

SPECIFICATIONTHIS SHEET HAS BEEN
REPLACEDCIRCUIT CARD CONNECTOR
UTILIZING FLEXIBLE FILM CIRCUITRYBackground of the Invention

The present invention relates generally to edge card connectors, and more particularly to circuit card connectors which utilize flexible circuitry as the contacts of the connector and which have an improved card engagement means.

Connectors are well known in the art which provide a connection between a primary circuit board, or "motherboard" and a secondary circuit board or "daughterboard." The connections between these two printed circuit boards typically occur along an edge the secondary circuit board, and hence such secondary circuit boards are commonly referred to in the art as edge cards.

Such circuit connectors typically include an insulative housing having a printed circuit card-receiving slot extending lengthwise within the connector, and a plurality of flexible conductive contacts which are located on opposing sides of the card-receiving slot. These contacts are typically stamped and formed. In an effort to further reduce the size of electronic components, connectors have been reduced in size and the "pitch" of connectors, i.e., the spacing between the connector contacts, has become smaller. The stamping and forming manufacturing process imposes limitations on the pitch which occurs between the contacts and therefore limits the number of circuits which the connector may accommodate. Currently, minimum pitches of about 0.5mm are obtainable using stamped and formed contacts. This minimum pitch limits the amount of circuits for such a connector.

It has been found that using flexible circuitry for edge card connectors provides numerous advantages.

First, much smaller pitches may be utilized, such as on the order of about 0.3mm. This reduced pitch permits an even greater reduction in the size of the connectors. Second, flexible circuitry provides certain benefits to signal performance, especially with high speed signals. For example, by using conventional coplanar, microstrip or stripline configurations that are readily achievable with flexible circuitry, faster signal rise times and higher signal frequencies may be accomplished. Through the control of the dielectric materials, material thicknesses and circuit positioning parameters, it is possible to achieve improved impedance matching, lower propagation delays as well as a reduction in reflection and crosstalk.

Flexible circuitry has been incorporated in some edge card connectors, such as those shown in U.S. Patent No. 3,614,707 issued October 19, 1971 and U.S. Patent No. 5,427,533 issued January 27, 1995. Both of these connectors have a formed connector housing with a longitudinal slot and a length of flexible circuitry extending over the connector slot such that the flexible circuitry depends into the connector slot. The user inserts the circuit card into the connector slot and forces the circuit card to the bottom of the slot, forcing the edge of the circuit card against the flexible film circuitry. Repeated insertions and removals of the circuit card may impart detrimental stress to the contacts on the flexible circuitry. Additionally, these connectors require springs of complex shape behind the flexible circuitry to ensure reliable contact with the circuit card which leads to increased manufacturing costs.

The present invention is therefore directed to a circuit card connector utilizing flexible circuitry which avoids the imposition of detrimental stress on the flexible circuitry and which provides a reliable circuit

card-engaging means to apply a reliable contact force to the circuit card.

One object of the present invention is to provide an improved circuit card connector which utilizes
5 flexible circuitry as the connector contacts and which utilizes an improved circuit card-engagement assembly.

Another object of the present invention is to provide a circuit card connector having two opposing end portions formed from an insulative material and a circuit
10 card engaging assembly supported between the connector end portions, wherein the circuit card engaging assembly includes opposing, spaced-apart spring members which extend lengthwise between the connector end portions and which support the flexible circuitry thereon, the contact
15 spring members being movably mounted upon fulcrums such that upon insertion of the circuit card into the connector, an insertion edge of the circuit card impinges upon portions of the contact spring members which act as cam surfaces to thereby cause the contact spring members
20 to move about their associated fulcrums into engagement with the contacts of the circuit card.

Yet another object of the present invention is to provide an improved circuit card connector which applies reliable contact forces to a circuit card
25 inserted therein, the connector including a circuit card-engaging assembly having two opposing, spring members separated by an intervening space, the space defining an entrance portion of a card-receiving slot of the connector, the spring members having upwardly extending
30 spring arm portions and downwardly extending leg portions, the spring members engaging fulcrums which extend lengthwise along the connector and which support the spring members at locations between the spring arm and leg portions.

35 Still another object of the present invention is to provide an electrical connector having a spring-

biased circuit card-engaging assembly, wherein the card-engaging assembly includes a cradle spring having two fulcrums formed thereon, the fulcrums supporting a pair of contact springs on opposite sides of a circuit card-receiving slot of the connector, the contact springs having leg portions extending below the fulcrums and arm portions extending above the fulcrums, the contact springs being movable about their associated fulcrum points under urging of the circuit card when the circuit card is inserted into the connector, such that when the circuit card impinges upon the contact spring leg portions, the contact spring arm portions are urged to move into contact with opposing sides of the circuit card to thereby exert a card contact force normal to the circuit card contacts.

Yet still a further object of the present invention is to provide a high speed, high density electrical connector which has a relatively low circuit card insertion force and that includes a circuit card-engaging assembly which reliably engages the circuit card without the need for an external connector actuating mechanism, the circuit card-engaging assembly having a preload or biasing force applied thereto which biases the card-engaging into a operative position which readily receives the circuit card.

Summary of the Invention

5 In one principal aspect of the present invention and as exemplified by one embodiment of the invention, an improved circuit card connector is provided with a card-engaging assembly extending between two connector end portions and cooperates therewith to define a circuit card-receiving slot which extends lengthwise between the connector end portions. This card-engaging assembly includes a pair of opposing, spaced-apart spring members which support opposing lengths of flexible film circuitry. The spring members are supported between the connector end portions by a pair of fulcrums around which the spring members may move under the influence of the circuit card when the card is inserted into the card-receiving slot of the connector. The fulcrums in this embodiment may take the form of a pair of rails which extend lengthwise along the connector and support the spring members at locations intermediate opposing ends of the spring members.

20 In another principal aspect of the present invention and as exemplified by a second embodiment of the invention, the card-engaging assembly includes a pair of spring members supported on a pair of fulcrums which are formed as part of a cradle spring. The cradle has a plurality of upright engagement members that are received within a like plurality of openings disposed in the spring members which cooperate to maintain the spring members in place upon the cradle spring along the fulcrums.

30 In another principal aspect of the present invention, a preload, or biasing force, may be applied to the cradle spring and to the spring members to hold them in place within the connector and to maintain the spring members in an operative position in which the connector is ready to receive the circuit card. The insertion of the circuit card overcomes this preload and effects a

camming action with respect to the spring members to effect a contact between the flexible circuitry and the circuit card.

5 In still another principal aspect of the present invention and exemplified by still another embodiment of the invention, the contact springs of the card-engaging assembly are rotatably supported on the cradle spring at specific hinge points which serve as fulcrums about which the contact springs move under the
10 insertion of the circuit card.

In still yet another principal aspect of the present invention, the spring members include opposing arm and leg portions which contact the circuit card during insertion into the connector. The spring member
15 leg portions are disposed generally below the fulcrums while the spring member arm portion are disposed generally above the fulcrums, such that the fulcrums define points about which the spring member leg and arm portions move in opposite directions in response to the
20 insertion of the circuit card into the connector. During this insertion, the spring member leg portions move outwardly with respect to the card-receiving slot, while the spring member arm portions move inwardly toward the card-receiving slot such that the circuit card itself
25 acts as an actuator in applying a contact force between the flexible circuitry and the circuit card contacts.

In another further principal aspect of the present invention and as exemplified in another embodiment of the invention, a cradle spring is provided
30 to support a pair of contact springs. The cradle spring defines the lower extent of a circuit card-receiving slot of the connector and is supported on a connector base. The connector base includes means for applying an outward force to the cradle spring to ensure that the lower
35 extent of the card-receiving slot of the connector retains a predetermined width. The cradle spring

includes two engagement surfaces that extend lengthwise
on opposite sides of the card-receiving slot and which
serve as fulcrums while they support the contact springs
on opposite sides of the card-receiving slot. The
5 contact springs support flexible circuitry on opposing
sides of the card-receiving slot. The cradle spring
includes suitable engagement means which retain the
contact springs in place thereon. The connector also
includes a second biasing means which applies a force to
10 the contact springs to retain them in an open position
along the upper extent of the card-receiving slot.

These and other objects, features and
advantages of the present invention will be clearly
understood through a consideration of the following
15 detailed description.

Brief Description of the Drawings

In the course of the following description of the detailed description, reference will be made to the attached drawings wherein like reference numerals
5 identify like parts and wherein:

FIG. 1 is a perspective view of one embodiment of an improved circuit card connector constructed in accordance with the principles of the present invention;

10 FIG. 2 is an exploded perspective view of the connector of FIG. 1;

FIG. 3 is a cross-sectional view of the connector of FIG. 1 taken generally along lines 3-3 thereof illustrating a circuit card partially inserted into the card-receiving slot of the connector;

15 FIG. 4 is a view identical to FIG. 3, illustrating further insertion of the circuit card into the card-receiving slot of the connector to the extent where the circuit card contacts the spring member leg portions of the connector;

20 FIG. 5 is a view identical to FIG. 4 illustrating the circuit card fully inserted into the connector card-receiving slot;

FIG. 6 is a perspective view of one end of the connector of FIG. 1;

25 FIG. 7 is a perspective view of a second embodiment of an edge card connector constructed in construction with the principles of the present invention and illustrating a two-bay connector;

30 FIG. 8 is a perspective view of a circuit card-engagement assembly of a third embodiment of an edge card connector constructed in accordance with the principles of the present invention;

FIG. 9 is a view similar to FIG. 8, but with one half of the card-engagement assembly removed to illustrate the manner of engagement between the spring member and the fulcrum;

5 FIG. 10 is a perspective view of a card-engagement assembly utilized in a fourth embodiment of an edge card connector constructed in accordance with the principles of the present invention with one of the spring members removed for clarity;

10 FIG. 11 is a cross-sectional view of the card-engagement assembly of FIG. 10 showing the assembly in place within a connector housing at a rest position without a circuit card inserted therein and with the flat flexible circuitry removed for clarity;

15 FIG. 12 is a view identical to FIG. 11, but illustrating a circuit card fully inserted into the card-engagement assembly.

20 FIG. 13 is a perspective view of a card-engaging assembly utilized in a fifth embodiment of the present invention with one side thereof removed for clarity;

FIG. 14 is a cross-sectional view of a circuit card-engaging assembly of the type illustrated in FIG. 13 showing the initial insertion of a circuit card therein;

25 FIG. 15 is the same view as FIG. 14 but showing the circuit card fully inserted into the card-engagement assembly;

30 FIG. 16 is an exploded perspective view of a sixth embodiment of a circuit card connector constructed in accordance with the principles of the present invention;

FIG. 17 is a perspective view of the connector of FIG. 16 in place upon a printed circuit board;

FIG. 18 is a perspective view of the spring cradle component utilized in the card-engagement assembly of the connector of FIG. 16;

5 FIG. 19 is an end view of the spring cradle of FIG. 18 taken generally along lines 19-19 thereof;

FIG. 20 is a sectional view of the connector of FIG. 17 taken along lines 20-20 thereof;

10 FIG. 21 is a perspective view of one of the contact spring members utilized in the card-engagement assembly of the connector of FIG. 16; and

FIG. 22 is an enlarged view of one portion of the card-engagement assembly shown in FIG. 21 showing an alternate embodiment thereof.

Detailed Description of the Preferred Embodiments

FIG. 1 illustrates an edge card connector, generally indicated at 20, constructed in accordance with the principles of the present invention. The connector 20 is mounted to a primary printed circuit board 22 having a plurality of different circuits 24 disposed thereon leading to a plurality of associated contact pads or traces 26 located on a surface 28 of the circuit board 22.

The connector 20 is intended to provide a connection between the circuit board 22 and a secondary circuit card 30 having a generally planar substrate 32 and a plurality of contact pads 34 aligned along an insertion edge 36 of the circuit card 30. The circuit card 30 has its contact pads 34 disposed on both sides thereof, typically arranged in an array of one or more distinct rows, and these contact pads 34 may be electrically connected to each other in ways well known in the art to provide redundant contact surfaces in order to enhance the reliability of the circuit card-connector connection.

Turning now to FIG. 2, it can be seen that the connector 20 has a housing which generally includes two opposing end portions 40, preferably which are molded from an electrically insulative material, such as plastic. These end portions 40, serve to define the overall length of the connector 20, its housing and the circuit card-receiving slot 80 of the connector 20. In this regard, the end portions 40, each include a recess 42 formed therein which extends down from the upper surfaces 43 thereof through the body 44 of the end portions 40 to a predetermined depth D. These recesses 42 communicate with the interior, opposing faces 45 of the end portions 40 and may include, in proximity to the upper surface 43, ramped portions 46, that provide lead-

in surfaces into the recesses 42 to facilitate entry of the circuit card 30 into the connector card-receiving slot 80. Although the housing shown is defined by the two spaced-apart end portions 40 illustrated, it will be understood that the connector housing may include longitudinal sidewalls which extend the entire length of the connector 20 and which partially enclose the connector circuit card-engagement assembly 50.

The lower surfaces 47 of the end portions 40 are adapted to sit on the circuit board surface 28 and may be provided, as illustrated, with tapped openings 48 to accommodate mounting screws (not shown).

Alternatively, any other suitable mounting means known in the art may be utilized, such as mounting lugs or posts.

The end portion 40 may further include different openings 41, 49 for receiving various other components of the connector 20. The connector end portions 40 are preferably aligned lengthwise along a longitudinal axis of the connector 20 so that their respective recesses 42 and openings 41, 49 confront each other and preferably so that they are maintained in registration with respect to a centerline C (FIGS. 3-5) of the card-receiving slot 80 of the connector 20.

The connector end portions 40 not only define opposing ends of the connector circuit card-receiving slot 80 by way of their respective recesses 42, but they also support a circuit card-engagement assembly 50 therebetween. The components which make up this circuit card-engagement assembly 50 are individually illustrated in FIG. 2 and the operation of the assembly 50 is illustrated in FIGS. 3-5.

The card-engagement assembly 50 includes a pair of elongated rails 52 which extend lengthwise between the connector end portions 40 and which are supported thereby within respective openings 41 formed in the interior

faces 45 of the end portions 40. The rails 52 are supported between the upper and lower surfaces 43, 47 of the connector end portions 40 and on opposite sides of the centerline C of the recesses 42 and of the card-receiving slot 80. The rails 52 in turn support a pair of circuit card-engagement members illustrated as flexible spring member 53.

The spring members 53 are solid throughout their length as illustrated, which increases the compliance of the connector 100 in overcoming manufacturing irregularities that may occur in the circuit card 30 and which would ordinarily prevent effective contact between the contacts of the connector 20 and the contacts 34 of the circuit card 30 were the contacts to be a plurality of individual spring arms rather than the continuous spring members 53 illustrated.

As best shown in any of FIGS. 3-5, the spring members 53 of the first connector embodiment 20 may include a seat, or step, portion 54 located intermediate the ends of the spring members 53 for the purpose of defining surfaces of the respective spring members 53 which rest on the support rails 52 of the connector. As will be explained in greater detail below, the rails 52 serve as fulcrums F in order to provide points about which the spring members 53 move during insertion and removal of the circuit card 30 from the connector 20. The structure of the spring members 53 differs on opposite sides of the fulcrums F in that, in the embodiment illustrated, spring member leg portions 55 are provided which depend downwardly from the fulcrums F. The leg portions 55 include a lower bend therein to define an retention spring channel 56 at which a retention force is applied to the spring members 53.

The spring members 53 further include card engagement portions located on the opposite sides of the

5 seat portions 54, which are shown as spring arms 57 that
have a general C-shaped configuration. The spring arms
57 extend upwardly from the seat portions 54 of the
spring members 53 and may be considered as forming
10 distinct backbone portions 58 and circuit card contact
portions 60 which are bent back upon the backbone
portions 58 in the manner shown and which are
interconnected thereto by bight portions 59. The spring
member seat portions 54 are angularly disposed with
15 respect to the spring arm and leg portions 57, 55 and
intersect therewith such that the leg portions 55 are
offset both vertically and horizontally from the spring
member arm backbone portions 58 as illustrated. It
should be noted that the location of the spring member
20 seat portions 54 may be moved in order to change the
length of the lever arms provided by the spring member
arm and leg portions 57, 55 and thereby change the force
characteristics of the connector.

The spring members 53 may be formed from any
25 suitable material which imparts the desired degree of
resiliency to the card-engagement assembly 50. In this
regard the spring members 53 also provide support for a
plurality of contacts 62 of the connector 20 which are
formed in a length of flat flexible circuitry ("FFC") 64.
30 Two such lengths of flat flexible circuitry are
illustrated and this type of circuitry 64 is well known
in the art and variations may be used such as that
referred to as "flat flexible cable, flexible printed
circuitry and flexible film circuitry" as well as by
35 other descriptive names. However, for simplicity, this
description uses only the term "flat flexible circuitry,"
but it is understood that the use of this term is for
convenience only and is not to be understood as limiting
the scope of the invention. Although two lengths of
flexible circuitry 64 are illustrated in the Figures, it

will be understood that a single length of flexible circuitry 64 may be used as well for connectors of the present invention.

5 This flat flexible circuitry 64 typically has a laminated-style construction in which a plurality of flexible electrical contacts 62 (which may include strips of copper, gold or other conductive foils) bonded to a flexible, electrically insulative layer 65, such as a polyamide film. The flexible circuitry 64, in
10 appropriate applications, may also include several additional layers of contacts 62 separated by intervening insulating films in order to construct shielded flexible circuits. The flexible circuitry 64 may further include an outer insulative layer 71 which overlies portions of
15 the contacts 62.

The two strips of flexible circuitry 64 illustrated in FIGS. 2-5 are supported on the spring members 53 in a manner such that they substantially envelop the outer perimeter surfaces of the spring member arms 57, namely the spring member inner contact arm portions 60 and the spring member arm backbone portions 58. In this regard, the flexible circuitry 64 is bonded at one, upper end 66 thereof to the upper free end 68 of each spring member 53 and at an opposing end 67 to a
20 support plate 70 in any suitable manner.

The lower end 66 of the flexible circuitry 64 includes an open contact area 72 where the contacts 62 of the circuitry 64 are exposed for mounting to the appropriate surface 28 (FIG. 1) of the printed circuit board 22, while the other end 67 thereof has a similar contact area 73 where its outer protective and insulative layer 71 has been removed so that the contacts 62 thereon are exposed. These circuit card contact areas 73 are preferably positioned upon the spring arms 57 in the
30 location shown such that they overlie the contact arm
35

portions 60 that are disposed generally opposite the circuit card contact pads 34 when the circuit card 30 is fully inserted into the card-receiving slot 80. (FIG. 5.) As best shown in FIGS. 3-5, the lower ends 67 of the flexible circuitry 65 may be folded upon themselves as shown to form two opposing slots 74 (FIG. 5) which receive the support plate 70 therein. To increase the stability of the lower portion of the connector 20, the support plate 70 may be bonded in any suitable manner to the lower ends 67 of the flexible circuitry 64.

The flexible circuitry 64 and the spring members 53 which support it cooperate to define a circuit card-receiving slot 80 of the connector 20. This card-receiving slot 80 extends lengthwise along the connector 20 and communicates with the two recesses 42 formed in the opposing connector end portions 40. FIGS. 3-5 illustrate the interaction of the components of the card engagement assembly 50 during the insertion of a circuit card 30 into the connector 20.

With specific reference to FIG. 3, the connector 20 is shown in cross-section at an initial, or ready, position where the two opposing spring members 53 rest upon the fulcrum points F defined by the connector rails 52. In this position, the leg portions 55 (i.e., those portions of the spring members 53 which extend downwardly from the seat portions 54) contact each other in an abutting relationship lengthwise along the length of the rails 52 at the confronting surfaces 76 of the leg portions opposite the retention channels 56. In the embodiment shown, the opposing spring member leg portions 53 are maintained in this engagement by a series of retaining springs 78 which extend from the connector end portions 40 for a predetermined length on opposite sides of the centerline C of the card-receiving slot 80.

As shown in FIGS. 2 & 6, the retaining springs

78 are received supported in openings 49 formed in the
opposing interior faces 45 of the connector end portions
40. The retaining springs 78 each include a shaft
portion 82 which engages the connector end portions 40
5 and an inwardly extending spring arm 83 having a contact
portion 85 which is offset from the shaft portion 82 as
shown. The spring arms 83 extends inwardly of the
connector at an acute angle in order to provide a preload
to the retaining springs 78 and therefore serve to hold
10 the spring member leg portions 55 together in contact
generally adjacent the bottom of the card-receiving slot
80.

When the circuit card 30 is partially inserted
into the connector card-receiving slot 80 to the position
15 illustrated in FIG. 4, the insertion edge 36 of the
circuit card 30 impinges upon the spring member leg
portions 55. These spring member leg portions 55 act as
cams or levers in that further movement of the circuit
card 30 into the connector slot 80 will incrementally
20 separate the spring member leg portions 55 apart, causing
them to rotate about their fulcrums F, and resulting in
the spring member arms 57 rotating in opposite directions
also around the fulcrums F as shown by the arrows R in
FIG. 4. The downward insertion movement of the circuit
25 card 30 is partially resisted by the retention force
applied to the spring member leg portions 55 by the
retaining springs 78 in their contact against the
retention spring channels 56 in order that the card-
engagement assembly 50 is able to exert an internal
30 control of the card insertion.

Further movement of the circuit card 30 to a
completely inserted state as shown in FIG. 5 results in
the spring member leg portions 55 being spread apart a
distance equal to the width, or thickness, of the circuit
35 card 30, resulting in a secure mating being effected

between the circuit card contact pads 34 and the flexible contacts 62.

5 The movement of the spring member leg portions 55 in this manner forces the spring member arm portions 57 against opposing surfaces of the circuit card 30 and the contact portions 60 which are, in effect, cantilevered from the backbone and bight portions of the spring member arm portions 57, are thereby urged against the circuit card 30. The outward pressure applied to the 10 spring member leg portions 55 by insertion of the circuit card 30 results in an effective normal contact force N (FIG. 5) being applied by the spring member arm portions 57 against the circuit card 30. This normal force N firmly holds the flexible circuitry 62 and particularly, 15 its contact areas 73, against the circuit card contact pads 34. This concentrated normal force and the solid nature of the spring members 53 make the connector 20 more compliant and able to overcome manufacturing irregularities which may occur in the production of 20 circuit cards 30 wherein the opposing sides of the circuit card 30 are not entirely planar and level. Furthermore, during the insertion phase, the backbone portions 58 of the spring members 53 move from a position where they lie partially outside the sides of the 25 connector housing (FIG. 3) to a position where they lie within or aligned with the sidewalls 41 of the connector end portions.

The connector 20 of FIGS. 1-6 may be modified to accommodate more than one circuit card, or a longer 30 circuit card 104 as illustrated in FIG. 7, wherein another circuit card connector 100 constructed in accordance with the principles of the present invention may be seen to include two or more connector "bays" 102, 103, each of which is intended to receive either two 35 separate circuit cards or the circuit card 104 having two

distinct insertion edges 106, 107 separated by an
intervening notch 108. The structure of the connector
100 is generally the same as the first embodiment of the
connector 20 except that it includes an intermediate
5 housing portion 110 having two card-receiving recesses
112 formed on opposing sides 114, 115 thereof. The
opposing sides 114, 115 also include fulcrum support
openings and retaining spring openings to support the
fulcrum rails and retaining springs. Two card-engaging
10 assemblies 116, 117 are thereby supported between the
connector housing end and intermediate portions.

The first embodiment 100 described above
illustrates the general structural features of connectors
of the present invention. The card-engagement assembly
15 utilized in connectors of the present invention may take
forms other than the specific spring member-rail assembly
illustrated in FIGS. 1-6.

Turning now to FIGS. 8 & 9, such an alternate
20 card- engagement assembly 200 is shown as having two
opposing spring members 202 supported on a continuous
cradle spring 204. The cradle spring 204 has a generally
C-shape or U-shape as viewed from the end thereof and
includes a support base 206, two arms 208 which extend
25 upwardly from the base 206 and two fulcrums *F* which
extend along free ends 212 of the arms 208.

In this third embodiment, the fulcrums *F*
include a plurality of retention lugs 213 which are
spaced apart in a desired spacing lengthwise along the
fulcrums *F* between opposing ends of the card-engagement
30 assembly 200. These retention lugs 213, as shown best in
FIG. 9, are received within a series of openings 214
located along the seat portions 216 of the spring members
202. These openings 214 are larger than the retention
35 lugs 213 so as to minimize any contact which may inhibit
the ability of the spring members 202 to move upon their

respective fulcrums *F* due to interference between the two components.

5 FIGS. 10-12 illustrate a fourth embodiment of a
card-engagement assembly 300 which may be utilized in the
connectors of the present invention. In this embodiment,
the assembly 300 includes a continuous support cradle 302
having a generally U-shape or C-shape with two opposing
spring members 304 supported on two free edges 306 of the
cradle spring 302 that serve as fulcrums *F* for the spring
10 members 304. The spring members 304 each include a
plurality of slots 308 formed therein which receive
associated retention lugs 310 of the cradle spring 302
therein.

In this embodiment, both the slots 308 and the retention lugs 310 have a general T-shape that permits them to be easily assembled in an interlocking relationship and also ensures that the spring members 304 will be retained in their proper position upon the fulcrums F. The width of the top of the "tees" of the slots 308 is preferably greater than the width of the top of the "tees" of the retention lugs 310 and the bodies of the slots 308 are wider than the bodies of the retention lugs 310 in order to facilitate the assembly of the card-engagement assembly 300 without binding, once the assembly 300 is in its assembled position.

An important characteristic of all of the embodiments of the present invention disclosed herein is the ability of the spring members to "rock" or move back and forth upon their respective fulcrums in response to the insertion of a circuit card into the card-receiving slot of the connector and in effect, act as lever arms. This type of rocking action in the fourth embodiment is illustrated in FIGS. 11 & 12, wherein FIG. 11 illustrates the card-engagement assembly 300 in an initial, ready position in place within a connector housing 320, with the flexible circuitry removed for clarity and with one of the endwalls 322 of the housing being visible in the Figures. In this ready position, the spring members 304 rest in place upon the cradle spring 302 such that their opposing leg portions 324 contact each other within the perimeter of the circuit card-receiving slot 326. When a circuit card 330 is inserted into the slot 326, the circuit card insertion edge 328 engages the leg portions 324 of the spring members and causes them to spread apart, thereby rotating or rocking the spring members 304 about their fulcrums F. In this movement, the arm portions 332 of the spring members 304 are rotated in opposite directions about their respective fulcrums F and

thereby brought into contact against the opposing surfaces of the circuit card 330 as shown.

5 In one alternative embodiment, rather than relying upon a separate biasing means to position the spring member leg portions 324 together, the spring members may be constructed so that the leg portions 324 thereof have a length and mass less than that of the arm portions 332, so that the mass of the spring arm portions 332 applies a biasing force to the spring members causing them to pivot partially about the fulcrums F so that the spring member leg portions 324 will naturally extend into the card-receiving slot 326 and force the spring member arm portions 332 and the flexible circuitry supported thereon away from the insertion edge of the circuit card.

10 Hence, the spring member leg portions 324 which extend into the card-receiving slot 326 act as cam surfaces upon which the insertion edge and the opposing surfaces of the circuit card "ride" to thereby actuate of the connector to effect reliable engagement of the circuit card.

15 FIGS. 13-15 illustrate yet another embodiment of a card-engagement assembly 400 suitable for use in conjunction with connectors of the present invention in which the spring members 402 are supported upon a connector rocker base 404. The rocker base 404, as illustrated in FIG. 13, has a plurality of U-shaped supports 406 spaced apart lengthwise to define intervening spaces 408 therebetween. The spring members 402 have a series of slots 410 also spaced apart lengthwise along their leg portions 412 thereof. The spring member slots 410 receive the supports 406 of the rocker base 404, while the intervening spaces 408 of the connector rocker base 404 receive the leg portions 412 of the spring members 402. The spring members 402 and rocker base supports 406 are interconnected together by shafts 407 which extend lengthwise along common hinge

20

35

points F that serve as fulcrums for the spring members 402 to partially rotate about.

5 The spring members 402 are free to move, or rock about the hinge points F and accordingly the hinge points F are positioned at a location between the spring member arm and leg portions 413, 412 so that when the connector 400 is in a ready, non-engaged state, as shown in FIG. 14, where a circuit card 422 has not yet been inserted into the card-receiving slot 420, the spring members 402 will possess a tendency to rock "open" and the flexible circuitry contacts 431 will be maintained away from the insertion edge 424 of the circuit card 422. That is, the spring member arm portions 413 will tend to extend or rock outwardly at an angle to the card-receiving slot 420 of the connector, because of the location of the hinge points F and the difference in length and mass of the spring arm portions 413 as compared to that of the spring leg portions 412. This natural bias also causes the spring member leg portions 412 to move and extend inwardly of the card-receiving slot 420. Alternatively, means may be provided to bias the spring members 402 to this position.

15 Insertion of a circuit card 422 into the card-receiving slot 420 as shown in FIG. 15 causes the insertion edge 424 of the circuit card 422 to engage the cam surfaces 418 presented by the extent of the spring leg portions 412 into the card-receiving slot 420, causing the spring leg portions 412 to rotate outwardly in the manner shown, which brings the spring member arm portions 413 inwardly and the flexible circuitry 430 supported thereon into contact with the contacts 432 on opposing surfaces of the circuit card 422.

20 It therefore can be seen that the present invention provides a cam-like contact mechanism as its card-engagement assembly with a small number of

components in which the cam-like contact mechanism utilizes simple spring concepts.

FIGS. 16-21 illustrate still another embodiment of a circuit card connector 500 constructed in accordance with the principles of the present invention. In this embodiment, the connector card-engagement assembly 502 includes means for applying preloads or biasing forces to certain components of the assembly 502. The connector 500 includes two opposing end portions 504, each of which has a vertical recess 506 disposed therein which receive the opposing ends of a circuit card (not shown) inserted into the connector 500. These recesses 506 serve to form the ends of the circuit card-receiving slot 508 of the connector 500 and accordingly, are aligned with each other along a longitudinal axis of the connector 500. The connector end portions 504, similar to the embodiment of FIGS. 1-6, may include ramped surfaces 510 which serve as lead-ins to the card-receiving slot 508 and have flat lower mounting surfaces 512 which are suitable for mounting the connector 500 upon a surface of a printed circuit board 513 in any suitable manner.

The connector end portions 504 may also include hollow cavities or recesses 514 formed in the lower surfaces 512 which receive opposing end tabs 516 of a connector base member 518. The base member 518 extends lengthwise between the connector end portions 504 and has a width slightly greater than the end portions 504 in order to provide support for the flexible circuitry 560 of the connector 500. The base member 518 further has a flat central portion 520 (FIG. 20) which may be considered as defining the lowermost extent 522 of the card-receiving slot 508. A plurality of posts 524 extend upwardly from the base member 518. These posts 524 are spaced apart from each other both lengthwise and laterally within the connector 500 and further flank the

base member central portions 520 to provide a preload, or biasing force to the card-engagement assembly cradle spring 530 as explained in greater detail below.

5 Additionally, the posts 524 of the connector base member 518 will hold the cradle spring 530 in position to maintain a predetermined separation between the free ends of the cradle spring regardless of the tolerances to which the cradle spring may be made.

10 The cradle spring 530 extends lengthwise between the connector end portions 504 and includes a plurality of transverse slots 532 which are spaced apart from each other in the longitudinal direction as seen best in FIG. 18 and which are dimensioned to receive the posts 524 of the base member 518. As seen in FIG. 19,
15 the cradle spring 530 has a base portion 534 and two sidewalls 535 extending upwardly therefrom which terminate in free ends 536. The free ends 536 define surfaces which act as two fulcrums *F* for the card-engaging assembly 502. These fulcrums *F* lie on opposite
20 sides of the centerline *C* of the connector 500 and of the card-receiving slot 508 and support a pair of contact springs 550. The free ends 536 preferably further include a series of engagement lugs or bent portions 538 which serve to retain the contact springs 550 in place
25 along the fulcrums *F*. These lugs 538 extend laterally inwardly from the sidewalls 535 so that the undersurfaces 540 thereof will engage the contact springs 550.

The posts 524 of the base member 518 have non-planar exterior surfaces 542 which are somewhat
30 complimentary to the configuration of the cradle spring sidewalls 535 and may also be slightly laterally displaced outwardly with respect to the sidewalls 535 in order to apply a predetermined or outwardly directed biasing force against the cradle spring 530. In other
35 words, the distance between the exterior surfaces of a

pair of laterally aligned posts 524 is slightly greater than the horizontal width of the cradle spring slots 632.

5 A pair of contact springs 550 extend lengthwise along the cradle spring 530 and include, as best
10 illustrated in FIGS. 16 & 21, a plurality of openings 552 that extend lengthwise along seat portions 554 of the contact springs 550 and which are spaced apart in a similar spacing as the cradle spring engagement lugs 538. When assembled, the contact springs 550 rest on the
15 fulcrums F of the cradle spring free ends 536 and the engagement lugs 538 extend through the openings 552. The contact springs 550 may be considered as having in end profile, a general S-type shape (the leftmost contact spring 550 in FIG. 20 having such an S-type shape and the
20 leftmost contact spring 550 being a mirror image thereof) with distinct contact spring arms 555 and contact spring legs 556 located on opposite sides of the seat portions 554 thereof and extending lengthwise along the connector 500 at different levels within the card-receiving slot 508.

The contact spring arms 555 are located in the upper extent of the card-receiving slot 508, while the contact spring legs 556 are located in the lower extent thereof. The contact springs 550 are free to move or
25 "rock" about the fulcrums F of the cradle spring 540 as described earlier herein with respect to the previous embodiments under the urging of a circuit card. The contact springs 550 serve as support surfaces for flat flexible circuitry 560 which is applied to the outer
30 surfaces 558 of the contact spring arms 555, and as previously noted, may include a plurality of electrically conductive contacts 562 disposed thereon (FIG. 17.) The contacts 562 may be protected by an exterior insulative layer 564 which extends along the top and sides of the
35 connector 500, but which is not applied over the contacts

562 at two contact areas 565, 566 located respectively within the connector slot 508 as shown in FIG. 20 and at the bottom side edges of the connector along feet 519 of the base member 518 where the contacts of the lower
5 contact areas 566 are aligned and soldered to contact pads 569 of the circuit board 513.

The connector 500 includes another means for preloading the card-engagement assembly 502 shown illustrated in FIG. 16 as a pair of clips 570 which are
10 received within outer slots 572 of the connector end portions 504. These clips 570 are generally C-shaped and include a connector housing engagement section 573 which engages the connector housing slots 572 and a pair of preloading spring arms 574 extending longitudinally
15 therefrom. These preloading spring arms 574 are separated by a preselected spacing S and they extend lengthwise within the connector 500 along the contact spring arms 555 as shown in FIG. 20. The connector preloading spring arms 574 may include engagement heads
20 575 disposed at the free ends 576 thereof which have a barb-like configuration which is adapted to engage the contact spring 550 by pressing outwardly against the inner surfaces 558 of the spring arm portions 555 thereof as indicated in FIG. 20.

25 This outwardly biasing force will, in effect, preload the contact springs 550 so that they will have a tendency to move in opposite directions about their associated fulcrums F to thereby draw the spring leg portions 556 into the card-receiving slot 508. As
30 illustrated with the previous embodiments described herein, the spring leg portions 556 have projecting cam surfaces 559 which the insertion edge of the circuit card will impinge upon when inserted into the card-receiving slot 508, thereby moving the contact spring arm and leg
35 portions 555, 556 in opposite directions about the

fulcrums to bring the exposed contact areas 562 of the flexible circuitry into contact with the contact pads of the circuit card.

5 FIG. 22 illustrates another embodiment of a
card-engagement assembly 600 in which the contact spring
602 is supported upon an assembly cradle 604 similar to
the embodiment previously described. However, in this
embodiment 600, the spring leg portions 606 of the
10 contact springs 602, may, in the areas beneath the
fulcrums F, be insulated to prevent any conductivity from
occurring between the spring leg portions 606 and the
circuit board 608. This may be accomplished by applying
an insulator or insulating layer 610 to the contact
15 spring leg portions 606 as illustrated. The insulating
layer 610 may include a material with inherent lubricity
which would serve to reduce circuit card insertion
forces.

5 Connectors of the present invention may be
constructed from a variety of materials. In this regard,
the contact springs and the cradle spring may be formed
from alloys such as beryllium copper, phosphor bronze and
10 stainless steel which possess desirable spring
characteristics. The connector end portions and base may
be machined, cast or molded from materials such as
aluminum, zinc, liquid crystal polymer. These are but
examples of suitable materials and it will be understood
15 that other suitable materials may also be used for the
various connector components.

 Accordingly, it will be appreciated that the
embodiments of the present invention which have been
discussed herein are merely illustrative of a few
15 applications of the principles of the invention.
Numerous modifications may be made by those skilled in
the art without departing from the true spirit and scope
of the invention.

1. An electrical connector for providing an electrical interconnection between a plurality of contacts on a primary circuit board and a plurality of contacts on a printed circuit card, the circuit card having an edge which is insertable into and removable from a card-receiving slot, said circuit card being generally planar and having first and second circuit faces, each of said first and second circuit faces having a plurality of circuit card contacts disposed thereon, said connector being characterized by:

a circuit card engagement assembly including a pair of fulcrums located on opposite sides of a longitudinal center line of said slot, a pair of contact members extending lengthwise along said connector on opposite sides of said center line such that one of said contact members is associated with one of said fulcrums and the other of said contact members is associated with the other of said fulcrums, each of said contact members being movably supported on its associated fulcrum for movement between first and second positions and each of said contact members having upper and lower portions;

flat, flexible circuitry extending lengthwise along said connector and supported on said contact members on opposite sides of said center line, said circuitry having a first plurality of contacts for electrically interconnecting to said plurality of contacts on said primary circuit board and a second plurality of contacts for electrically interconnecting to said plurality of contacts on said printed circuit card;

said upper portions of said contact members carrying said second plurality of contacts, and

said lower portions of said contact members being biased toward the center line of the slot for engagement with the circuit card as the circuit card is inserted into the slot, the lower portions adapted to be moved about their respective fulcrums away from the

center line of the slot in response to the insertion of the circuit card and the upper portions being moved about their respective fulcrums toward the circuit card as the circuit card is inserted, said second plurality of
5 contacts making contact with the electrical contacts of the circuit card when the circuit card is fully inserted into the slot.

2. An electrical connector in accordance with
10 claim 1 wherein said connector further comprises two opposing housing end portions, said connector housing end portions including respective lower support surfaces for positioning said connector housing end portions adjacent
15 said primary circuit board, said connector housing end portions further including respective upper surfaces spaced apart from said lower support surfaces, each of said connector housing end portions further including a circuit card-receiving recess disposed in said upper
20 surfaces thereof and extending within said connector housing end portions to a predetermined depth, said circuit card-receiving recesses being generally aligned in an opposing relationship along a longitudinal axis of said connector.

3. An electrical connector in accordance with
25 claim 2 further comprising a connector base extending lengthwise between said connector housing end portions in proximity to the level of said lower surfaces of said connector housing end portions.

4. An electrical connector in accordance with
30 claim 3 wherein said fulcrums generally extend the length of the contact members and said connector base includes means for supporting said fulcrums in their lengthwise
35 extent between said connector housing end portions.

5. An electrical connector in accordance with claim 1 further comprising a cradle spring extending lengthwise between said connector housing end portions, the cradle spring having two spaced apart free ends, defining said fulcrums.

6. An electrical connector in accordance with claim 5 further comprising a connector base extending between connector housing end portions and wherein said cradle spring has a general C-shape, said connector base having means for supporting said cradle spring in its lengthwise extent in said connector.

7. An electrical connector in accordance with claim 6 further comprising means for applying a preload to said cradle spring to maintain said cradle spring free ends spaced apart from each other.

8. An electrical connector in accordance with claim 7 wherein said cradle spring includes a plurality of transverse slots, and wherein said cradle spring preloading means includes a plurality of posts extending from said connector base into said cradle spring slots and against said cradle spring.

9. An electrical connector in accordance with claim 5 wherein said cradle spring comprises a plurality of engagement members disposed lengthwise and said contact members include a plurality of openings which receive said cradle spring engagement members therein, said cradle spring engagement members retaining said contact members in place upon said fulcrums.

10. An electrical connector in accordance with claim 9 wherein said engagement members are generally T-shaped and said openings in said contact members include generally T-shaped slots, said T-shaped slots being slightly larger than said T-shaped engagement members.

11. An electrical connector in accordance with claim 9 wherein said engagement members extend inwardly from said cradle spring free ends toward said circuit card-receiving slot.

12. An electrical connector in accordance with claim 1 wherein said contact members comprise seat portions for engaging the associated fulcrums, said contact members further comprising distinct leg and arm portions which extend away from the seat portions on opposite sides of the seat portion.

13. An electrical connector in accordance with claim 12 wherein, in a first operative position said circuit card-receiving slot has no circuit card inserted therein and said leg portions of said contact members extend into said circuit card-receiving slot, and in a second operative position, a circuit card is inserted in said circuit card-receiving slot, said leg portions of said contact members are contacted by said circuit card, and are thereby moved apart from each other, thereby moving said arm portions of said contact members and said flexible circuitry supported thereon about said fulcrums toward said circuit card-receiving slot and into engagement with said circuit card contacts.

14. An electrical connector in accordance with claim 13 wherein when said contact members are in said first operative position, said contact member leg portions are spaced apart a distance less than the
5 thickness of said circuit card to be inserted into said circuit card-receiving slot, and further comprising means for biasing said contact members when said connector is in said first operative position.

10 15. An electrical connector in accordance with claim 14 wherein said contact member biasing means comprises a pair of spring retainers supported in connector housing end portions, said spring retainers
15 extending into engagement with said contact member leg portions to bias them inwardly into said circuit card-receiving slot when said contact members are in said first operative position.
