

Description

The present invention relates to a submersible pump, and particularly to a submersible pump which has a particularly simple structure and may be readily assembled.

From FR-A-2 563 060, a submersible pump is known which comprises: a discharge casing open at the bottom thereof; a motor case fixed inside the discharge casing and containing therein a motor for driving an impeller; a support plate positioned so as to close an opening of said discharge casing for supporting said motor case; a downwardly concaved pump casing placed under the support plate for defining a volute chamber between it and the support plate; and a downwardly concaved strainer placed under the pump casing for defining a suction chamber between it and the pump casing, said discharge casing having a stepped flange of increased diameter which is integrally formed along the periphery of the opening of said discharge casing, wherein within a stepped portion of said stepped flange there are sequentially mounted respective peripheral portions of said support plate, of said pump casing, and of said strainer.

Generally, conventional submersible pumps of this type are assembled by laying the discharge casing, motor case support plate, pump casing and strainer on one another, and securing them together at their superposed portions by means of bolts.

However, conventional pumps, which are assembled by bolting the superposed portions of the individual members, present problems in that they are not easy to assemble or handle.

Namely, in assembling such conventional pumps, at least the respective superposed portions between the discharge casing and the motor case, between the motor case and the support plate, between the discharge casing and the support plate, and between the support plate and the strainer must be secured by means of bolts. In this case, the pump casing is bolted together with the discharge casing and the support plate or with the support plate and the strainer. Therefore, many superposed portions must be secured by means of different kinds of bolts. Also, since many bolt holes must be aligned together in assemblage, not only is alignment of these bolt holes required, but also these bolt holes must be machined to a high degree of accuracy.

An object of the present invention is, therefore, to overcome the above-mentioned problems associated with the prior art by providing a submersible pump which has of a particularly simple structure and may be readily assembled.

In order to achieve the above-mentioned object, a submersible pump according to one aspect of the present invention comprises: a discharge casing open at the bottom thereof; a motor case fixed inside the discharge casing and containing therein a motor for

driving an impeller; a support plate positioned so as to close an opening of said discharge casing for supporting said motor case; a downwardly concaved pump casing placed under the support plate for defining a volute chamber between it and the support plate; and a downwardly concaved strainer placed under the pump casing for defining a suction chamber between it and the pump casing. In this submersible pump, said discharge casing has a stepped flange of increased-diameter which is integrally formed along the periphery of the lower end opening thereof. Within a stepped portion of the stepped flange, there are sequentially mounted respective peripheral portions of said support plate, of said pump casing, and of said strainer. Said discharge casing and said support plate are fastened together by first bolts vertically extending therethrough. Then, said support plate, said pump casing and said strainer are fastened together by second bolts vertically extending therethrough.

In accordance with another aspect of the present invention, a submersible pump which comprises: a discharge casing open at the bottom thereof; a motor case fixed inside the discharge casing and containing therein a motor for driving an impeller; a support plate positioned so as to close an opening of said discharge casing for supporting said motor case; a downwardly concaved pump casing placed under the support plate for defining a volute chamber between it and the support plate; and a downwardly concaved strainer placed under the pump casing for defining a suction chamber between it and the pump casing. In this submersible pump, said motor case has an outwardly extending connection flange formed integral therewith along the lowermost peripheral portion thereof. The connection flange and said support plate are fastened together by third bolts vertically extending therethrough. Said discharge casing has a stepped flange of an increased-diameter which is integrally formed along the periphery of a lower end opening thereof. A partition plate is secured to a stepped portion of the stepped flange. Under the partition plate secured to the stepped portion, there are sequentially mounted respective peripheral portions of said support plate, of said pump casing and of said strainer. Said partition plate, said support plate, said pump casing and said strainer are fastened together by fourth bolts vertically extending therethrough.

The pump according to the first aspect of the present invention may be simply assembled by sequentially mounting the respective peripheries of the support plate, pump casing and strainer within the stepped portion of the stepped flange formed along the periphery of the discharge casing opening, subsequently fastening the first bolts to secure the discharge casing and support plate together, followed by fastening the second bolts to secure the support plate, pump casing and strainer together. In this way, the alignment of the respective elements to be as-

sembled is easily effected; the overall pump can thus be easily assembled by fastening the first and second bolts.

In accordance with the second aspect of the present invention, the third bolts are fastened to firstly assemble the motor case and the support plate for supporting the motor case, then securing the partition plate to the stepped portion of the stepped flange formed along the periphery of the discharge casing opening, sequentially placing the respective peripheries of the support plate, pump casing and strainer under the partition plate within the stepped portion, and finally, fastening the fourth bolts to assemble the partition plate, support plate, pump casing and strainer together. It is thus possible to reduce the length of the third bolts, and the shorter third bolts make the assembling process easier so that the entire pump can be assembled more easily.

The above and other objects, features and advantages of the present invention will become more apparent from the following description when taken in conjunction with the accompanying drawings in which a preferred embodiment of the present invention is shown by way of illustrative examples.

Fig. 1 is a side elevational view of an embodiment of the submersible pump according to the present invention;

Fig. 2 is a longitudinal sectional view of the same;

Fig. 3 is a plan view of the same;

Fig. 4a is a sectional view showing a supporting structure for a power supply cord of the first embodiment;

Fig. 4b is a fragmentary sectional view taken along line IV - IV in Fig. 2;

Fig. 5 is a fragmentary longitudinal sectional view of a second embodiment according to the present invention;

Fig. 6 is a plan view showing a pump casing of the second embodiment;

Fig. 7 is a sectional view taken along line VII - VII shown in Fig. 6;

Fig. 8 is a sectional view taken along line VIII - VIII shown in Fig. 6; and

Fig. 9 is a sectional view taken along line IX - IX shown in Fig. 6.

Embodiments of the submersible pump according to the present invention will now be described with reference to the accompanying drawings.

In Fig. 1, reference numeral 1 designates a discharge casing which is formed by pressing and which is open at the bottom. Inside the discharge casing 1, a motor case 2 is fixed, as shown in Fig. 2, a stator 3a of a motor 3 being fixed to the inner surface of the motor case 2. The motor 3 has a rotor 3b which has an upright shaft 5 fixed thereto. The upright shaft 5 is rotatably supported by bearings 6 and 7 mounted on the top and bottom of the shaft 5.

The upper bearing 6 is supported inside a recess

formed in a top plate 2a of the motor case 2. A case including drying agent 8 for removing moisture is interposed between the recessed portion of the top plate 2a and a top plate 1a of the discharge casing 1. The lower bearing 7 is supported inside a recess formed in a top plate 9a of a bearing supporting plate 9. This bearing supporting plate 9 is sandwiched between the lower end of said motor case 2 and a support plate 10 which supports the motor case 2. Reference numeral 11 designates an O-ring sealing between the motor case 2 and the bearing support plate 9, and 12 and 13 designate oil seals. The upper oil seal 12 is supported in the recess formed in the bearing supporting plate 9, while the lower oil seal 13 is supported in a recess formed in the support plate 10. Oil 14 charged between the bearing supporting plate 9 and the support plate 10 is sealed by these oil seals 12 and 13.

The upright shaft 5 extends downwardly through and beyond the support plate 10, an impeller 15 being secured to the lower end of the upright shaft 5. The impeller 15 is surrounded by a downwardly concaved pump casing 17 which defines a volute-shaped pressure chamber 16 between it and the support plate 10. The pump casing 17 has a bottom plate which is provided with a suction port 18 opening at the center thereof. A downwardly concaved strainer 20 defining a suction chamber 19 therein is provided outside the pump casing 17. The strainer 20 has a plurality of circumferentially equally spaced apart and vertically extending slits 21, 21, ... formed in the wall thereof.

The discharge casing 1 has an increased-diameter stepped flange 23 formed integral therewith along the circumference of the lower end opening thereof. Within a stepped portion 23a of the stepped flange 23, the peripheral portions of the above-mentioned support plate 10, the pump casing 17 and the strainer 20 are sequentially mounted. The support plate 10, the pump casing 17 and the strainer 20 are fastened together by means of a plurality of second bolts 25, 25, ..., 25 vertically extending therethrough, while the discharge casing 1 and the support plate 10 are fastened together by means of a plurality of first bolts 26, 26, ..., 26 vertically extending therethrough.

In accordance with this embodiment, the first bolts 26 are firstly fastened and the second bolts 25 are subsequently fastened to assemble the support plate 10, the pump casing 17 and the strainer 20 together. Thus, the entire pump can be easily assembled. Further, when the flange 23 has radially inwardly extending projections 23b formed on the inner surface thereof and the support plate 10, the pump casing 17 and the strainer 20 have corresponding grooves 24 formed in their respective peripheral portions for receiving the projections 23b therein, the entire pump may be further easily assembled by engaging the projections 23b and the corresponding receiving grooves 24 together to easily position the members

1, 10, 17 and 20 (see Fig. 4b).

The top plate 1a of the discharge casing 1 has a discharge mouth 29 to which a discharge pipe 30 is connected, as shown in Figs. 2 and 3. A handle 31 is connected between the discharge pipe 30 and the above-mentioned top plate 1a. The handle 31 has a structure in which a steel base member 32 is sandwiched between top and bottom plastics covers 33a and 33b, respectively, which are fastened together by screws 35.

The top cover 33a has a cord supporting suction 36 provided at an end thereof, which cord supporting section 36 has a catch groove 36a formed therein, as clearly shown in Fig. 3. A flexible cord 37 is held fast in the catch groove 36a. This cord 37 has one end connected to the above-mentioned motor 3 and has the opposite end connected to a float switch 38. This float switch 38 comprises a mercury switch which is turned on to allow the motor 3 to be energized when the float switch 38 has been raised to a predetermined level, as shown by imaginary lines in Fig. 1, and is turned off when the float switch 38 lowers to a predetermined level, as shown by solid lines in the same figure. In Fig. 2, 1b is a terminal screw for connecting to an earth cable (not shown).

The operation of this pump is as follows: When the pump is placed under water, the above-mentioned float switch 38 connected to one end of the flexible cord 37 will be buoyed up to the level shown by the imaginary lines in Fig. 1, whereby the switch is turned on to allow the motor 3 to be energized. The impeller 15 will then be driven for rotation, thereby causing water to be drawn into the suction chamber 19 through the slits 21 in the strainer 20. After being drawn into the impeller 15 through the suction port 18 of the pump casing 17, a centrifugal force is imparted by the impeller 15 and the water is discharged into the volute-shaped pressure chamber 16 under a swirling motion. The swirling water thrown into the volute-shaped pressure chamber 16 will flow, through a circular opening 10a formed in the support plate 10, into an annular flow path 48 between the discharge casing 1 and the motor case 2, where the water swirls thus cooling the periphery of the motor 3 and is then discharged to the outside through a discharge mouth 29, which is formed in the discharge casing 1, and through the discharge pipe 30. As the water surface is lowered by the pumping, the float switch 38 will lower to the position shown by solid lines in Fig. 1, where it is turned off to de-energize the motor 3 thereby stopping the pumping.

Just under the above-mentioned opening 10a, a discharge guide plate 49 is fixed in a manner in which it extends between the support plate 10 and the pump casing 17. This discharge guide plate 49 is curved and has a lower end curved toward the viewer's side in Fig. 2 and fixed to the upper surface of the bottom of the pump casing 17. The discharge guide plate 49

serves to guide the swirling water from the pressure chamber 16 to the opening 10a, whereby the swirling water can easily flow into the opening 10a.

A power supply cord 39 for the motor 3 extends out of the discharge casing 1 through the top plate 1a of the discharge casing 1 (see Fig. 4a). A holder 40, which is formed by molding hard rubber, is fitted in this top plate 1a. A plastic receptacle member 41 is provided on the underside of this holder 40. The top plate 1a and the receptacle member 41 are fastened together by means of screws 43 with the holder interposed between the top plate 1a and the receptacle member 41. The holder 40 has a through hole 40a formed therethrough for insertion therethrough of the power supply cord 39. An inwardly projecting projection 45 is formed on a midway portion of the through hole 40a. In this arrangement, the upper surface of the lower portion of the holder 40 and the lower surface of top plate 1a may be kept in close contact with each other and the projection 45 on the holder 40 presses the periphery of the power supply cord 39, whereby it is ensured that water from outside will not penetrate into the discharge casing 1 or further into the motor case 2, so that electric leakage can surely be avoided.

Fig. 5 shows another embodiment of the invention.

In this embodiment, a motor case 2 has an outwardly bent connection flange 51 formed integral therewith along the lowermost peripheral edge portion thereof. A support plate 10 is secured to the connection flange 51 by means of a plurality of third bolts 53. A ring-shaped partition plate 55 is beforehand secured to a stepped portion 23a of a stepped flange 23 on a discharge casing 1 by spot weldings 56. The above-mentioned support plate 10 secured to the motor case 2, a pump casing 17 and a strainer 20 are secured to the partition plate 55 by means of a plurality of fourth bolts 57.

The pump casing 17 has a volute-shaped pressure chamber 16 as shown in Fig. 6. The pressure chamber 16 is defined by a casing shell 17a of the pump casing 17, as clearly shown in Figs. 7 and 8. At the end of the pressure chamber 16, the bottom of the casing shell 17a is bent upwardly to form a curved bottom 17b which forms a discharge guide surface 17c for guiding swirling water. In this embodiment, the swirling water in the pressure chamber 16 is guided along the discharge guide plate 17c to an opening 10a of the support plate 10. Reference numeral 58 designates a drain plug. The arrangement of this embodiment is otherwise substantially identical to the first embodiment shown in Fig. 2.

The process of assembling this submersible pump is as follows: Firstly, a bearing supporting plate 9 is mounted on the underside of the motor case 2 with an O-ring 59 interposed between them, and then the support plate 10 is placed thereon. The support

plate 10 and the connection flange 51 are then screwed together by means of third bolts 53. Subsequently, the peripheries of the above-mentioned support plate 10, the pump casing 17 and the strainer 20 are sequentially mounted in the stepped portion 23a of the stepped flange 23.

Since the partition plate 55 is secured to the stepped portion 23a, the above-mentioned support plate 10, the pump casing 17 and the strainer 20 are screwed to the partition plate 55 by means of fourth bolts 57. In accordance with this arrangement, the pump may be easily assembled by fastening the third bolts 53 and the fourth bolts 57.

Since, in this embodiment, the third bolts 53 are greatly reduced in length as compared to the first bolts 26 used in the first embodiment, the pump can be assembled still more easily.

If bolts are long and the length from the bolt insertion section of an upper portion of the discharge casing 1 to the threaded holes in the support plate 10 is also long, as shown in Fig. 2, then assembling the pump becomes slightly difficult. In this embodiment, however, such a difficulty caused by excessive bolt length is completely overcome since the third bolts 53 are extremely short.

Further, since the motor case 2 and the support plate 10 are secured together by means of the third bolts 53, it is possible to assemble the motor 3 and test the operation of such motor before the assembling of the entire pump.

From the foregoing, it is clear that, in accordance with the present invention, a submersible pump has a simple structure and the entire pump can be assembled easily.

Claims

1. A submersible pump comprising: a discharge casing (1) open at the bottom thereof; a motor case (2) fixed inside the discharge casing (1) and containing therein a motor (3) for driving an impeller (15); a support plate (10) positioned so as to close an opening of said discharge casing (1) for supporting said motor case (2); a downwardly concaved pump casing (17) placed under the support plate (10) for defining a pressure chamber (16) between it and the support plate (10); and a downwardly concaved strainer (20) placed under the pump casing (17) for defining a suction chamber (19) between it and the pump casing (17), said discharge casing (1) having a stepped flange (23) of increased-diameter which is integrally formed along the periphery of the opening of said discharge casing (1), wherein within a stepped portion of said stepped flange there are sequentially mounted respective peripheral portions of said support plate, of said pump casing,

and of said strainer, said submersible pump being characterized in that said discharge casing (1) and said support plate (10) are fastened together by first bolts (26) vertically extending therethrough, and in that said support plate (10), said pump casing (17) and said strainer (20) are fastened together by second bolts (25) vertically extending therethrough.

2. A submersible pump as claimed in Claim 1, wherein an annular flow path (48) is defined between said discharge casing (1) and said motor case (2) and said first bolts (26) extend vertically through said annular flow path (48).

3. A submersible pump as claimed in Claim 1 or 2, wherein an annular space is defined between said pump casing (17) and said strainer (20) and said second bolts (25) extend vertically through said annular space.

4. A submersible pump as claimed in Claim 1 or 2, wherein a radially inwardly extending projection (23b) is formed on the inner surface of said stepped flange (23), and a groove (24) for receiving said projection (23b) therein is formed on the peripheral portion of each of said support plate (10), said pump casing (17) and said strainer (20).

5. A submersible pump as claimed in Claim 2, wherein said support plate (10) includes an opening (10a) communicated with said annular flow path (48), a curved discharge guide plate (49) is fixed between said support plate (10) and said pump casing (17) so as to guide a water from said pressure chamber (16) to said annular flow path (48) through said opening (10a) in said support plate (10).

6. A submersible pump comprising: a discharge casing (1) open at the bottom thereof; a motor case (2) fixed inside the discharge casing (1) and containing therein a motor (3) for driving an impeller (15); a support plate (10) positioned so as to close an opening of said discharge casing (1) for supporting said motor case (2); a downwardly concaved pump casing (17) placed under the support plate (10) for defining a pressure chamber (16) between it and the support plate (10); and a downwardly concaved strainer (20) placed under the pump casing (17) for defining a suction chamber (19) between it and the pump casing (17), said discharge casing (1) having a stepped flange (23) of an increased-diameter which is integrally formed along the periphery of an opening thereof, wherein under a partition plate (55) secured to a stepped portion (23a) of the stepped flange (23) there are sequentially mounted re-

plate 10 and the connection flange 51 are then screwed together by means of third bolts 53. Subsequently, the peripheries of the above-mentioned support plate 10, the pump casing 17 and the strainer 20 are sequentially mounted in the stepped portion 23a of the stepped flange 23.

Since the partition plate 55 is secured to the stepped portion 23a, the above-mentioned support plate 10, the pump casing 17 and the strainer 20 are screwed to the partition plate 55 by means of fourth bolts 57. In accordance with this arrangement, the pump may be easily assembled by fastening the third bolts 53 and the fourth bolts 57.

Since, in this embodiment, the third bolts 53 are greatly reduced in length as compared to the first bolts 26 used in the first embodiment, the pump can be assembled still more easily.

If bolts are long and the length from the bolt insertion section of an upper portion of the discharge casing 1 to the threaded holes in the support plate 10 is also long, as shown in Fig. 2, then assembling the pump becomes slightly difficult. In this embodiment, however, such a difficulty caused by excessive bolt length is completely overcome since the third bolts 53 are extremely short.

Further, since the motor case 2 and the support plate 10 are secured together by means of the third bolts 53, it is possible to assemble the motor 3 and test the operation of such motor before the assembling of the entire pump.

From the foregoing, it is clear that, in accordance with the present invention, a submersible pump has a simple structure and the entire pump can be assembled easily.

Claims

1. A submersible pump comprising: a discharge casing (1) open at the bottom thereof; a motor case (2) fixed inside the discharge casing (1) and containing therein a motor (3) for driving an impeller (15); a support plate (10) positioned so as to close an opening of said discharge casing (1) for supporting said motor case (2); a downwardly concaved pump casing (17) placed under the support plate (10) for defining a pressure chamber (16) between it and the support plate (10); and a downwardly concaved strainer (20) placed under the pump casing (17) for defining a suction chamber (19) between it and the pump casing (17), said discharge casing (1) having a stepped flange (23) of increased-diameter which is integrally formed along the periphery of the opening of said discharge casing (1), wherein within a stepped portion of said stepped flange there are sequentially mounted respective peripheral portions of said support plate, of said pump casing,

and of said strainer, said submersible pump being characterized in that said discharge casing (1) and said support plate (10) are fastened together by first bolts (26) vertically extending therethrough, and in that said support plate (10), said pump casing (17) and said strainer (20) are fastened together by second bolts (25) vertically extending therethrough.

2. A submersible pump as claimed in Claim 1, wherein an annular flow path (48) is defined between said discharge casing (1) and said motor case (2) and said first bolts (26) extend vertically through said annular flow path (48).
3. A submersible pump as claimed in Claim 1 or 2, wherein an annular space is defined between said pump casing (17) and said strainer (20) and said second bolts (25) extend vertically through said annular space.
4. A submersible pump as claimed in Claim 1 or 2, wherein a radially inwardly extending projection (23b) is formed on the inner surface of said stepped flange (23), and a groove (24) for receiving said projection (23b) therein is formed on the peripheral portion of each of said support plate (10), said pump casing (17) and said strainer (20).
5. A submersible pump as claimed in Claim 2, wherein said support plate (10) includes an opening (10a) communicated with said annular flow path (48), a curved discharge guide plate (49) is fixed between said support plate (10) and said pump casing (17) so as to guide a water from said pressure chamber (16) to said annular flow path (48) through said opening (10a) in said support plate (10).
6. A submersible pump comprising: a discharge casing (1) open at the bottom thereof; a motor case (2) fixed inside the discharge casing (1) and containing therein a motor (3) for driving an impeller (15); a support plate (10) positioned so as to close an opening of said discharge casing (1) for supporting said motor case (2); a downwardly concaved pump casing (17) placed under the support plate (10) for defining a pressure chamber (16) between it and the support plate (10); and a downwardly concaved strainer (20) placed under the pump casing (17) for defining a suction chamber (19) between it and the pump casing (17), said discharge casing (1) having a stepped flange (23) of an increased-diameter which is integrally formed along the periphery of an opening thereof, wherein under a partition plate (55) secured to a stepped portion (23a) of the stepped flange (23) there are sequentially mounted re-

spective, peripheral portions of said support plate (10), of said pump casing (17) and of said strainer (20), said submersible pump being characterized in that said motor case (2) has an outwardly extending connection flange (51) formed integral therewith along the lowermost peripheral portion thereof, said connection flange (51) and said support plate (10) are fastened together by third bolts (53) vertically extending therethrough, in that said partition plate (55) is secured to the stepped portion (23a) of the stepped flange (23), and in that said partition plate (55), said support plate (10), said pump casing (17) and said strainer (20) are fastened together by fourth bolts (57) vertically extending therethrough.

7. A submersible pump as claimed in Claim 6, wherein an annular flow path (48) is defined between said discharge casing (1) and said motor case (2) and said third bolts (53) extend vertically through said annular flow path (48).
8. A submersible pump as claimed in Claim 6 or 7, wherein an annular space is defined between said pump casing (17) and said strainer (20) and said fourth bolts (57) extend vertically through said annular space.
9. A submersible pump as claimed in Claim 6 or 7, wherein said partition plate (55) is a ring-shaped one which is secured to said stepped portion (23a) by welding.
10. A submersible pump as claimed in Claim 7, wherein said support plate (10) includes an opening (10a) communicated with said annular flow path (48), the bottom (17b) of said pump casing (17) is bent upwardly to form a discharge guide surface (17c) at the end of said pressure chamber (6), said discharge guide surface (17c) guides a water from said pressure chamber (16) into said annular flow path (48) through said opening (10a) in said support plate (10).
11. A submersible pump as claimed in Claim 6 or 7, wherein a radially inwardly extending projection (23b) is formed on the inner surface of said stepped flange (23), and a groove (24) for receiving said projection (23b) therein is formed on the peripheral portion of each of said support plate (10), said pump casing (17) and said strainer (20).

Patentansprüche

1. Tauchpumpe, die folgendes aufweist: ein Auslaßgehäuse (1), das an dessen Boden offen ist; ein Motorgehäuse (2), das an der Innen-

seite des Auslaßgehäuses (1) befestigt ist und darinnen einen Motor (3) enthält zum Antrieb eines Laufrades (15);

eine Tragplatte (10), die zum Schließen einer Öffnung des Auslaßgehäuses (1) positioniert ist zum Tragen des Motorgehäuses (2); ein nach unten konkav gewölbtes Pumpengehäuse (17), das unter der Tragplatte (10) plaziert ist zum Definieren einer Druckkammer (16) zwischen ihm und der Tragplatte (10); und ein nach unten konkavförmig ausgebildetes Sieb oder Filter (20), der unter dem Pumpengehäuse (14) plaziert ist zum Definieren einer Saugkammer (19) zwischen dem Filter und dem Pumpengehäuse (17), wobei das Auslaßgehäuse (1) einen gestuften Flansch (23) mit vergrößertem Durchmesser besitzt, der integral ausgebildet ist entlang des Umfangs der Öffnung des Auslaßgehäuses (1), wobei innerhalb eines gestuften Teils des gestuften Flansches jeweilige Umfangsteile der Tragplatte, des Pumpengehäuses, und des Filters sequentiell angebracht sind, wobei die Tauchpumpe dadurch gekennzeichnet ist, daß das Auslaßgehäuse (1) und die Tragplatte (10) durch Bolzen oder Schrauben (26) aneinander befestigt sind, die sich vertikal dorthindurch erstrecken und daß die Tragplatte (10) das Pumpengehäuse (17) und der Filter (20) miteinander befestigt sind durch zweite Bolzen oder Schrauben (25), die sich vertikal dorthindurch erstrecken.

2. Tauchpumpe nach Anspruch 1, wobei ein ringförmiger Strömungspfad (48) definiert ist zwischen dem Auslaßgehäuse (1) und dem Motorgehäuse (2) und wobei sich die ersten Bolzen oder Schrauben (26) vertikal durch den ringförmigen Strömungspfad (48) erstrecken.
3. Tauchpumpe nach Anspruch 1 oder 2, wobei ein ringförmiger Raum definiert ist zwischen dem Pumpengehäuse (17) und dem Filter (20) und wobei sich die zweiten Schrauben (25) vertikal durch den ringförmigen Raum erstrecken.
4. Tauchpumpe nach Anspruch 1 oder 2, wobei ein sich radial nach innen erstreckender Vorsprung (23b) an der Innenoberfläche des gestuften Flansches (23) gebildet ist und eine Nut (24) zur Aufnahme des Vorsprungs (23b) darinnen an dem Umfangsteil von jeweils der Tragplatte (10), des Pumpengehäuses (17) und des Filters (20) ausgebildet ist.
5. Tauchpumpe nach Anspruch 2, wobei die Tragplatte (10) eine Öffnung (10a) umfaßt, die in Verbindung steht mit dem ringförmigen Strömungspfad (48), wobei eine gekrümmte Auslaßführungsplatte (49) befestigt ist zwischen der Trag-

platte (10) und dem Pumpengehäuse (17), um Wasser von der Druckkammer (16) zu dem ringförmigen Strömungspfad (48) durch die Öffnung (10a) in der Tragplatte (10) zu lenken oder zu führen.

6. Tauchpumpe, die folgendes aufweist:
 ein Auslaßgehäuse (1), das an dessen Boden offen ist; ein Motorgehäuse (2), das an der Innenseite des Auslaßgehäuses (1) befestigt ist und darinnen einen Motor (3) zum Antrieb eines Lauf-
 5 rades (15) enthält;
 eine Tragplatte (10), die zum Schließen einer Öffnung des Auslaßgehäuses (1) positioniert ist zum Tragen des Motorgehäuses (2);
 ein nach unten konkavförmig gewölbtes Pumpengehäuse (17) plaziert unter der Tragplatte (10) zum Definieren einer Druckkammer (16) zwischen ihm und der Tragplatte (10); und
 10 ein nach unten konkavförmig ausgebildetes Sieb oder ein Filter (20), der unter dem Pumpengehäuse (17) plaziert ist zum Definieren einer Saugkammer (19) zwischen dem Filter und dem Pumpengehäuse (17), wobei das Auslaßgehäuse (1) zwischen gestuften Flansch (23) mit einem vergrößerten Durchmesser besitzt, der integral ausgebildet ist entlang des Umfangs einer Öffnung davon, wobei unter einer Trennplatte (55), die an einem gestuften Teil (23a) des gestuften Flansches (23) befestigt ist, jeweilige Umfangsteile der Trag-
 15 platte (10), des Pumpengehäuses (17) und des Filters (20) sequentiell angebracht sind, wobei die Tauchpumpe dadurch gekennzeichnet ist, daß das Motorgehäuse (2) einen sich nach außen erstreckenden Verbindungsflansch (51) besitzt, der integral damit ausgebildet ist entlang dessen untersten Umfangsteil, wobei der Verbindungsflansch (51) und die Tragplatte (10) miteinander befestigt sind durch dritte Bolzen oder Schrauben (53), die sich vertikal dorthindurch erstrecken, daß die Trennplatte (55) an dem gestuften Teil (23a) des gestuften Flansches (23) befestigt ist, und daß die Trennplatte (55), die Tragplatte (10), das Pumpengehäuse (17) und der Filter (20) miteinander befestigt sind durch vierte Bolzen oder Schrauben (57), die sich vertikal dorthindurch erstrecken.
 20
7. Tauchpumpe nach Anspruch 6, wobei ein ringförmiger Strömungspfad (48) definiert ist zwischen dem Auslaßgehäuse (1) und dem Motorgehäuse (2) und wobei sich die dritten Schrauben (53) vertikal durch den ringförmigen Strömungspfad (48) erstrecken.
 25
8. Tauchpumpe nach Anspruch 6 oder 7, wobei ein ringförmiger Raum definiert ist zwischen dem Pumpengehäuse (17) und dem Filter (20) und wo-
 30

bei sich die vierten Schrauben (57) vertikal durch den ringförmigen Raum erstrecken.

9. Tauchpumpe nach Anspruch 6 oder 7, wobei die Trennplatte (55) ringförmig ist, die an dem gestuften Teil (23a) durch Schweißen befestigt ist.
 35
10. Tauchpumpe nach Anspruch 7, wobei die Tragplatte (10) eine Öffnung (10a) umfaßt, die in Verbindung steht mit dem ringförmigen Strömungspfad (48), wobei der Boden (17b) des Pumpengehäuses (17) nach oben gebogen ist, um eine Auslaßlenk- oder Führungsoberfläche (17c) an dem Ende der Druckkammer (16) zu bilden, wobei die Auslaßführungsoberfläche (17c) Wasser von der Druckkammer (16) in den ringförmigen Strömungspfad (48) lenkt, und zwar durch die Öffnung (10a) in der Tragplatte (10).
 40
11. Tauchpumpe nach Anspruch 6 oder 7, wobei ein sich radial nach innen erstreckender Vorsprung (23b) an der Innenoberfläche des gestuften Flansches (23) gebildet ist und wobei eine Nut (24) zur Aufnahme des Vorsprungs (23b) darinnen ausgebildet ist an dem Umfangsteil von sowohl der Tragplatte (10), dem Pumpengehäuse (17) als auch dem Filter (20).
 45

Revendications

1. Pompe submersible comprenant : un boîtier (1) de refoulement ouvert à sa base ; un boîtier (2) de moteur, fixé à l'intérieur du boîtier (1) de refoulement et contenant intérieurement un moteur (3) destiné à entraîner un rotor (15) ; une plaque support (10) positionnée de manière à fermer une ouverture dudit boîtier (1) de refoulement, pour supporter ledit boîtier (2) de moteur ; un boîtier (17) de pompe, d'une forme concave vers le bas, placé sous la plaque support (10) pour définir une chambre de pression (16) entre lui-même et la plaque support (10) ; et une crépine (20) d'une forme concave vers le bas, placée sous le boîtier (17) de pompe pour définir une chambre d'aspiration (19) entre elle-même et le boîtier (17) de pompe, ledit boîtier (1) de refoulement ayant une bride (23) à gradin de diamètre agrandi qui est venue d'une seule pièce le long de la périphérie de l'ouverture dudit boîtier (1) de refoulement, dans lequel, à l'intérieur de la partie à gradin de ladite bride à gradin, sont montées séquentiellement des parties périphériques respectives de ladite plaque support, dudit boîtier de pompe et de ladite crépine, ladite pompe submersible étant caractérisée en ce que ledit boîtier (1) de refoulement et ladite plaque support (10) sont fixés l'un à l'autre par des premières vis (26) qui les traversent.
 50

sont verticalement et en ce que ladite plaque support (10), ledit boîtier (17) de pompe et ladite crépine (20) sont fixés les uns aux autres par des deuxièmes vis (25) qui les traversent verticalement.

2. Pompe submersible selon la revendication 1, dans laquelle un passage d'écoulement annulaire (48) est défini entre ledit boîtier (1) de refoulement et ledit boîtier (2) de moteur, et lesdites premières vis (26) s'étendent verticalement à travers ledit passage d'écoulement (48).
3. Pompe submersible selon la revendication 1 ou 2, dans laquelle un espace annulaire est défini entre ledit boîtier (17) de pompe et ladite crépine (20), et lesdites deuxièmes vis (25) s'étendent verticalement à travers ledit espace annulaire.
4. Pompe submersible selon la revendication 1 ou 2, dans laquelle une saillie (23b) s'étendant radialement vers l'intérieur est formée sur la surface interne de ladite bride à gradin (23) et une gorge (24) destinée à recevoir intérieurement ladite saillie (23b) est formée sur la partie périphérique de chacun des éléments constitués par ladite plaque support (10), ledit boîtier (17) de pompe et ladite crépine (20).
5. Pompe submersible selon la revendication 2, dans laquelle ladite plaque support (10) comprend une ouverture (10a) qui communique avec ledit passage d'écoulement annulaire (48), une plaque courbe (49) de guidage du refoulement est fixée entre ladite plaque support (10) et ledit boîtier (17) de pompe de manière à guider l'eau de ladite chambre de pression (16) vers ledit passage d'écoulement annulaire (48) en passant par ladite ouverture (10a) de ladite plaque support (10).
6. Pompe submersible comprenant : un boîtier (1) de refoulement ouvert à sa base, un boîtier (2) de moteur fixé à l'intérieur du boîtier (1) de refoulement et contenant intérieurement un moteur (3) destiné à entraîner un rotor (15) ; une plaque support (10) positionnée de manière à fermer une ouverture dudit boîtier (1) de refoulement pour supporter ledit boîtier (2) de moteur ; un boîtier (17) de pompe, d'une forme concave vers le bas, placé sous la plaque support (10) pour définir une chambre de pression (16) entre lui-même et la plaque support (10) ; et une crépine (20) d'une forme concave vers le bas, placée sous le boîtier (17) de pompe pour définir une chambre d'aspiration (19) entre elle-même et le boîtier (17) de pompe, ledit boîtier (1) de refoulement ayant une bride à gradin (23) de diamètre agrandi, qui est

venue d'une seule pièce le long de la périphérie d'une ouverture de ce boîtier, dans laquelle, sous une plaque de séparation (55) fixée à une partie à gradin (23a) de la bride à gradin (23), sont montées séquentiellement des parties périphériques respectives de ladite plaque support (10), dudit boîtier (17) de pompe et de ladite crépine (20), ladite pompe submersible étant caractérisée en ce que ledit boîtier (2) de moteur possède une bride d'assemblage (51) s'étendant vers l'extérieur, venue d'une seule pièce avec lui le long de sa partie périphérique extrême inférieure, ladite bride d'assemblage (51) et ladite plaque support (10) sont fixées l'une à l'autre par des troisièmes vis (53) qui les traversent verticalement, en ce que ladite plaque de séparation (55) est fixée à la partie à gradin (23a) de la bride à gradin (23), et en ce que ladite plaque de séparation (55), ladite plaque support (10), ledit boîtier (17) de pompe et ladite crépine (20) sont fixés ensemble par des quatrièmes vis (57) qui les traversent verticalement.

7. Pompe submersible selon la revendication 6, dans laquelle un passage d'écoulement annulaire (48) est défini entre ledit boîtier (1) de refoulement et ledit boîtier (2) de moteur, et lesdites troisièmes vis (53) s'étendent verticalement à travers ledit passage d'écoulement annulaire (48).
8. Pompe submersible selon la revendication 6 ou 7, dans laquelle un espace annulaire est défini entre ledit boîtier (17) de pompe et ladite crépine (20), et lesdites quatrièmes vis (57) s'étendent verticalement à travers ledit espace annulaire.
9. Pompe submersible selon la revendication 6 ou 7, dans laquelle ladite plaque de séparation (55) est une plaque de forme annulaire, qui est fixée à ladite partie à gradin (23a) par soudage.
10. Pompe submersible selon la revendication 7, dans laquelle ladite plaque support (10) comprend une ouverture (10a) qui communique avec ledit passage d'écoulement annulaire (48), le fond (17b) dudit boîtier (17) de pompe est recourbé vers le haut pour former une surface (17c) de guidage du refoulement à l'extrémité de ladite chambre de pression (16) ladite surface (17c) de guidage du refoulement guide l'eau provenant de ladite chambre de pression (16) dans ledit passage d'écoulement annulaire (48) en passant à travers ladite ouverture (10a) de ladite plaque support (10).
11. Pompe submersible selon la revendication 6 ou 7, dans laquelle une saillie (23b) s'étendant radialement vers l'intérieur est formée sur la surface interne de ladite bride à gradin (23) et une gorge

(24) destinée à recevoir intérieurement ladite saillie (23b) est formée sur la partie périphérique de chacun des éléments constitués par ladite plaque support (10), ledit boîtier (17) de pompe et ladite crépine (20). 5
