

TRICYCLIC TRIAZOLIC COMPOUNDS

5 FIELD OF THE INVENTION

The present invention relates to new tricyclic triazolic compounds having a great affinity for sigma receptors, especially sigma-1 receptors, as well as to the process for the preparation thereof, to compositions comprising them, and to their use as medicaments.

BACKGROUND OF THE INVENTION

The search for new therapeutic agents has been greatly aided in recent years by better understanding of the structure of proteins and other biomolecules associated with target diseases. One important class of these proteins are the sigma (σ) receptors, cell surface receptors of the central nervous system (CNS) which may be related to the dysphoric, hallucinogenic and cardiac stimulant effects of opioids. From studies of the biology and function of sigma receptors, evidence has been presented that sigma receptor ligands may be useful in the treatment of psychosis and movement disorders such as dystonia and tardive dyskinesia, and motor disturbances associated with Huntington's chorea or Tourette's syndrome and in Parkinson's disease (Walker, J.M. et al, Pharmacological Reviews, 1990, 42, 355). It has been reported that the known sigma receptor ligand rimcazole clinically shows effects in the treatment of psychosis (Snyder, S.H., Largent, B.L. J. Neuropsychiatry 1989, 1, 7). The sigma binding sites have preferential affinity for the dextrorotatory isomers of certain opiate benzomorphans, such as (+)-SKF 10047, (+)cyclazocine, and (+)-pentazocine and also for some narcoleptics such as haloperidol.

"The sigma receptor/s" as used in this application is/are well known and defined using the following citation: This binding site represents a typical protein different from opioid, NMDA, dopaminergic, and other known neurotransmitter or hormone receptor families (G. Ronsisvalle et al. Pure Appl. Chem. 73, 1499-1509 (2001)).

The sigma receptor has at least two subtypes, which may be discriminated by stereoselective isomers of these pharmacologically active drugs. SKF 10047 has nanomolar

affinity for the sigma 1 (σ -1) site, and has micromolar affinity for the sigma 2 (σ -2) site. Haloperidol has similar affinities for both subtypes.

5 The Sigma-1 receptor is a non-opiaceous type receptor expressed in numerous adult mammal tissues (e.g. central nervous system, ovary, testicle, placenta, adrenal gland, spleen, liver, kidney, gastrointestinal tract) as well as in embryo development from its earliest stages, and is apparently involved in a large number of physiological functions. Its high affinity for various pharmaceuticals has been described, such as for SKF-10047, (+)-pentazocine, haloperidol and rimcazole, among others, known ligands with analgesic, anxiolytic, antidepressive, 10 antiamnesic, antipsychotic and neuroprotective activity. Sigma-1 receptor is of great interest in pharmacology in view of its possible physiological role in processes related to analgesia, anxiety, addiction, amnesia, depression, schizophrenia, stress, neuroprotection and psychosis [Kaiser et al (1991) Neurotransmissions 7 (1): 1-5], [Walker, J.M. et al, Pharmacological Reviews, 1990, 42, 355] and [Bowen W.D. 15 (2000) Pharmaceutica Acta Helvetiae 74: 211-218].

The Sigma-2 receptor is also expressed in numerous adult mammal tissues (e.g. nervous system, immune system, endocrine system, liver, kidney). Sigma-2 20 receptors can be components in a new apoptosis route that may play an important role in regulating cell proliferation or in cell development. This route seems to consist of Sigma-2 receptors joined to intracellular membranes, located in organelles storing calcium, such as the endoplasmic reticulum and mitochondria, which also have the ability to release calcium from these organelles. The calcium 25 signals can be used in the signaling route for normal cells and/or in induction of apoptosis.

Agonists of Sigma-2 receptors induce changes in cell morphology, apoptosis in several types of cell lines and regulate the expression of p-glycoprotein mRNA, so 30 that they are potentially useful as antineoplastic agents for treatment of cancer. In fact, Sigma-2 receptor agonists have been observed to induce apoptosis in mammary tumour cell lines resistant to common antineoplastic agents that damage DNA. In addition, agonists of Sigma-2 receptors enhance the cytotoxic effects of these antineoplastic agents at concentrations in which the agonist is not cytotoxic.

Thus, agonists of Sigma-2 receptors can be used as antineoplastic agents at doses inducing apoptosis or at sub-toxic doses in combination with other antineoplastic agents to revert the resistance to the drug, thereby allowing using lower doses of the antineoplastic agent and considerably reducing its adverse effects.

5

Antagonists of Sigma-2 receptors can prevent the irreversible motor side effects caused by typical neuroleptic agents. In fact, it has been found that antagonists of Sigma-2 receptors can be useful as agents for improving the weakening effects of delayed dyskinesia appearing in patients due to chronic treatment of psychosis with typical antipsychotic drugs, such as haloperidol. Sigma-2 receptors also seem to play a role in certain degenerative disorders in which blocking these receptors could be useful.

10

Endogenous sigma ligands are not known, although progesterone has been suggested to be one of them. Possible sigma-site-mediated drug effects include modulation of glutamate receptor function, neurotransmitter response, neuroprotection, behavior, and cognition (Quirion, R. et al. Trends Pharmacol. Sci., 1992, 13:85-86). Most studies have implied that sigma binding sites (receptors) are plasmalemmal elements of the signal transduction cascade. Drugs reported to be selective sigma ligands have been evaluated as antipsychotics (Hanner, M. et al. Proc. Natl. Acad. Sci., 1996, 93:8072-8077). The existence of sigma receptors in the CNS, immune and endocrine systems have suggested a likelihood that it may serve as link between the three systems.

15

20

25

In view of the potential therapeutic applications of agonists or antagonists of the sigma receptor, a great effort has been directed to find selective ligands. Thus, the prior art discloses different sigma receptor ligands.

30

For instance, the international patent application WO2007/098961 describes 4,5,6,7 tetrahydrobenzo[b]thiophene derivatives having pharmacological activity towards the sigma receptor.

Spiro[benzopyran] or spiro[benzofuran] derivatives were also disclosed in EP1847542 as well as pyrazole derivatives (EP1634873) with pharmacological activity on sigma receptors.

5 WO2009/071657 discloses some tricyclic triazolic compounds although structurally different to the ones of the current invention with activity towards sigma receptors.

10 Nevertheless, there is still a need to find compounds having pharmacological activity towards the sigma receptor, being both effective and selective, and having good "drugability" properties, i.e. good pharmaceutical properties related to administration, distribution, metabolism and excretion.

15 Surprisingly, the authors of the present invention have observed that the new tricyclic triazolic compounds with general formula (I) show an affinity for Sigma receptor ranging from good to excellent. These compounds are therefore particularly suitable as pharmacologically active agents in medicaments for the prophylaxis and/or treatment of disorders or diseases related to Sigma receptors.

20 SUMMARY OF THE INVENTION

The present invention discloses novel compounds with great affinity to sigma receptors and having high solubility in a physiological media which might be used for the treatment of sigma related disorders or diseases.

25 Specifically, it is an object of the present invention novel tricyclic triazolic compounds of general formula (I):

The term “condensed” according to the present invention means that a ring or ring-system is attached to another ring or ring-system, whereby the terms “annulated” or “annelated” are also used by those skilled in the art to designate this kind of attachment.

The term “ring system” according to the present invention refers to ring systems comprising saturated, unsaturated or aromatic carbocyclic ring systems which contain optionally at least one heteroatom as ring member and which are optionally at least mono-substituted. Said ring systems may be condensed to other carbocyclic ring systems such as aryl groups, naphthyl groups, heteroaryl groups, cycloalkyl groups, etc.

The term “salt” is to be understood as meaning any form of the active compound according to the invention in which this assumes an ionic form or is charged and is coupled with a counter-ion (a cation or anion) or is in solution. By this are also to be understood complexes of the active compound with other molecules and ions, in particular complexes which are complexed via ionic interactions. The definition particularly includes physiologically acceptable salts, this term must be understood as equivalent to “pharmacologically acceptable salts”.

The term “pharmaceutically acceptable salts” in the context of this invention means any salt that is tolerated physiologically (normally meaning that it is not toxic, particularly as a result of the counter-ion) when used in an appropriate manner for a treatment, particularly applied or used in humans and/or mammals. These physiologically acceptable salts may be formed with cations or bases and, in the context of this invention, are understood to be salts formed by at least one compound used in accordance with the invention – normally an acid (deprotonated) – such as an anion and at least one physiologically tolerated cation, preferably

inorganic, particularly when used on humans and/or mammals. Salts with alkali and alkali earth metals are particularly preferred, as well as those formed with ammonium cations (NH_4^+). Preferred salts are those formed with (mono) or (di)sodium, (mono) or (di)potassium, magnesium or calcium. These physiologically acceptable salts may also be formed with anions or acids and, in the context of this invention, are understood as being salts formed by at least one compound used in accordance with the invention – normally protonated, for example in nitrogen – such as a cation and at least one physiologically tolerated anion, particularly when used on humans and/or mammals. This definition specifically includes in the context of this invention a salt formed by a physiologically tolerated acid, i.e. salts of a specific active compound with physiologically tolerated organic or inorganic acids – particularly when used on humans and/or mammals. Examples of this type of salts are those formed with: hydrochloric acid, hydrobromic acid, sulphuric acid, methanesulfonic acid, formic acid, acetic acid, oxalic acid, succinic acid, malic acid, tartaric acid, mandelic acid, fumaric acid, lactic acid or citric acid.

The term “prodrug” is used in its broadest sense and encompasses those derivatives that are converted in vivo to the compounds of the invention. Such derivatives would readily occur to those skilled in the art, and include, depending on the functional groups present in the molecule and without limitation, the following derivatives of the compounds of the invention: esters, amino acid esters, phosphate esters, metal salts sulfonate esters, carbamates, and amides. Examples of well known methods of producing a prodrug of a given acting compound are known to those skilled in the art and can be found e.g. in Krogsgaard-Larsen et al. “Textbook of Drug design and Discovery” Taylor & Francis (april 2002).

patient (e.g., by allowing an orally administered compound to be more readily absorbed into the blood) or which enhance delivery of the parent compound to a biological compartment (e.g., the brain or lymphatic system) relative to the parent species.

In another aspect, the invention refers to the processes for obtaining the compounds of general formula (I). Several procedures have been developed for obtaining all the compounds of the invention, and the procedures will be explained below in methods A, B and C.

The obtained reaction products may, if desired, be purified by conventional methods, such as crystallization and chromatography. Where the processes described below for the preparation of compounds of the invention give rise to mixtures of stereoisomers, these isomers may be separated by conventional techniques such as preparative chromatography. If there are chiral centers the compounds may be prepared in racemic form, or individual enantiomers may be prepared either by enantiospecific synthesis or by resolution.

METHOD A

Method A represents a first process for synthesizing compounds according to general formula (I). Method A allows for the preparation of compounds of general formula (Ia) and (Ib) that is compounds of formula (I) where Z represents either a -CH₂- or a C=O.

In this sense, a process is presented for the preparation of a compound of general formula (I):

5

comprising the cycloaddition reaction of a compound of general formula (II) or its enantiomers:

10

wherein **R₁**, **R₂**, **R₃**, **Z** and **n** are as above for general formula (I).

15

The cycloaddition reaction of compound (II) is preferably carried out in an apolar solvent such as, for instance, xylene or toluene. The temperature used in the reaction is preferably in the range from room temperature to reflux.

20

Scheme 1 is a representation of the cycloaddition reaction for the case where **Z** represents a -CH₂- or C=O giving rise to compounds (Ia) and (Ib) respectively.

Scheme 1

5

As represented in scheme 1 compounds of general formula (Ib) can also be obtained by reduction of compounds of general formula (Ia). This reduction reaction is preferably carried out in an aprotic solvent such as tetrahydrofuran (THF) in the presence of a reducing agent such as LiAlH₄ or BH₃ at a temperature ranging from room temperature to solvent reflux temperature

10

METHOD B

Method B represents an alternative way to method A for preparing compounds of general formula (I).

15

In this sense, a process is described for the preparation of a compound of general formula (I):

comprising the reaction in an organic solvent of a compound of general formula (Ic):

5

with a compound of general formula (IIIa) or (VIa):

10

wherein **R₁**, **R₂**, **R₃**, **Z** and **n** are as defined above for formula (I) and X is a suitable leaving group, such as a halogen or sulfonate.

15

When compound (Ic) is reacted with (IIIa) the reaction is preferably carried out in the presence of a base such as diisopropylethylamine (DIPEA), triethylamine or NaH, in an organic solvent such as dichloromethane (DCM), THF or DMF.

On the alternative the reaction of compound (Ic) with a carbonyl derivative (VIa) is carried out in the presence of a reduction agent such as NaBH(OAc)₃, in a organic solvent such as dichloroethane (DCE). In some cases additionally the reaction can

be carried out in the presence of a base such as DIPEA or TEA, or alternatively in the presence of an acid, preferably acetic acid. The type of carbonyl derivative of formula (VIa) to be used will depend on the meaning of the final substituent R_1 desired. For instance, if R_1 is intended to represent a methyl group, formaldehyde should be used in the reaction, if an ethyl group is desired in the position R_1 acetaldehyde should be used etc.

Compounds of formula (I) where R_1 is a benzyl (Bn) can be converted to compounds of formula (Ic) ($R_1=H$). This conversion can be accomplished by reaction of compounds of formula (I) with ammonium formate in the presence of a catalyst such as Pd in carbon and in a polar solvent, such as methanol. The reaction temperature should be between 20 °C to 75 °C. Alternatively, deprotection can be done by hydrogenation with hydrogen also preferably in the presence of a catalyst such as Pd in carbon and in a polar solvent, such as methanol. The reaction can also be done in the additional presence of an acid preferably HCl.

The reactions of method B are represented in scheme 2

Scheme 2

METHOD C

Method C represents an additional process for synthesizing compounds according to general formula (I).

In this sense, a process is described for the preparation of a compound of general formula (I):

5 comprising the reaction in an organic solvent of a compound of general formula (Id):

with a compound of general formula (IIIb), (IV), (V) or (VIb):

10 wherein **R₁**, **R₂**, **R₃**, **Z** and **n** are as defined above for formula (I), R' stands for R₅ or R₆ as defined above for formula (I) and X is a suitable leaving group, such as a halogen or sulfonate.

15 When compound (Id) is reacted with (IIIb), (IV) or (V) the reaction is preferably carried out in the presence of a base such as diisopropylethylamine (DIPEA), triethylamine (TEA) or NaH, in an organic solvent such as dichloromethane (DCM), THF or DMF.

On the alternative the reaction of compound (Id) with an carbonyl derivative (VIb) is carried out in the presence of a reduction agent such as $\text{NaBH}(\text{OAc})_3$, in a organic solvent such as dichloroethane (DCE). In some cases additionally the reaction can be carried out in the presence of a base such as DIPEA or TEA, or alternatively in the presence of an acid, preferably acetic acid. The type of carbonyl derivative of formula (VIb) to be used will depend on the meaning of the final substituent R_3 desired. For instance, if R_3 is intended to represent a methyl group, formaldehyde should be used in the reaction, if an ethyl group is desired in the position R_3 acetaldehyde should be used etc.

Compounds of formula (I) where R_3 is a tertbutoxycarbonyl (Boc) can be converted to compounds of formula (Id) ($\text{R}_3=\text{H}$) by reaction with an acid preferably HCl or trifluoroacetic acid.

The reactions of method C are represented in scheme 3:

In this sense, compounds of general formula (II) encompass compounds of general formula (IIa) and (IIb):

where R_1 , R_2 , R_3 and n have the meaning as defined above for formula (I).

Scheme 4a below represents the reaction for preparing compounds of formula (IIa) or its enantiomers. As observed compound (IIa) can be prepared by the reaction of a compound of formula (VII) or its enantiomers with a carboxylic acid (VIII) in the presence of a coupling activating agent, preferably N-(3-dimethylaminopropyl)-N'-ethylcarbodiimide hydrochloride (EDC), a coupling additive, preferably 1-hydroxybenzotriazole (HOBt) and in the presence of a base, preferably DIPEA or TEA. The reaction takes place in an organic solvent, such as DCM.

Scheme 4a

As an alternative, compounds of formula (IIb) can be prepared by reaction of a compound

of formula (X) or its enantiomers with a compound of formula (XI), where X is a suitable leaving group as halogen or sulfonate, in the presence of a base, preferably NaH. The reaction is carried out in an organic solvent, such as DMF or THF, at a temperature range of room temperature to solvent reflux temperature.

5

Scheme 4b

A compound of formula (IX) can be prepared by the reaction of an epoxide of formula (XII) with an amine (XIII), preferably in the presence of a catalyst, such as $LiClO_4$, in a polar solvent, such as acetonitrile (ACN), at a temperature range of room temperature to solvent reflux temperature.

20

Alternatively, intermediates of general formula (IX) or its enantiomers can be prepared by reaction of an aminoalcohol of formula (XIV) or its enantiomers with a compound of formula (XI), where X is a suitable leaving group, such as halogen or sulfonate, in the presence of a base, preferably K_2CO_3 . The reaction is carried out in

a polar solvent, such as ACN, at a temperature range of room temperature to solvent reflux temperature.

In a further alternative, compounds of formula (IX) can be prepared by reaction with an aldehyde (XV), in the presence of a reduction agent, preferably $\text{NaBH}(\text{OAc})_3$. The reaction is carried out in an organic solvent, preferably DCE and in some cases, additionally in the presence of a base, such as DIPEA or TEA. The reaction between (IX) and (XV) can alternatively be carried out in the presence of NaBH_4 in a polar solvent, preferably MeOH, at a temperature range of room temperature to solvent reflux temperature.

Scheme 5

BIOLOGICAL ACTIVITY

5 Pharmacological study

Brain membrane preparation and binding assays for the σ_1 -receptor were performed as described (DeHaven-Hudkins, D. L., L.C. Fleissner, and F. Y. Ford-Rice, 1992, Characterization of the binding of [^{3} H](+)-pentazocine to σ recognition sites in guinea pig brain, Eur. J. Pharmacol. 227, 371-378) with some modifications.

10 Guinea pig brains were homogenized in 10 vols. (w/v) of Tris-HCl 50 mM 0.32 M sucrose, pH 7.4, with a Kinematica Polytron PT 3000 at 15000 r.p.m. for 30 s. The homogenate was centrifuged at 1000g for 10 min at 4°C and the supernatants collected and centrifuged again at 48000g for 15 min at 4°C. The pellet was resuspended in 10 volumes of Tris-HCl buffer (50 mM, pH 7.4), incubated at 37°C

15 for 30 min, and centrifuged at 48000g for 20 min at 4°C. Following this, the pellet was resuspended in fresh Tris-HCl buffer (50 mM, pH 7.4) and stored on ice until use.

20 The radioligand used was [^{3} H](+)-pentazocine at 5.0 nM and the final volume was 200 μ l. The incubation was initiated with the addition of 100 μ l of membrane at a final tissue concentration of approximately 5 mg tissue net weight/mL and the incubation time was 150 m. at 37 °C. After incubation, the membranes were collected onto pretreated glass fiber filterplate (MultiScreen-FC, Millipore), with polyethylenimine 0.1 %. The filters were washed two times with 200 μ l of washing

25 buffer (50 mM Tris Cl, pH = 7.4) and then 25 μ l of Ecoscint H liquid scintillation

cocktail were added. Microplates were allowed to set for several hours and then quantified by liquid scintillation spectrophotometry (1450 Microbeta, Wallac). Nonspecific binding was determined with 1 μ M haloperidol.

5 The results obtained for the examples are shown in table II.
