## FIELD OF THE INVENTION

The present invention relates to various prodrugs of monomethyl fumarate. In particular, the present invention relates to derivatives of monomethyl fumarate which offer improved properties relative to dimethyl fumarate. The invention also relates to methods of treating various diseases.

## BACKGROUND OF THE INVENTION

Fumaric acid esters (FAEs) are approved in Germany for the treatment of psoriasis, are being evaluated in the United States for the treatment of psoriasis and multiple sclerosis, and have been proposed for use in treating a wide range of immunological, autoimmune, and inflammatory diseases and conditions.

FAEs and other fumaric acid derivatives have been proposed for use in treating a wide-variety of diseases and conditions involving immunological, autoimmune, and/or inflammatory processes including psoriasis (Joshi and Strebel, WO 1999/49858; U.S. Pat. No. 6,277,882; Mrowietz and Asadullah, *Trends Mol Med* 2005, 111(1), 43-48; and Yazdi and Mrowietz, *Clinics Dermatology* 2008, 26, 522-526); asthma and chronic obstructive pulmonary diseases (Joshi et al., WO 2005/023241 and US 2007/0027076); cardiac insufficiency including left ventricular insufficiency, myocardial infarction and angina pectoris (Joshi et al., WO 2005/023241; Joshi et al., US 2007/0027076); mitochondrial and neurodegenerative diseases such as Parkinson's disease, Alzheimer's disease, Huntington's disease, retinopathia pigmentosa and mitochondrial encephalomyopathy (Joshi and Strebel, WO 2002/055063, US 2006/0205659, U.S. Pat. No. 6,509,376, U.S. Pat. No. 6,858,750, and U.S. Pat. No. 7,157,423); transplantation (Joshi and Strebel, WO 2002/055063, US 2006/0205659, U.S. Pat. No. 6,359,003, U.S. Pat. No. 6,509,376, and U.S. Pat. No. 7,157,423; and Lehmann et al., *Arch Dermatol Res* 2002, 294, 399-404); autoimmune diseases (Joshi and Strebel, WO 2002/055063, U.S. Pat. No. 6,509,376, U.S. Pat. No. 7,157,423, and US 2006/0205659) including multiple sclerosis (MS) (Joshi and Strebel, WO

1998/52549 and U.S. Pat. No. 6,436,992; Went and Lieberburg, US 2008/0089896; Schimrigk et al., *Eur J Neurology* 2006, 13, 604-610; and Schilling et al., *Clin Experimental Immunology* 2006, 145, 101-107); ischemia and reperfusion injury (Joshi et al., US 2007/0027076); AGE-induced genome damage (Heidland, WO 2005/027899); inflammatory bowel diseases such as Crohn's disease and ulcerative colitis; arthritis; and others (Nilsson et al., WO 2006/037342 and Nilsson and Muller, WO 2007/042034).

Fumaderm®, an enteric coated tablet containing a salt mixture of monoethyl fumarate and dimethyl fumarate (DMF) which is rapidly hydrolyzed to monomethyl fumarate, regarded as the main bioactive metabolite, was approved in Germany in 1994 for the treatment of psoriasis. Fumaderm® is dosed TID with 1-2 grams/day administered for the treatment of psoriasis. Fumaderm® exhibits a high degree of interpatient variability with respect to drug absorption and food strongly reduces bioavailability. Absorption is thought to occur in the small intestine with peak levels achieved 5-6 hours after oral administration. Significant side effects occur in 70-90% of patients (Brewer and Rogers, *Clin Expt'l Dermatology* 2007, 32, 246-49; and Hoefnagel et al., *Br J Dermatology* 2003, 149, 363-369). Side effects of current FAE therapy include gastrointestinal upset including nausea, vomiting, diarrhea and/or transient flushing of the skin.

Multiple sclerosis (MS) is an autoimmune disease with the autoimmune activity directed against central nervous system (CNS) antigens. The disease is characterized by inflammation in parts of the CNS, leading to the loss of the myelin sheathing around neuronal axons (gradual demyelination), axonal loss, and the eventual death of neurons, oligodendrocytes and glial cells.

Dimethyl fumarate (DMF) is the active component of the experimental therapeutic, BG-12, studied for the treatment of relapsing-remitting MS (RRMS). In a Phase IIb RRMS study, BG-12 significantly reduced gadolinium-enhancing brain lesions. In preclinical studies, DMF administration has been shown to inhibit CNS inflammation in murine and rat EAE. It has also been found that DMF can inhibit astrogliosis and microglial activations associated with EAE. See, e.g., US Published Application No. 2012/0165404.

There are four major clinical types of MS: 1) relapsing-remitting MS (RRMS), characterized by clearly defined relapses with full recovery or with sequelae and residual deficit upon recovery; periods between disease relapses characterized by a lack of disease progression; 2) secondary progressive MS (SPMS), characterized by initial relapsing remitting course followed by progression with or without occasional relapses, minor remissions, and plateaus; 3) primary progressive MS (PPMS), characterized by disease

progression from onset with occasional plateaus and temporary minor improvements allowed; and 4) progressive relapsing MS (PRMS), characterized by progressive disease onset, with clear acute relapses, with or without full recovery; periods between relapses characterized by continuing progression.

Clinically, the illness most often presents as a relapsing-remitting disease and, to a lesser extent, as steady progression of neurological disability. Relapsing-remitting MS (RRMS) presents in the form of recurrent attacks of focal or multifocal neurologic dysfunction. Attacks may occur, remit, and recur, seemingly randomly over many years. Remission is often incomplete and as one attack follows another, a stepwise downward progression ensues with increasing permanent neurological deficit. The usual course of RRMS is characterized by repeated relapses associated, for the majority of patients, with the eventual onset of disease progression. The subsequent course of the disease is unpredictable, although most patients with a relapsing-remitting disease will eventually develop secondary progressive disease. In the relapsing-remitting phase, relapses alternate with periods of clinical inactivity and may or may not be marked by sequelae depending on the presence of neurological deficits between episodes. Periods between relapses during the relapsing-remitting phase are clinically stable. On the other hand, patients with progressive MS exhibit a steady increase in deficits, as defined above and either from onset or after a period of episodes, but this designation does not preclude the further occurrence of new relapses.

Notwithstanding the above, dimethyl fumarate is also associated with significant drawbacks.

For example, dimethyl fumarate is known to cause side effects upon oral administration, such as flushing and gastrointestinal events including, nausea, diarrhea, and/or upper abdominal pain in subjects. *See, e.g., Gold et al., N. Eng. J. Med.*, 2012, 367(12), 1098-1107. Dimethyl fumarate is dosed BID or TID with a total daily dose of about 480 mg to about 1 gram or more.

Further, in the use of a drug for long-term therapy it is desirable that the drug be formulated so that it is suitable for once- or twice-daily administration to aid patient compliance. A dosing frequency of once-daily or less is even more desirable.

Another problem with long-term therapy is the requirement of determining an optimum dose which can be tolerated by the patient. If such a dose is not determined this can lead to a diminution in the effectiveness of the drug being administered.

Accordingly, it is an object of the present invention to provide compounds and/or compositions which are suitable for long-term administration.

It is a further object of the present invention to provide the use of a pharmaceutical active agent in a manner which enables one to achieve a tolerable steady state level for the drug in a subject being treated therewith.

Because of the disadvantages of dimethyl fumarate described above, there continues to be a need to decrease the dosing frequency, reduce side-effects and/or improve the physicochemical properties associated with DMF. There remains, therefore, a real need in the treatment of neurological diseases, such as MS, for a product which retains the pharmacological advantages of DMF but overcomes its flaws in formulation and/or adverse effects upon administration. The present invention addresses these needs.

In another embodiment, any one of Compounds 1 – 133 is converted to the active species, *i.e.*, monomethyl fumarate, upon oral administration more efficiently than dimethyl fumarate. In another embodiment, any one of Compounds 1 – 133 is converted to the active species, *i.e.*, monomethyl fumarate, upon oral administration more efficiently than one or more of the compounds described in US 8,148,414. For example, any one of Compounds 1 – 133 is completely converted to the active species, *i.e.*, monomethyl fumarate, upon oral administration.

For a drug to achieve its therapeutic effect, it is necessary to maintain the required level of blood or plasma concentration. Many drugs, including dimethyl fumarate, must be administered multiple times a day to maintain the required concentration. Furthermore, even with multiple administrations of such a drug per day, the blood or plasma concentrations of the active ingredient may still vary with time, *i.e.*, at certain time points between administrations there are higher concentrations of the active ingredient than at other times. Thus, at certain time points of a 24-hour period, a patient may receive therapeutically

effective amounts of the active ingredient, while at other time points the concentration of the active ingredient in the blood may fall below therapeutic levels. Additional problems with such drugs include that multiple dosing a day often adversely affects patient compliance with the treatment. Therefore, it is desirable to have a drug dosage form wherein the active ingredient is delivered in such a controlled manner that a constant or substantially constant level of blood or plasma concentration of the active ingredient can be achieved by one or at most two dosing per day. Accordingly, the present invention provides controlled-release formulations as described below. In general, such formulations are known to those skilled in the art or are available using conventional methods.

As used herein, “controlled-release” means a dosage form in which the release of the active agent is controlled or modified over a period of time. Controlled can mean, for example, sustained, delayed or pulsed-release at a particular time. For example, controlled-release can mean that the release of the active ingredient is extended for longer than it would be in an immediate-release dosage form, i.e., at least over several hours.

As used herein, “immediate-release” means a dosage form in which greater than or equal to about 75% of the active ingredient is released within two hours, or, more specifically, within one hour, of administration. Immediate-release or controlled-release may also be characterized by their dissolution profiles.

Formulations may also be characterized by their pharmacokinetic parameters. As used herein, “pharmacokinetic parameters” describe the in vivo characteristics of the active ingredient over time, including for example plasma concentration of the active ingredient. As used herein, “ $C_{\max}$ ” means the measured concentration of the active ingredient in the plasma at the point of maximum concentration. “ $T_{\max}$ ” refers to the time at which the concentration of the active ingredient in the plasma is the highest. “AUC” is the area under the curve of a graph of the concentration of the active ingredient (typically plasma concentration) vs. time, measured from one time to another.

The controlled-release formulations provided herein provide desirable properties and advantages. For example, the formulations can be administered once daily, which is particularly desirable for the subjects described herein. The formulation can provide many therapeutic benefits that are not achieved with corresponding shorter acting, or immediate-release preparations. For example, the formulation can maintain lower, more steady plasma peak values, for example,  $C_{\max}$ , so as to reduce the incidence and severity of possible side effects.

Sustained-release dosage forms release their active ingredient into the gastrointestinal tract of a patient over a sustained period of time following administration of the dosage form to the patient. Particular dosage forms include: (a) those in which the active ingredient is embedded in a matrix from which it is released by diffusion or erosion; (b) those in which the active ingredient is present in a core which is coated with a release rate-controlling membrane; (c) those in which the active ingredient is present in a core provided with an outer coating impermeable to the active ingredient, the outer coating having an aperture (which may be drilled) for release of the active ingredient; (d) those in which the active ingredient is released through a semi-permeable membrane, allowing the drug to diffuse across the membrane or through liquid filled pores within the membrane; and (e) those in which the active ingredient is present as an ion exchange complex.

It will be apparent to those skilled in the art that some of the above means of achieving sustained-release may be combined, for example a matrix containing the active compound may be formed into a multiparticulate and/or coated with an impermeable coating provided with an aperture.

Pulsed-release formulations release the active compound after a sustained period of time following administration of the dosage form to the patient. The release may then be in the form of immediate- or sustained-release. This delay may be achieved by releasing the drug at particular points in the gastro-intestinal tract or by releasing drug after a pre-determined time. Pulsed-release formulations may be in the form of tablets or multiparticulates or a combination of both. Particular dosage forms include: (a) osmotic potential triggered release (see U.S. Pat. No. 3,952,741); (b) compression coated two layer tablets (see U.S. Pat. No. 5,464,633); (c) capsules containing an erodible plug (see U.S. Pat. No. 5,474,784); sigmoidal releasing pellets (referred to in U.S. Pat. No. 5,112,621); and (d) formulations coated with or containing pH-dependent polymers including shellac, phthalate derivatives, polyacrylic acid derivatives and crotonic acid copolymers.

Dual release formulations can combine the active ingredient in immediate release form with additional active ingredient in controlled-release form. For example, a bilayer tablet can be formed with one layer containing immediate release active ingredient and the other layer containing the active ingredient embedded in a matrix from which it is released by diffusion or erosion. Alternatively, one or more immediate release beads can be combined with one or more beads which are coated with a release rate-controlling membrane in a capsule to give a dual release formulation. Sustained release formulations in which the active ingredient is present in a core provided with an outer coating impermeable to the active

ingredient, the outer coating having an aperture (which may be drilled) for release of the active ingredient, can be coated with drug in immediate release form to give a dual release formulation. Dual release formulations can also combine drug in immediate release form with additional drug in pulsed release form. For example, a capsule containing an erodible plug could liberate drug initially and, after a predetermined period of time, release additional drug in immediate- or sustained-release form.

In some embodiments, the dosage forms to be used can be provided as controlled-release with respect to one or more active ingredients therein using, for example, hydroxypropylmethyl cellulose, other polymer matrices, gels, permeable membranes, osmotic systems, multilayer coatings, microparticles, liposomes, or microspheres or a combination thereof to provide the desired release profile in varying proportions. Suitable controlled-release formulations known to those of ordinary skill in the art, including those described herein, can be readily selected for use with the pharmaceutical compositions of the invention. Thus, single unit dosage forms suitable for oral administration, such as tablets, capsules, gelcaps, and caplets that are adapted for controlled-release are encompassed by the present invention.

Most controlled-release formulations are designed to initially release an amount of drug that promptly produces the desired therapeutic effect, and gradually and continually release of additional amounts of drug to maintain this level of therapeutic effect over an extended period of time. In order to maintain this constant level of drug in the body, the drug must be released from the dosage form at a rate that will replace the amount of drug being metabolized and excreted from the body.

Controlled-release of an active ingredient can be stimulated by various inducers, for example pH, temperature, enzymes, concentration, or other physiological conditions or compounds.

Powdered and granular formulations of a pharmaceutical preparation of the invention may be prepared using known methods. Such formulations may be administered directly to a subject, used, for example, to form tablets, to fill capsules, or to prepare an aqueous or oily suspension or solution by addition of an aqueous or oily vehicle thereto. Each of these formulations may further comprise one or more of a dispersing agent, wetting agent, suspending agent, and a preservative. Additional excipients, such as fillers, sweeteners, flavoring, or coloring agents, may also be included in these formulations.

A formulation of a pharmaceutical composition of the invention suitable for oral administration may be prepared or packaged in the form of a discrete solid dose unit

including, but not limited to, a tablet, a hard or soft capsule, a cachet, a troche, or a lozenge, each containing a predetermined amount of the active ingredient. In one embodiment, a formulation of a pharmaceutical composition of the invention suitable for oral administration is coated with an enteric coat.

A tablet comprising the active ingredient may, for example, be made by compressing or molding the active ingredient, optionally with one or more additional ingredients. Compressed tablets may be prepared by compressing, in a suitable device, the active ingredient in a free flowing form such as a powder or granular preparation, optionally mixed with one or more of a binder, a lubricant, an excipient, a surface-active agent, and a dispersing agent. Molded tablets may be made by molding, in a suitable device, a mixture of the active ingredient, a pharmaceutically acceptable carrier, and at least sufficient liquid to moisten the mixture. Pharmaceutically acceptable excipients used in the manufacture of tablets include, but are not limited to, inert diluents, granulating and disintegrating agents, binding agents, and lubricating agents. Known dispersing agents include, but are not limited to, potato starch and sodium starch glycollate. Known surface-active agents include, but are not limited to, sodium lauryl sulphate and poloxamers. Known diluents include, but are not limited to, calcium carbonate, sodium carbonate, lactose, microcrystalline cellulose, calcium phosphate, calcium hydrogen phosphate, and sodium phosphate. Known granulating and disintegrating agents include, but are not limited to, corn starch and alginic acid. Known binding agents include, but are not limited to, gelatin, acacia, pre-gelatinized maize starch, polyvinylpyrrolidone, and hydroxypropyl methylcellulose. Known lubricating agents include, but are not limited to, magnesium stearate, stearic acid, silica, and talc.

Tablets may be non-coated or they may be coated using known methods to achieve delayed disintegration in the gastrointestinal tract of a subject, thereby providing sustained release and absorption of the active ingredient. By way of example, a material such as glyceryl monostearate or glyceryl distearate may be used to coat tablets. Further by way of example, tablets may be coated using methods described in U.S. Pat. Nos. 4,256,108; 4,160,452; and 4,265,874 to form osmotically-controlled release tablets, optionally, with laser drilling. Tablets may further comprise a sweetener, a flavoring agent, a coloring agent, a preservative, or some combination of these in order to provide for pharmaceutically elegant and palatable formulations.

Hard capsules comprising the active ingredient may be made using a physiologically degradable composition, such as gelatin or HPMC. Such hard capsules comprise the active

ingredient, and may further comprise additional ingredients including, for example, an inert solid diluent such as calcium carbonate, calcium phosphate, or kaolin.

Soft gelatin capsules comprising the active ingredient may be made using a physiologically degradable composition, such as gelatin. Such soft capsules comprise the active ingredient, which may be mixed with water or an oil medium such as peanut oil, liquid paraffin, or olive oil.

As used herein, “alkyl”, “C<sub>1</sub>, C<sub>2</sub>, C<sub>3</sub>, C<sub>4</sub>, C<sub>5</sub> or C<sub>6</sub> alkyl” or “C<sub>1</sub>-C<sub>6</sub> alkyl” is intended to include C<sub>1</sub>, C<sub>2</sub>, C<sub>3</sub>, C<sub>4</sub>, C<sub>5</sub> or C<sub>6</sub> straight chain (linear) saturated aliphatic hydrocarbon groups and C<sub>3</sub>, C<sub>4</sub>, C<sub>5</sub> or C<sub>6</sub> branched saturated aliphatic hydrocarbon groups. For example, C<sub>1</sub>-C<sub>6</sub> alkyl is intended to include C<sub>1</sub>, C<sub>2</sub>, C<sub>3</sub>, C<sub>4</sub>, C<sub>5</sub> and C<sub>6</sub> alkyl groups. Examples of alkyl include, moieties having from one to six carbon atoms, such as, but not limited to, methyl, ethyl, n-propyl, i-propyl, n-butyl, s-butyl, t-butyl, n-pentyl, s-pentyl, or n-hexyl.

In certain embodiments, a straight chain or branched alkyl has six or fewer carbon atoms (*e.g.*, C<sub>1</sub>-C<sub>6</sub> for straight chain, C<sub>3</sub>-C<sub>6</sub> for branched chain), and in another embodiment, a straight chain or branched alkyl has four or fewer carbon atoms.

As used herein, “alkyl linker” is intended to include C<sub>1</sub>, C<sub>2</sub>, C<sub>3</sub>, C<sub>4</sub>, C<sub>5</sub>, or C<sub>6</sub> straight chain (linear) saturated aliphatic hydrocarbon groups and C<sub>3</sub>, C<sub>4</sub>, C<sub>5</sub>, or C<sub>6</sub> branched saturated aliphatic hydrocarbon groups. For example, C<sub>1</sub>-C<sub>6</sub> alkyl linker is intended to include C<sub>1</sub>, C<sub>2</sub>, C<sub>3</sub>, C<sub>4</sub>, C<sub>5</sub>, and C<sub>6</sub> alkyl linker groups. Examples of alkyl linker include, moieties having from one to six carbon atoms, such as, but not limited to, methyl (-CH<sub>2</sub>-), ethyl (-CH<sub>2</sub>CH<sub>2</sub>-), n-propyl (-CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>-), i-propyl (-CHCH<sub>3</sub>CH<sub>2</sub>-), n-butyl (-CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>-), s-butyl (-CHCH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>-), i-butyl (-C(CH<sub>3</sub>)<sub>2</sub>CH<sub>2</sub>-), n-pentyl (-CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>-), s-pentyl (-CHCH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>-) or n-hexyl (-CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>-). The term “substituted alkyl linker” refers to alkyl linkers having substituents replacing one or more hydrogen atoms on one or more carbons of the hydrocarbon backbone. Such substituents do not alter the sp<sup>3</sup>-hybridization of the carbon atom to which they are attached and include those listed below for “substituted alkyl.”

“Heteroalkyl” groups are alkyl groups, as defined above, that have an oxygen, nitrogen, sulfur or phosphorous atom replacing one or more hydrocarbon backbone carbon atoms.

As used herein, the term “cycloalkyl”, “C<sub>3</sub>, C<sub>4</sub>, C<sub>5</sub>, C<sub>6</sub>, C<sub>7</sub> or C<sub>8</sub> cycloalkyl” or “C<sub>3</sub>-C<sub>8</sub> cycloalkyl” is intended to include hydrocarbon rings having from three to eight carbon atoms in their ring structure. In one embodiment, a cycloalkyl group has five or six carbons in the ring structure.

The term “substituted alkyl” refers to alkyl moieties having substituents replacing one or more hydrogen atoms on one or more carbons of the hydrocarbon backbone. Such substituents can include, for example, alkyl, alkenyl, alkynyl, halogen, hydroxyl, alkylcarbonyloxy, arylcarbonyloxy, alkoxycarbonyloxy, aryloxy carbonyloxy, carboxylate, alkylcarbonyl, arylcarbonyl, alkoxycarbonyl, aminocarbonyl, alkylaminocarbonyl, dialkylaminocarbonyl, alkylthiocarbonyl, alkoxyl, phosphate, phosphonato, phosphinato, amino (including alkylamino, dialkylamino, arylamino, diarylamino, and alkylaryl amino), acylamino (including alkylcarbonylamino, arylcarbonylamino, carbamoyl, and ureido), amidino, imino, sulfhydryl, alkylthio, arylthio, thiocarboxylate, sulfates, alkylsulfanyl, sulfonato, sulfamoyl, sulfonamido, nitro, trifluoromethyl, cyano, azido, heterocyclyl, alkylaryl, or an aromatic or heteroaromatic moiety. Cycloalkyls can be further substituted, *e.g.*, with the substituents described above. An “alkylaryl” or an “aralkyl” moiety is an alkyl substituted with an aryl (*e.g.*, phenylmethyl(benzyl)).

Unless the number of carbons is otherwise specified, “lower alkyl” includes an alkyl group, as defined above, having from one to six, or in another embodiment from one to four, carbon atoms in its backbone structure. “Lower alkenyl” and “lower alkynyl” have chain lengths of, for example, two to six or of two to four carbon atoms.

“Aryl” includes groups with aromaticity, including “conjugated”, or multicyclic, systems with at least one aromatic ring. Examples include phenyl, benzyl, naphthyl, etc. “Heteroaryl” groups are aryl groups, as defined above, having from one to four heteroatoms in the ring structure, and may also be referred to as “aryl heterocycles” or “heteroaromatics”. As used herein, the term “heteroaryl” is intended to include a stable 5-, 6-, or 7-membered monocyclic or 7-, 8-, 9-, 10-, 11- or 12-membered bicyclic aromatic heterocyclic ring which consists of carbon atoms and one or more heteroatoms, *e.g.*, 1 or 1-2 or 1-3 or 1-4 or 1-5 or 1-6 heteroatoms, independently selected from the group consisting of nitrogen, oxygen and sulfur. The nitrogen atom may be substituted or unsubstituted (*i.e.*, N or NR wherein R is H or other substituents, as defined). The nitrogen and sulfur heteroatoms may optionally be oxidized (*i.e.*, N → O and S(O)<sub>p</sub>, where p=1 or 2). It is to be noted that total number of S and O atoms in the heteroaryl is not more than 1.

Examples of heteroaryl groups include pyrrole, furan, thiophene, thiazole, isothiazole, imidazole, triazole, tetrazole, pyrazole, oxazole, isoxazole, pyridine, pyrazine, pyridazine, pyrimidine, and the like.

As used herein, “Ph” refers to phenyl, and “Py” refers to pyridinyl.

In the case of multicyclic aromatic rings, only one of the rings needs to be aromatic (*e.g.*, 2,3-dihydroindole), although all of the rings may be aromatic (*e.g.*, quinoline). The second ring can also be fused or bridged.

The aryl or heteroaryl aromatic ring can be substituted at one or more ring positions with such substituents as described above, for example, alkyl, alkenyl, alkynyl, halogen, hydroxyl, alkoxy, alkylcarbonyloxy, arylcarbonyloxy, alkoxycarbonyloxy, aryloxy, carboxylate, alkylcarbonyl, alkylaminocarbonyl, aralkylaminocarbonyl, alkenylaminocarbonyl, alkylcarbonyl, arylcarbonyl, aralkylcarbonyl, alkenylcarbonyl, alkoxycarbonyl, aminocarbonyl, alkylthiocarbonyl, phosphate, phosphonate, phosphinato, amino (including alkylamino, dialkylamino, arylamino, diarylamino, and alkylarylamino), acylamino (including alkylcarbonylamino, arylcarbonylamino, carbamoyl, and ureido), amidino, imino, sulfhydryl, alkylthio, arylthio, thiocarboxylate, sulfates, alkylsulfinyl, sulfonate, sulfamoyl, sulfonamido, nitro, trifluoromethyl, cyano, azido, heterocyclyl, alkylaryl, or an aromatic or heteroaromatic moiety. Aryl groups can also be fused or bridged with alicyclic or heterocyclic rings, which are not aromatic so as to form a multicyclic system (*e.g.*, tetralin, methylenedioxyphenyl).

As used herein, “carbocycle” or “carbocyclic ring” is intended to include any stable monocyclic, bicyclic or tricyclic ring having the specified number of carbons, any of which may be saturated, unsaturated, or aromatic. For example, a C<sub>3</sub>-C<sub>14</sub> carbocycle is intended to include a monocyclic, bicyclic or tricyclic ring having 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13 or 14 carbon atoms. Examples of carbocycles include, but are not limited to, cyclopropyl, cyclobutyl, cyclobutenyl, cyclopentyl, cyclopentenyl, cyclohexyl, cycloheptenyl, cycloheptyl, cycloheptenyl, adamantyl, cyclooctyl, cyclooctenyl, cyclooctadienyl, fluorenyl, phenyl, naphthyl, indanyl, adamantyl, and tetrahydronaphthyl. Bridged rings are also included in the definition of carbocycle, including, for example, [3.3.0]bicyclooctane, [4.3.0]bicyclononane, [4.4.0]bicyclodecane and [2.2.2]bicyclooctane. A bridged ring occurs when one or more carbon atoms link two non-adjacent carbon atoms. In one embodiment, bridge rings are one or two carbon atoms. It is noted that a bridge always converts a monocyclic ring into a tricyclic ring. When a ring is bridged, the substituents recited for the ring may also be

present on the bridge. Fused (e.g., naphthyl, tetrahydronaphthyl) and spiro rings are also included.

As used herein, “heterocycle” includes any ring structure (saturated or partially unsaturated) which contains at least one ring heteroatom (e.g., N, O or S). When a substituent is keto (*i.e.*, =O), then 2 hydrogen atoms on the atom are replaced. Keto substituents are not present on aromatic moieties. Ring double bonds, as used herein, are double bonds that are formed between two adjacent ring atoms (*e.g.*, C=C, C=N or N=N). “Stable compound” and “stable structure” are meant to indicate a compound

that is sufficiently robust to survive isolation to a useful degree of purity from a reaction mixture, and formulation into an efficacious therapeutic agent.

The term “acyl”, as used herein, includes moieties that contain the acyl radical (–C(O)–) or a carbonyl group. “Substituted acyl” includes acyl groups where one or more of the hydrogen atoms are replaced by, for example, alkyl groups, alkynyl groups, halogen, hydroxyl, alkylcarbonyloxy, arylcarbonyloxy, alkoxy carbonyloxy, aryloxy carbonyloxy, carboxylate, alkylcarbonyl, arylcarbonyl, alkoxy carbonyl, aminocarbonyl, alkylaminocarbonyl, dialkylaminocarbonyl, alkylthiocarbonyl, alkoxy, phosphate, phosphonato, phosphinato, amino (including alkylamino, dialkylamino, arylamino, diarylamino and alkylarylamino), acylamino (including alkylcarbonylamino, arylcarbonylamino, carbamoyl and ureido), amidino, imino, sulfhydryl, alkylthio, arylthio, thiocarboxylate, sulfates, alkylsulfinyl, sulfonato, sulfamoyl, sulfonamido, nitro, trifluoromethyl, cyano, azido, heterocyclyl, alkylaryl, or an aromatic or heteroaromatic moiety.

It is also to be understood that all of the compounds of the invention described above will further include bonds between adjacent atoms and/or hydrogens as required to satisfy the valence of each atom. That is, bonds and/or hydrogen atoms are added to provide the following number of total bonds to each of the following types of atoms: carbon: four bonds; nitrogen: three bonds; oxygen: two bonds; and sulfur: two-six bonds.

As used herein, a “subject in need thereof” is a subject having a neurological disease. In one embodiment, a subject in need thereof has multiple sclerosis. A “subject” includes a mammal. ## EXPERIMENTAL

### General Procedure 1

To a mixture of monomethyl fumarate (MMF) (1.0 equivalent) and HBTU (1.5 equivalents) in DMF (25 ml per g of MMF) was added Hünigs base (2.0 equivalents). The dark brown solution was stirred for 10 minutes, where turned into a brown suspension, before addition of the alcohol (1.0 – 1.5 equivalents). The reaction was stirred for 18 hours at room temperature. Water was added and the product extracted into ethyl acetate three times. The combined organic layers were washed with water three times, dried with magnesium sulphate, filtered and concentrated in vacuo at 45 °C to give the crude product. The crude product was purified by silica chromatography and in some cases further purified by trituration with diethyl ether to give the clean desired ester product. All alcohols were either commercially available or made following known literature procedures.

#### General Procedure 2- Conversion of the Ester Product into the Hydrochloride Salt

To a mixture of the ester product in diethyl ether (25 ml per g) was added 2M HCl in diethyl ether (1.5 equivalents). The mixture was stirred at room temperature for two hours. The solvent was decanted, more diethyl ether added and the solvent decanted again. The remaining mixture was then concentrated in vacuo at 45 °C and further dried in a vacuum oven at 55 °C for 18 hours to give the solid HCl salt.

#### General Procedure 3

To a 100 mL, one-necked, round-bottomed flask, fitted with a magnetic stirrer and nitrogen inlet/outlet, were added 11 mL of an MTBE solution containing freshly prepared mono-methyl fumaryl chloride (4.9 g, 33 mmol) and 50 mL of additional MTBE at 20 °C. The resulting yellow solution was cooled to <20 °C with an ice water bath. Then, the alcohol, (33 mmol, 1 eq) was added dropwise, via syringe, over approximately 10 minutes. The reaction mixture was allowed to stir at <20 °C for 10 minutes after which time the cooling bath was removed and the reaction was allowed to warm to 20 °C and stir at 20 °C temperature for 16 hours. The reaction was deemed complete by TLC after 16 hours at RT. The reaction mixture was filtered through a medium glass fritted funnel to collect the off-white solids. The solids were dried in a vacuum oven at 25 °C overnight to afford the final product as an HCl salt. All alcohols were either commercially available or made following known literature procedures.

#### General Procedure 4- Alkylation with an Appropriate Alkyl Mesylate

A mixture of monomethyl fumarate (MMF) (1.3 equivalent), the alkyl mesylate (1 equivalent), and potassium carbonate (1.5 equivalent) in acetonitrile (50 ml per g of MMF) was heated at reflux overnight. The mixture was partitioned between ethyl acetate and saturated aqueous sodium hydrogen carbonate, and the organic phase dried (MgSO<sub>4</sub>). Filtration and removal of the solvent under reduced pressure gave the crude product which was purified in each case by silica chromatography.

### General Procedure 5- Alkylation with an Appropriate Alkyl Chloride

A mixture of monomethyl fumarate (MMF) (1.3 equivalent), the alkyl chloride (1 equivalent), and potassium carbonate (1.5 equivalent) in acetonitrile or dimethylformamide (50 ml per g of MMF) was heated at 20 to 65 °C overnight. The mixture was partitioned between ethyl acetate and saturated aqueous sodium hydrogen carbonate, and the organic phase dried (MgSO<sub>4</sub>). Filtration and removal of the solvent under reduced pressure gave the crude product which was further purified by silica chromatography.

To a suspension of monomethyl fumarate (MMF) (1.0 equivalent) in dichloromethane (11 ml per g of MMF) was added diisopropylethylamine (3 equivalents), the desired alcohol (1.02 equivalents) and *N,N,N',N'*-tetramethyl-*O*-(1*H*-benzotriazol-1-yl)uronium tetrafluoroborate (1.5 equivalents). The reaction was stirred for 1-18 hours at <10 °C. The reaction was quenched with 1M hydrochloric acid (0.6 mL/mL of DCM). The organic layer was washed with 10% (w/w) aqueous sodium bicarbonate solution (0.6 mL/mL of DCM) followed by 37% (w/w) sodium chloride solution (0.6 mL/mL of DCM). The organic layer was dried over sodium sulfate, filtered to remove the drying agent, and the solution added to a silica plug (~6 g of silica gel/g of MMF) and the plug flushed with DCM until no more

product eluted. ~80% of the DCM was removed under reduced pressure at 30 °C after which time 25 mL of MTBE/g of MMF were added and the solution further concentrated at 30 °C until ~10 mL/g of MMF remained. The resulting suspension was cooled to 5 °C for at least 1 hour and then the resulting solids were collected by filtration to give the desired MMF ester prodrug. (2.4 g, 67 %).

#### Example 2- Aqueous Chemical Stability of Several Compounds

Stock solutions of the compounds in acetonitrile or acetonitrile/methanol were prepared at 20 mg/mL and 20 µL, spiked into 3mL of buffer phosphate (100mM) and incubated at 37 °C. Aliquots (50 µL) were sampled at different time points and diluted 20 fold with ammonium formate (pH 3.5)/acetonitrile. The diluted samples were analyzed by HPLC. The peak areas corresponding to the compounds were plotted against time and the data were fitted to a first-order mono-exponential decay where the rate constant and the half-life were determined (Table 3). In some cases, in which the half life is too long (>360min), an estimated value of the half life is reported using the initial slope at low conversion (<10%).

#### Example 3- Evaluation of Aqueous Chemical Stability with NMR

The chemical hydrolysis was followed by dissolving the ester in phosphate buffered D<sub>2</sub>O (pH 7.9) in an NMR tube, heating the NMR tube to 37° C and periodically recording the spectra. These various species produced by hydrolysis of the diesters were followed over time. See Figures 1-5.

#### Example 4- Delivery of MMF in Rats Upon Oral Administration of Prodrugs

Rats were obtained commercially and were pre-cannulated in the jugular vein. Animals were conscious at the time of the experiment. All animals were fasted overnight and until 4 hours post-dosing of a prodrug in the disclosure.

Blood samples (0.25 mL/sample) were collected from all animals at different time-points up to 24 hours post-dose into tubes containing sodium fluoride/sodium EDTA. Samples were centrifuged to obtain plasma. Plasma samples were transferred to plain tubes and stored at or below -70° C prior to analysis.

To prepare analysis standards, 20 uL of rat plasma standard was quenched with 60 uL of internal standard. The sample tubes were vortexed for at least 1 min and then centrifuged at 3000 rpm for 10 min. 50 uL of supernatant was then transferred to 96-well plates containing 100 µL water for analysis by LC-MS-MS.

LC-MS/MS analysis was performed using an API 4000 equipped with HPLC and autosampler. The following HPLC column conditions were used: HPLC column: Waters Atlantis T3; flow rate 0.5 mL/min; run time 5 min; mobile phase A: 0.1% formic acid in water; mobile phase B: 0.1% formic acid in acetonitrile (ACN); gradient: 98% A/2% B at 0.0 min; 98% A/2% B at 1 min; 5% A/95% B at 3 min; 5% A/95% B at 3.75 min; 97% A/3% B at 4 min; and 98% A/2% B at 5.0 min. MMF was monitored in positive ion mode.

MMF, DMF or MMF prodrug was administered by oral gavage to groups of two to six adult male Sprague-Dawley rats (about 250 g). Animals were conscious at the time of the experiment. MMF, DMF or MMF prodrug was orally administered in an aqueous solution of 0.5% hydroxypropyl methyl cellulose (HPMC), 0.02% polysorbate 80, and 20 mM citrate buffer (pH 5), at a dose of 10 mg-equivalents MMF per kg body weight.

The percent absolute bioavailability (F%) of MMF was determined by comparing the area under the MMF concentration vs time curve (AUC) following oral administration of MMF, DMF or MMF prodrug with the AUC of the MMF concentration vs time curve following intravenous administration of MMF on a dose normalized basis.

The MMF prodrugs, when administered orally to rats at a dose of 10 mg/kg MMF-equivalents in the aqueous vehicle, exhibited an absolute oral bioavailability (relative to IV) ranging from about 3% to about 96% (See Tables 5 and 6). Tables 5 and 6 show data from two independent studies.

#### Example 5- Delivery of MMF in Dogs Upon Oral Administration of Prodrugs

Male Beagle dogs were obtained from the test facility's colony of non-native animals. All animals were fasted overnight prior to dose administration.

Oral doses were administered via oral gavage. The gavage tube was flushed with 10 mL of water prior to removal.

All animals were observed at dosing and at each scheduled collection. All abnormalities were recorded.

Blood samples were collected in Sodium Fluoride/Na<sub>2</sub>EDTA tubes and stored on wet ice until processed to plasma by centrifugation (300 rpm at 5°C) within 30 minutes of collection. All plasma samples were transferred into separate 96-well plates (matrix tubes) and stored at -80 °C until concentration analysis was performed via LC/MS/MS using an RGA 3 assay.

#### Extraction Procedure:

Note: Thawed test samples at 4°C. (Kept in ice while on bench).

1. Aliquoted 20uL of study sample, standard, and QC samples into labeled 96-well plate.
2. Added 120uL of appropriate internal standard solution (125ng/mL mouse embryo fibroblasts (MEF)) to each tube, except for the double blank to which 120uL of appropriate acetonitrile:FA (100:1) was added.
3. Sealed and vortexed for one minute.
4. Centrifuged at 3000 rpm for 10 minutes.
5. Transferred 100uL of supernatant to a clean 96-well plate containing 100uL water.
6. Sealed and vortexed gently for 2 minutes.

The percent absolute bioavailability (F%) of MMF was determined by comparing the area under the MMF concentration vs time curve (AUC) following oral administration of MMF prodrug with the AUC of the MMF concentration vs time curve following intravenous administration of MMF on a dose normalized basis.

The MMF prodrugs, when administered orally to dogs at a dose of 10 mg/kg MMF-equivalents in the aqueous vehicle, exhibited an absolute oral bioavailability (relative to IV) ranging from about 31% to about 78% (See Table 7).

#### Example 6- Physical Stability of the Instant Prodrugs and DMF in Crystalline Form

The physical stability of compounds of the present invention and DMF were measured via thermogravimetric analysis (TGA). Figure 6 shows a plot of weight loss at 60 °C vs time for Compound 14 (12.15 mg), no change, and DMF (18.40 mg), ~100 % weight loss in less than 4 hours. These data indicate that DMF undergoes sublimation while Compound 14 is physically stable under similar conditions.
