

PROCESS AND APPARATUS FOR THE PRODUCTION OF A HEART
VALVE PROSTHESIS

The invention relates to a process according to the precharacterising clause of Claim 1 and to an apparatus for carrying it out.

The known prostheses used in cardiac surgery contain a crown-shaped annular element of plastic, but generally of metal or of both materials. They consist in general of long, often wire-like elements which are predominantly not very elastic and are often joined by soldering or welding. This results in poor adaptability, especially since the joints then become brittle, but in some cases also relatively poor tolerance, not least because the textile covering generally applied to the annular element then requires several seams in order to hold securely on the wire skeleton of the annular element, with the result that strength problems may also occur and manufacture is made more difficult. Typical heart valve prostheses of this type are described in U.S. Patent 3,570,014 or U.S. Patent 3,755,823.

It is the object of the invention to design a heart valve prosthesis of the type stated at the outset in such a way that the adaptability and tolerance are improved, strength problems being avoided. This is achieved according to the invention by the characterising features of Claim 1.

By means of the process according to the invention, the textile covering is mounted on the annular element with a minimum of seams. Thus, on the one hand, the tolerance improves since a plurality of thick seams is avoided but the strength is also improved as a result, since seams always entail a mechanical risk. It would of course also be possible to apply the process according to the invention to conventional annular elements, but it is precisely in

SUBSTITUTE SHEET

This Sheet Has Been Replaced

combination with such a support which results in an optimum which has a form according to a simultaneously submitted patent application and is shown here.

5 Although the process according to the invention could also be realised without an apparatus of a particular type, the apparatus according to the invention according to Claim 6 not only considerably helps and facilitates the implementation of the process and the production of a prosthesis according to the
10 invention but also guarantees uniform quality through the clamping apparatus provided according to the invention.

Further details of the invention are evident from the following description of embodiments shown
15 schematically in the drawing.

Fig. 1 shows a heart valve prosthesis according to the invention before attachment of the biological heart valve material;

20 Fig. 2 to 6 show the successive steps in carrying out the process according to the invention, starting from a rectangular piece of material according to Fig. 2; and

Fig. 7 shows an apparatus according to the invention for carrying out this process.

25 Fig. 1 shows an oblique view of a heart valve prosthesis 1 according to the invention with partly removed textile covering 3, which covers an annular support 1a together with a collar 2 attached thereto. As can be seen, the annular element 1a consists of flat
30 material, in particular of a thermoplastic, so that it can be produced easily and economically, for example by injection moulding.

The support 1a possesses, in a manner known per se, three axially projecting support arms 4, the free
35 ends of which are rounded. Projections 5 and indentations 6 are arranged alternately on the axial end, the base B, of this support 1a, which end is

5 opposite the support arms 4, it being possible for any excess biological heart valve material which is to be flattened in a conventional manner over the support arms and is to be fastened to the collar 2 to be accommodated in said indentations.

10 The textile covering 3 is elastic and consists expediently of a network fabric, because such a fabric has sufficient intrinsic elasticity - even when conventional, biologically tolerated textile material is used. In practice, a USCI product, Adavison, from C.R. Bard, Catalogue No. 007831, has proved expedient. This is all the more surprising since nonelastic coverings have been chosen to date; however, it will subsequently become clear that the choice of elastic material results in a simplification in the manufacture of the heart valve prosthesis, improved safety with respect to tearing of seams and a smaller number of such seams, which also improves the tolerance of the prosthesis. This is because in many cases a concealed (and therefore invisible) circumferential seam in the region of the collar 2 will be sufficient, if necessary with a vertical seam 7.

20 In order to facilitate the process according to the invention - with optimal anatomical fit - it is expedient if the support arms 4 are rounded at their free ends with the radius R which corresponds to not more than one eighth of the diameter of the support 1a in the region of its collar 2. On the other hand, it is advantageous if the indentations 6 are relatively flat, the radius of curvature 2R preferably corresponding to not more than twice the radius of curvature R of the support arms 4. The collar 2 shown in Fig. 1 and consisting of textile or plastic material is expediently mounted between two circumferential lines, of which the upper circumferential line is preferably located a distance a_1' of about 1 mm below the base 4a of the support arms 4 but the lower

circumferential line is advantageously slightly further away from the edges of the indentations 6, so that a distance a_2' of, for example, 2 mm results.

5 In this context, it is therefore possible first to prefabricate annular elements 1a of different diameters, preferably from 17 mm to 33 mm at the base B. In order thereafter to form a heart valve prosthesis shown in Fig. 1 therefrom, it is necessary to provide - in the manner described, a textile
10 covering 3, which state had to be produced from several individual parts, tediously and with several seams. It is therefore intended, with reference to Fig. 2 to 6, to describe the process according to the invention, in which, starting from a piece of material closed in a
15 collar-like manner, a single seam is sufficient.

According to Fig. 2, however, a prepared textile collar is not available and must first be produced from a rectangular piece of material in the manner shown. This piece of material consists of a
20 network fabric, for example a knitted fabric, having a sequence of relatively dense strips 12 formed from warp threads and sparser meshes 13 in between, which in particular give the textile covering 3 elasticity in the direction of the arrow A' whereas it has slightly
25 less elasticity in the direction at right angles thereto. A similar material has been put on the market by USCI, Adavison, from C.R. Bard, USA, under Catalogue No. 007831.

Whereas to date nonelastic coverings were used
30 in spite of the large number of seams required, the elasticity of the textile covering 3 used according to the invention allows the latter to be pulled over the support arms 4 and their base region 4a, differences in length being elastically compensated. Of course, the
35 covering 3 consists of medically or biologically tolerated textile material known per se.

Thus, in order to obtain the required collar

form according to Fig. 3, the rectangular piece of material according to Fig. 2 is bent with its ends towards one another, and the ends are then connected to one another by a vertical seam 7 (cf. Fig. 1). As can be seen, it is preferable if the edges 14 of the material are provided with a bead in order to increase the strength of the seam 7. To avoid outward-projecting material residues in the covered support 1a, the collar with its bead on the inside according to Fig. 3 is expediently turned outwards before being pulled into the support 1a.

The collar-like fabric sleeve thus formed is pulled through the annular element 1a from the inside according to Fig. 4, so that the collar 3 is coaxial with said annular element and the axial ends of the textile covering project above and below the annular element. From this explanation, it is of course clear that Fig. 3 merely shows a section of the collar, which - in order to be able to project above the support 1a and below the latter - must have a diameter which is substantially smaller than the length of the collar 3.

In any case, the upper projecting end 15 of the covering 3 can thus be turned outwards and downwards in the manner shown in Fig. 4, whereas the lower projecting end 16 is turned outwards from the bottom. If a collar 2 (Fig. 1) is to be mounted, it is expedient if the lower end 16 is chosen to be slightly longer than the upper end 15, since it is intended to be used for covering the collar 2. It is of course also clear that Fig. 4 shows the covering 3 in a partially cut away view with the central strip omitted, since the collar 3 according to Fig. 3 does in fact form a closed hollow cylinder. This section view according to Fig. 4 is merely intended to illustrate the path of the two ends 15 and 16.

As soon as the two ends 15, 16 have been turned into the position shown in Fig. 4, all that is still

required is a circumferential seam 17 to sew together the joining points 18 of the two ends 15, 16, which joining points have been pulled together. If the starting material used was already a collar-shaped fabric, for example a hollow network article, the seam 17 is the only seam required for the covering and, when a collar 2 is mounted, even this seam is covered by said collar. Instead of a hollow network article, it is also possible to use hollow knitted fabric, network material being preferred because it has intrinsic elasticity which is due to the method of production and is not associated with the use of an elastic material, although such a material could also be used within the scope of the invention, provided it is biologically tolerated. As is evident and is confirmed in practice, this intrinsic elasticity above all compensates any difference in length which, in the case of the support arms 4 with their base area 4a in between, is particularly large. Nevertheless, there is no danger of overstretching of the fabric 3, and the direction of extension along arrow A' of Fig. 2 has proved in practice to be more advantageous than the reverse direction.

Once this point of the process has been reached, it is still necessary to place a plastic piece or the like which forms a collar 2, and has a cross-section which is angular, for example rectangular, but according to Fig. 5 in this case triangular, on the projecting and the short end 15. It may be advantageous to fasten the collar 2 with the aid of a few cross stitches 19 or zig-zag stitches 20 the annular element 1a in order to prevent slipping or twisting and for this purpose small through-holes (not shown) may be made in the support 1a, in particular in the region of the upper circumferential line (cf. the upper limit of the collar 2), but in any case along the lower circumferential line (that is to say at the lower limit of the collar 2 or between these lines) in order

THIS SHEET HAS BEEN
REPLACED

to facilitate this connection.

5 The lower, longer end 16 is now folded over the upper surface of the collar 2 (Fig. 6) and around the inner lateral surface of said collar in such a way that the latter is covered by a section 21 and the former by a section 22. This is of course only necessary when the collar 2 is not itself formed from textile material or covering by the textile covering 3 is desired for other reasons, said covering also being used for
10 anchoring in the biological tissue. The turning over of the end section 21 makes it possible to conceal this end and to fasten it to the covering or, if necessary, also to the annular element 1a with the aid of a concealed seam 23, for which purpose the above-mentioned, very small through-holes arranged in the
15 region of the circumferential lines determined by the collar 2 may be used.

By applying the concealed seam 23 in the region of the previously applied seam 17 (Fig. 4), both seams
20 are covered by the collar 2 in such a way that, on the one hand, they are virtually completely invisible from the outside or merge to form a single seam. However, this seam 23 can of course also help to fasten the two end sections 15, 16 (Fig. 4), so that the seam 17 may
25 be in the form of a relatively loose quilting seam. In the final analysis, the appearance of the heart valve prosthesis 1 shown in Fig. 1 is then achieved.

To be able to carry out the process described above in a simplified manner, it is preferable to
30 provide an apparatus according to Fig. 7. This has essentially two rings 33, 34, the internal diameter of which is sufficiently large to hold a complete prosthesis 1, that is to say a prosthesis 1 formed from support 1a and textile covering 3. A certain
35 additional play between the outer diameter of the annular element 1a reinforced with the covering 3 and the internal diameter of the rings 33, 34 makes it

possible to apply an all-round seam at a point 24 within the internal diameter of the rings 33, 34, as will be explained below.

5 First, however, the annular element 1a, with collar 3 inserted through from the inside, is placed in the inner opening 25 of the rings 33, 34. Thereafter, the lower end 16 is then expediently turned outwards over the outer surface of the annular element 1a and is fastened carefully to the lower ring 33 so that it
10 rests with its end section 21', in each case with the same length over the entire circumference, on a support surface 26 of the ring 33. In this position, the lower end 16 is detachably fixed, for example with the aid of a clamping ring 28. This clamping ring can be in the
15 form of a spring ring or in the form of a circumferential ring which can be clamped, for example, with the aid of a toggle lever apparatus (not shown), the first embodiment being preferred. In order to enlarge the clamping area, it is advantageous if the
20 ring 33 has a circumferential seam 27 including the ring 26 together with the piece of fabric clamped by it.

After the lower end 16 has been fastened to the lower ring 33 in this manner, the upper end can be
25 pulled over the support arms 4 and the regions 4a present in between. The upper end 15 is then fastened to the clamping apparatuses 29, which for this purpose are equipped with gripping elements 41, for example with hooks (as shown), but if necessary also with
30 forceps-like grippers. These gripping elements 41 are connected to tension elements, such as springs 30, and are subjected to a load by these, it being advantageous if the spring force is adjustable with the aid of an
35 adjusting screw 40 in order to be able to adapt it to different prosthesis sizes. On the other hand, adaptation may also be necessary when different coverings are used, since it will generally be

5 necessary also to change the rings 33, 34 when the size of the prostheses 1 is changed, unless the diameter is adjusted by inserting a suitable sleeve into each of the rings 33, 34, which is also possible within the scope of the invention.

10 Furthermore, the section through the rings 33, 34 shows that the inner surfaces thereof are preferably inclined towards the clamping point at which the ends 15, 16 meet one another, in order to improve the accessibility during sewing. To return to the clamping apparatuses 29, it may be mentioned that it is advantageous if the particular clamping force set can be read on a scale 42 connected to the adjusting screw 40. In order to distribute the clamping force as
15 uniformly as possible over the circumference of the ring 34, a plurality of clamping apparatuses 29, which are indicated merely by their axes 29', is expediently distributed over the circumference of this ring. In order to support these clamping apparatuses 29 on the
20 outside of the ring 34, the latter consists of an inner ring section 35 and an outer ring section 36 on which the clamping apparatuses 29 are fastened. This results in a cavity 31 between the two ring sections 35, 36, in which cavity, as shown, the gripping elements 41 are
25 housed.

Of course, Fig. 7 merely illustrates a preferred embodiment and it would be quite possible to modify the ring 34 so that the gripping means 41 are also readily accessible when rings 33, 34 are placed
30 together, in which case it would also be possible to apply the seam 17 (cf. Fig. 4) not inside the opening 25 but instead just on the outside of the inner ring section 35, in other words where the cavity 31 is located in Fig. 7. However, this requires that, after
35 the rings 33, 34 have been slackened, the textile covering is placed around the annular element 1a under less tension than when the seam is applied, in other

THIS SHEET HAS BEEN REPLACED

words the fabric would have to be more greatly stretched during sewing, which on the one hand would make measurement of the clamping force with the aid of the clamping apparatuses more difficult (where these can be provided at all) and on the other hand would give rise to the danger of overextension of the textile covering 3.

An apparatus as shown in Fig. 7 could also be used for applying a different type of seam connection if, for example, one of the two rings 33, 34 or both rings 33, 34 are equipped with a heatable ring region, thus permitting heat bonding or welding of the two fabric ends 15, 16. However, a weld seam or bonded seam, the production of which is generally simpler, is generally thicker and especially less elastic than a sewn seam, which is therefore preferable for heart prostheses of this type.

In order to hold the rings 33, 34 securely during the operations described above, it is expedient to provide a stand 51 which - for holding the support 1a at the desired working height - is advantageously provided with a retaining bush 32 which is adjustable in height and can be screwed to various depths into the stand 51.

The rings 33, 34, which are held in the indicated clamping position by corresponding clamping means, such as clamping screws 44 or clamps, during application of the seam 17 (Fig. 4), are expediently guided on the stand 51 with the aid of guide columns 37 but can be secured on the latter in the position lowered towards the retaining bush 32 with the aid of adjusting rings 43 which can be moved along the columns 37 and clamped to said columns or with the aid of other blocking elements. After application of the seam 17 inside the opening 25, the collar 2 can be mounted according to Fig. 5, after which the projecting end 15 is cut off.

This Sheet Has Been Replaced

THIS SHEET HAS BEEN REPLACED

5 In practice, either a human (if desired also
animal) pulmonary or aortic valve is stored in a
nutrient solution (together with antibiotics and other
substances) and is sewn to the prosthesis described
10 shortly before use, or the already assembled components
of the prosthesis are stored or frozen together in a
nutrient solution until they are required. This also
enables a high cell survival rate to be achieved, and
the prostheses produced in this manner can be used in
15 four different positions.

It should be mentioned that the positioning
rings 43 constitute an additional element for holding
the rings in the lower position in their mutual
clamping position and thus, if necessary, facilitating
15 subsequent pulling of the covering 3. Only when the
fabric has been pulled uniformly over the annular
element 1a and the meshes run straight along the
generatrices of the slightly conical ring 1a is it
expedient to effect the final clamping by means of the
20 screws 44.

A large number of modifications are possible
within the scope of the invention; thus, the function
of the rings 33, 34 could be interchanged with one
another by, for example, providing the fastening 27, 28
25 on the upper ring 34 and the clamping apparatus 29 on
the lower ring.

PATENT CLAIMS

1. Process for covering an annular support (1a) for a heart valve prosthesis (1) which has, at one axial end, axially projecting support arms (4) which are distributed over the circumference and are rounded at the free end, having a textile covering (3), characterised in that the textile covering (3), starting from a collar shape, is elastic at least in one direction (A'), is pushed into the annular element (1a) and, at its two projecting axial ends (15, 16) is turned over the outer surface of said annular element, after which the two ends (15, 16) are joined to one another all round by a seam (17).
2. Process according to Claim 1, characterised in that the collar shape of the textile covering (3) is produced starting from an approximately rectangular piece of material, first by sewing together two opposite sides of the piece of material, in particular with edges (14) having outer beads.
3. Process according to Claim 1 or 2, characterised in that the all-round seam (17) is applied at a distance (a1) of about 1 mm from the start of the support arms (4), and preferably a distance (a2) from the base (8), preferably a2 is > a1, in particular a2 is about equal to 2a1.
4. Process according to any of the preceding Claims, characterised in that the textile covering (3) used is a network material, preferably one having alternately denser strips (12) running in the axial direction of the collar and looser meshes (13), the elasticity in the direction of the strips (12) being smaller than at right angles thereto.
5. Process according to any of the preceding Claims, for a support having a collar, characterised in that the two ends (15, 16) are joined to one another in such a way that at least one of the ends (15 or 16)

This Sheet Has Been Replaced

13

projects above the seam (17), whereupon a collar (2), in particular of textile or plastic material, preferably having an angular, for example triangular, cross-sectional form is mounted in the region of the seam (17) and is enveloped with the projecting end (16), the envelope expediently being sewn, preferably with a concealed seam (23).

6. Apparatus for carrying out the process according to any of Claims 1 to 4, characterised in that it has two coaxial rings (33, 34) with a central opening (25) holding the annular element (1a) together with the covering (3) of which one ring (33) is provided with a fastening means (27, 28) for one end (16) of a covering (3) and the other ring (34) is provided with a clamping apparatus (29) for the other end (15) of the covering (3).

7. Apparatus according to Claim 6, characterised in that the opening (25) of the rings (33, 34) has adequate dimensions within the opening (25) for applying the seam (17) around the inserted annular element (1a).

8. Apparatus according to Claim 6 or 7, characterised in that the clamping apparatus (29) comprises a plurality of clamping elements (29) distributed over the circumference of the ring (34), each of which is preferably provided with a gripping element (41) for the textile covering (3), for example in the form of a hook.

9. Apparatus according to any of Claims 6 to 8, characterised in that it has an adjusting and/or indicating means (40, 42) for the applied clamping force, preferably an adjustable spring (30).

10. Apparatus according to any of Claims 6 to 9, characterised in that at least one clamping means (43 or 44) is provided for holding the rings (33, 34) in a position clamping the covering (3).

11. Apparatus according to any of Claims 6 to 10, characterised in that a stand (51) is coordinated with

This Sheet Has Been Replaced

the rings (33, 34), by means of which stand they can be held in a predetermined position, and that this stand (51) preferably has at least one of the following features:

- a) it has a supporting base (32) which is adjustable in height for holding the annular element (1a) at the desired height;
- b) it has a straight-line guide (37), in particular having guide columns (37), for moving the rings (33, 34) while retaining their relative positions.
