms of their functionality. Whether such functionality is implemented as hardware or software depends upon the particular application and design constraints imposed on the overall system. Skilled artisans may

implement the described functionality in varying ways for each particular application, but such implementation decisions should not be interpreted as causing a departure from the scope of the present invention.

CLAIMS

WHAT IS CLAIMED IS:

1. A method for transmitting network identifiers in a communication system comprising:

transmitting a first symbol configured to communicate at least timing information;

transmitting a second symbol configured to communicate first information including network identification information concerning a first network; and

transmitting a third symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network.

2. The method as defined in claim 1, wherein the second symbol is configured to include the first information including the network identification information having first network identification information scrambled by pseudo random noise sequences seeding with the symbol with the first network identification information.

3. The method as defined in claim 1, wherein the second symbol is configured to include the first information including the network identification information having first network identification information scrambled by pseudo random noise sequences seeding with the symbol with the first network identification information.

4. A method for determining network identifiers in a communication system in a transceiver, the method comprising:

processing a first received symbol configured to communicate first timing information to the transceiver;

processing a second received symbol configured to communicate first information including network identification information concerning a first network; and

selectively processing a third received symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network when the transceiver is selectively configured to receive data from the second network.

5. The method as defined in claim 4, further comprising:

acquiring fine timing in the transceiver based on at least one of the first information including network identification information concerning a first network when second network information is not desired.

6. The method as defined in claim 4, further comprising:

acquiring fine timing in the transceiver based on at least one of the first and second information including network identification information concerning a first network when second network information is desired.

7. The method as defined in claim 4, wherein the first timing information is coarse timing information.

8. The method as defined in claim 7, further comprising:

sampling at least one of the second received symbol and the third received symbol based on the coarse timing information.

9. The method as defined in claim 4, further comprising:

estimating a noise baseline for at least one of the second and third received symbols based on the first timing information.

10. The method as defined in claim 8, further comprising:
 - estimating a noise baseline for at least one of the second and third received symbols for at least one of the second received symbol and the third received symbol based on the coarse timing information.
11. The method as defined in claim 4, wherein the second received symbol is configured to include the first information including network identification information concerning the first network in one of even interlaces or odd interlaces within the second received symbol.
12. The method as defined in claim 4, wherein the third received symbol is configured to include the second information concerning the second network in one of even interlaces or odd interlaces within the third received symbol.
13. The method as defined in claim 4, further comprising:
 - transforming at least one of the sampled second and third received symbol to frequency domain;
 - descrambling pilot symbols embedded within at least one of the second and third received symbols using pseudorandom noise sequences;
 - transforming the descrambled pilot symbols to time domain;
 - determining channel estimates for at least one of the transformed descrambled pilot symbols associated with at least one of the second and third received symbols for a plurality of network identifiers;
 - calculating a detection metric based on the determined channel estimates and the noise baseline based on ;and
 - selecting a network identifier within the network identification information from the plurality based on the largest value from the detection metric.
14. A processor for use in a transmitter, the processor configured to:
 - transmit a first symbol configured to communicate at least timing information;
 - transmit a second symbol configured to communicate first information including network identification information concerning a first network; and

transmit a third symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network.

15. The processor as defined in claim 14, wherein the second symbol is configured to include the first information including the network identification information having first network identification information scrambled by pseudo random noise sequences seeding with the symbol with the first network identification information.

16.. The processor as defined in claim 1, wherein the second symbol is configured to include the first information including the network identification information having first network identification information scrambled by pseudo random noise sequences seeding with the symbol with the first network identification information.

17. A processor for use in a transceiver, the processor configured to:
process a first received symbol configured to communicate first timing information to the transceiver;
process a second received symbol configured to communicate first information including network identification information concerning a first network; and
selectively process a third received symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network when the transceiver is selectively configured to receive data from the second network.

18. The processor as defined in claim 17, wherein the processor is further configured to acquire fine timing in the transceiver based on at least one of the first information including network identification information concerning a first network when second network information is not desired.

19. The processor as defined in claim 17, wherein the processor is further configured to acquire fine timing in the transceiver based on at least one of the first and second

information including network identification information concerning a first network when second network information is desired.

20 The processor as defined in claim 17, wherein the first timing information is coarse timing information.

21. The processor as defined in claim 20, wherein the processor is further configured to sample at least one of the second received symbol and the third received symbol based on the coarse timing information.

22. The processor as defined in claim 17, wherein the processor is further configured to estimate a noise baseline for at least one of the second and third received symbols based on the first timing information.

23. The processor as defined in claim 21, wherein the processor is further configured to estimate a noise baseline for at least one of the second and third received symbols for at least one of the second received symbol and the third received symbol based on the coarse timing information.

24. The processor as defined in claim 17, wherein the second received symbol is configured to include the first information including network identification information concerning the first network in one of even interlaces or odd interlaces within the second received symbol.

25. The processor as defined in claim 17, wherein the third received symbol is configured to include the second information concerning the second network in one of even interlaces or odd interlaces within the third received symbol.

26. The processor as defined in claim 17, wherein the processor is further configured to:

transform at least one of the sampled second and third received symbol to frequency domain;

descramble pilot symbols embedded within at least one of the second and third received symbols using pseudorandom noise sequences;

transform the descrambled pilot symbols to time domain;

determine channel estimates for at least one of the transformed descrambled pilot symbols associated with at least one of the second and third received symbols for a plurality of network identifiers;

calculate a detection metric based on the determined channel estimates and the noise baseline based on ;and

select a network identifier within the network identification information from the plurality based on the largest value from the detection metric.

27. A processor for use in a transmitter comprising:

means for transmitting a first symbol configured to communicate at least timing information;

means for transmitting a second symbol configured to communicate first information including network identification information concerning a first network; and

means for transmitting a third symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network

28. A processor for use in a transceiver comprising:

means for processing a first received symbol configured to communicate first timing information to the transceiver;

means for processing a second received symbol configured to communicate first information including network identification information concerning a first network; and

means for selectively processing a third received symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information

concerning the first network when the transceiver is selectively configured to receive data from the second network.

29. A computer-readable medium encoded with a set of instructions, the instructions comprising:

- an instruction for transmitting a first symbol configured to communicate at least timing information;

- an instruction for transmitting a second symbol configured to communicate first information including network identification information concerning a first network; and

- an instruction for transmitting a third symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network.

30. A computer-readable medium encoded with a set of instructions, the instructions comprising:

- an instruction for processing a first received symbol configured to communicate at least timing information to the transceiver;

- an instruction for processing a second received symbol configured to communicate first information including network identification information concerning a first network; and

- an instruction for selectively processing a third received symbol configured to communicate second information including network identification information concerning a second network, where the network identification information concerning the second network includes at least a portion of the network identification information concerning the first network when the transceiver is selectively configured to receive data from the second network.
