BACKGROUND

Technical Field

[002] This disclosure relates to inhibitors of one or more proteins in the Wnt pathway, including inhibitors of one or more Wnt proteins, and compositions comprising the same. More particularly, it concerns the use of an indazole compound or salts or analogs thereof, in the treatment of disorders characterized by the activation of Wnt pathway signaling (e.g., tendinopathy, dermatitis, psoriasis, morphea, ichthyosis, Raynaud's syndrome, Darier's disease, scleroderma, cancer, abnormal cellular proliferation, angiogenesis, Alzheimer's disease, lung disease, fibrotic disorders, cartilage (chondral) defects, and osteoarthritis; and/or for promoting wound healing), the modulation of cellular events mediated by Wnt pathway signaling, as well as genetic diseases and neurological conditions/disorders/diseases due to mutations or dysregulation of the Wnt pathway and/or of one or more of Wnt signaling components. Also provided are methods for treating Wnt-related disease states, as well as neurological conditions/disorders/diseases linked to overexpression of DYRK1A.

Background

[003] The Wnt growth factor family includes more than 10 genes identified in the mouse and at least 19 genes identified in the human. Members of the Wnt family of signaling molecules mediate many short-and long-range patterning processes during invertebrate and vertebrate development. The Wnt signaling pathway is known for its role in the inductive interactions that regulate growth and differentiation, and it also plays roles in the homeostatic maintenance of post-embryonic tissue integrity. Wnt stabilizes cytoplasmic β -catenin, which stimulates the expression of genes including c-myc, c jun, fra-1, and cyclin D1. In addition, misregulation of Wnt signaling can cause developmental defects and is implicated in the genesis of several human cancers. The Wnt pathway has also been implicated in the maintenance of stem

or progenitor cells in a growing list of adult tissues including skin, blood, gut, prostate, muscle, and the nervous system.

[004] Pathological activation of the Wnt pathway is also believed to be the initial event leading to colorectal cancer in over 85% of all sporadic cases in the Western world. Activation of the Wnt pathway has also been extensively reported for hepatocellular carcinoma, breast cancer, ovarian cancer, pancreatic cancer, melanomas, mesotheliomas, lymphomas and leukemias. In addition to cancer, inhibitors of the Wnt pathway can be used for stem cell research or for the treatment of any diseases characterized by aberrant Wnt activation such as diabetic retinopathy, pulmonary fibrosis, rheumatoid arthritis, scleroderma as well as mycotic and viral infections and bone and cartilage diseases. As such, it is a therapeutic target that is of great interest to the field.

[005] In addition to cancer, there are many cases of genetic diseases due to mutations in Wnt signaling components. Examples of some of the many diseases are Alzheimer's disease [*Proc. Natl. Acad. Sci. U S A* (2007), 104(22), 9434-9], osteoarthritis, polyposis coli [*Science* (1991), 253(5020), 665-669], bone density and vascular defects in the eye (osteoporosis-pseudoglioma syndrome, OPPG) [*N. [006] Regulation of cell signaling by the Wnt signaling pathway is critical for the formation of neuronal circuits. Wnt pathway modulates in neural tissue, among other things, axon pathfinding, dendritic development, and synaptic assembly. Through different receptors, Wnt pathway activates and/or regulates diverse signaling pathways and other processes that lead to local changes on the cytoskeleton or global cellular changes involving nuclear function. Recently, a link between neuronal activity, essential for the formation and refinement of neuronal connections, and Wnt signaling has been uncovered. Indeed, neuronal activity regulates the release of various Wnt proteins and the localization of their receptors. Wnt pathway mediates synaptic structural changes induced by neuronal activity or experience. Evidence suggests that dysfunction in Wnt signaling contributes to neurological disorders [*Brain Research Reviews* (2000), 33(1), 1-12; *Oncogene* (2006) 25(57), 7545-7553; *Molecular Neurodegeneration* (2008), 3, 9; *Neurobiology of Disease* (2010), 38(2), 148-153; *Journal of Neurodevelopmental Disorders* (2011), 3(2), 162-174 and *Cold Spring Harbor Perspectives in Biology February* (2012), 4(2)].

[007] Tendinopathies are chronic disorders or injuries of the tendons, that typically result from gradual wear and tear to the tendon, e.g., from overuse or aging, and leading to is tendon degeneration, weakness, tearing, and pain. Individuals who tend to make multiple, repeated motions in their jobs, sports, or regular daily activities tend to be more likely to develop tendinopathies. Tendinopathy usually causes pain, stiffness, and loss of strength in the affected area.

[008] Skin disorders are common afflictions for many people. Some of the most common are dermatitis (also known as eczema) and psoriasis. Both dermatitis and psoriasis can cause serious physical and/or psychological suffering to the subject regardless of the location on the body that these conditions occur.

[009] Dual specificity tyrosine-phosphorylation-regulated kinase 1A is an enzyme that in humans is encoded by the DYRK1A gene. DYRK1A is a member of the dual-specificity tyrosine phosphorylation-regulated kinase (DYRK) family. DYRK1A contains a nuclear targeting signal sequence, a protein kinase domain, a leucine zipper motif, and a highly conservative 13-consecutive-histidine repeat. It catalyzes its autophosphorylation on serine/threonine and tyrosine residues. It may play a significant role in a signaling pathway regulating cell proliferation and may be involved in brain development. DYRK1A is localized in the Down syndrome critical region of chromosome 21, and is considered to be a candidate gene for learning defects associated with Down syndrome. DYRK1A is also expressed in adult brain neurons, indicating that DYRK1A may play a role in the mature central nervous system. Thus, several lines of evidence point to some synaptic

functions of DYRK1A. For instance, it has been found that DYRK1A phosphorylates and modulates the interaction of several components of the endocytic protein complex machinery (Dynamin 1, Amphiphysin, and Synaptojanin), suggesting a role in synaptic vesicle recycling. In addition, a polymorphism (SNP) in DYRK1A was found to be associated with HIV-1 replication in monocyte-derived macrophages, as well as with progression to AIDS in two independent cohorts of HIV-1-infected individuals.

The combination of compounds can be a synergistic combination. Synergy, as described, for example, by Chou and Talalay, *Advances in Enzyme Regulation* (1984), 22, 27-55, occurs when the effect of the compounds when administered in combination is greater than the additive effect of the compounds when administered alone as a single agent. In general, a synergistic effect is most clearly demonstrated at sub-optimal concentrations of the compounds. It will be appreciated that different concentrations may be employed for prophylaxis than for treatment of an active disease. Tendinopathy includes, for example, inflammation of the tendon (e.g., tendonitis), non-inflammatory degeneration of, for example, the structure and/or composition of a tendon (e.g., tendinosis), inflammation of the paratenon near or in contact with a tendon (e.g., paratenonitis), micro-trauma to the tendon, and rupture of the tendon (e.g., acute, chronic, partial and/or complete rupture). The term also encompasses tenosynovitis, a tendinopathy of the outer lining of the tendon which occurs in certain tendons such as flexor tendons and the Achilles tendon. Symptoms of tendinopathy include pain at rest, upon palpation of the tendon, and/or with movement of, for example, the tendon, tissue, joint, or bone near or associated with the tendon; joint stiffness; difficulty moving; weakness of the joint or muscles surrounding the tendon; redness of the skin near the tendon; swelling of the tendon and/or of tissue near the tendon; and/or crepitus.

Degeneration of the tendon is caused by damage to or disorganization of the collagen fibers, cells, and vascular components of the tendon, which can reduce the tendon's tensile strength and can lead to tendon rupture if not treated.

[075] "Tendinitis" as used herein refers to an inflammatory injury to the tendon, characterized by degeneration like that observed in tendinosis, but also accompanied by inflammation of the tendon, vascular disruption and an inflammatory repair response. Tendinitis is often associated with fibroblastic and myofibroblastic proliferation, as well as hemorrhage and organizing granulation tissue. Generally, tendinitis is referred to by the body part involved, such as Achilles tendinitis (affecting the Achilles tendon), or patellar tendinitis (also known as "jumper's knee," affecting the patellar tendon), though there are certain exceptions, such as lateral epicondylitis (also known as "tennis elbow," affecting the Extensor Carpi Radialis Brevis tendon).

Symptoms can vary from aches or pains and local stiffness to a burning sensation surrounding the entire joint around the inflamed tendon. In some cases, tendonitis is characterized by swelling, sometimes accompanied by heat and redness; there may also be visible knots surrounding the joint. For many patients, the pain is usually worse during and after activity, and the tendon and joint area can become stiffer the following day as muscles tighten from the movement of the tendon.

[076] “Psoriasis” as used herein refers to an autoimmune disease in which skin cells build up and causes raised, red, scaly patches to appear on the skin.

[077] “Dermatitis” (also known as eczema) as used herein refers to generic inflammation of the skin. Specific types of dermatitis include atopic, contact, nummular, photo-induced, and stasis dermatitis. These diseases are characterized by itchiness, red skin, and a rash.

[078] “Drug-eluting” and/or controlled release as used herein refers to any and all mechanisms, e.g., diffusion, migration, permeation, and/or desorption by which the drug(s) incorporated in the drug-eluting material pass therefrom over time into the surrounding body tissue.

[079] “Drug-eluting material” and/or controlled release material as used herein refers to any natural, synthetic or semi-synthetic material capable of acquiring and retaining a desired shape or configuration and into which one or more drugs can be incorporated and from which incorporated drug(s) are capable of eluting over time.

[080] “Elutable drug” as used herein refers to any drug or combination of drugs having the ability to pass over time from the drug-eluting material in which it is incorporated into the surrounding areas of the body.

[0266] In one embodiment, the compositions can be administered to the respiratory tract (including nasal and pulmonary) e.g., through a nebulizer, metered-dose inhalers, atomizer, mister, aerosol, dry powder inhaler, insufflator, liquid instillation or other suitable device or technique.

[0267] In some embodiments, aerosols intended for delivery to the nasal mucosa are provided for inhalation through the nose. For optimal delivery to the nasal cavities, inhaled particle sizes of about 5 to about 100 microns are useful, with particle sizes of about 10 to about 60 microns being preferred. For nasal delivery, a larger inhaled particle size may be desired to maximize impaction on the nasal mucosa and to minimize or prevent pulmonary deposition of the administered formulation. In some embodiments, aerosols intended for delivery to the lung are provided for inhalation through the nose or the mouth. For delivery to the lung, inhaled aerodynamic particle sizes of about less than 10 µm are useful (e.g., about 1 to about 10 microns). Inhaled particles may be defined as liquid droplets containing dissolved drug, liquid droplets containing suspended drug particles (in cases where the drug is insoluble in the suspending medium), dry particles of pure drug substance, drug substance incorporated with excipients,

liposomes, emulsions, colloidal systems, coacervates, aggregates of drug nanoparticles, or dry particles of a diluent which contain embedded drug nanoparticles.

[0268] In some embodiments, compounds of Formula (I) disclosed herein intended for respiratory delivery (either systemic or local) can be administered as aqueous formulations, as non-aqueous solutions or suspensions, as suspensions or solutions in halogenated hydrocarbon propellants with or without alcohol, as a colloidal system, as emulsions, coacervates, or as dry powders. Aqueous formulations may be aerosolized by liquid nebulizers employing either hydraulic or ultrasonic atomization or by modified micropump systems (like the soft mist inhalers, the Aerodose[®] or the AERx[®] systems). Propellant-based systems may use suitable pressurized metered-dose inhalers (pMDIs). Dry powders may use dry powder inhaler devices (DPIs), which are capable of dispersing the drug substance effectively. A desired particle size and distribution may be obtained by choosing an appropriate device.

[0269] In some embodiments, the compositions of Formula (I) disclosed herein can be administered to the ear by various methods. For example, a round window catheter (e.g., U.S. Pat. Nos. 6,440,102 and 6,648,873) can be used.

[0270] Alternatively, formulations can be incorporated into a wick for use between the outer and middle ear (e.g., U.S. Pat. No. 6,120,484) or absorbed to collagen sponge or other solid support (e.g., U.S. Pat. No. 4,164,559).

[0271] If desired, formulations of the disclosure can be incorporated into a gel formulation (e.g., U.S. Pat. Nos. 4,474,752 and 6,911,211).

[0272] In some embodiments, compounds of Formula (I) disclosed herein intended for delivery to the ear can be administered via an implanted pump and delivery system through a needle directly into the middle or inner ear (cochlea) or through a cochlear implant stylet electrode channel or alternative prepared drug delivery channel such as but not limited to a needle through temporal bone into the cochlea.

[0273] Other options include delivery via a pump through a thin film coated onto a multichannel electrode or electrode with a specially imbedded drug delivery channel (pathways) carved into the thin film for this purpose. In other embodiments the acidic or basic solid compound of Formula (I) can be delivered from the reservoir of an external or internal implanted pumping system.

[0274] Formulations of the disclosure also can be administered to the ear by intratympanic injection into the middle ear, inner ear, or cochlea (e.g., U.S. Pat. No. 6,377,849 and Ser. No. 11/337,815).

[0275] Intratympanic injection of therapeutic agents is the technique of injecting a therapeutic agent behind the tympanic membrane into the middle and/or inner ear. In one embodiment, the formulations described herein are administered directly onto the round window membrane via transtympanic injection. In another embodiment, the ion channel modulating agent auris-acceptable formulations described herein are administered onto the round window membrane via a non-transtympanic approach to the inner ear. In additional embodiments, the formulation described herein is administered onto the round window membrane via a surgical approach to the round window membrane comprising modification of the crista fenestrae cochleae.

[0276] In some embodiments, the compounds of Formula (I) are formulated in rectal compositions such as enemas, rectal gels, rectal foams, rectal aerosols, suppositories, jelly suppositories, or retention enemas, containing conventional suppository bases such as cocoa butter or other glycerides, as well as synthetic polymers such as polyvinylpyrrolidone, PEG (like PEG ointments), and the like.

[0277] Suppositories for rectal administration of the drug (either as a solution, colloid, suspension or a complex) can be prepared by mixing a compound provided herein with a suitable non-irritating excipient that is solid at ordinary temperatures but liquid at the rectal temperature and will therefore melt or erode/dissolve in the rectum and release the compound. Such materials include cocoa butter, glycerinated gelatin, hydrogenated vegetable oils, poloxamers, mixtures of polyethylene glycols of various molecular weights and fatty acid esters of polyethylene glycol. In suppository forms of the compositions, a low-melting wax such as, but not limited to, a mixture of fatty acid glycerides, optionally in combination with cocoa butter, is first melted.

[0278] In some embodiments, the compositions can be administered by transdermal patch.

[0279] Other modes of deliveries include using biodegradable or non-biodegradable scaffolds.

[0280] It is to be noted that concentrations and dosage values may also vary with the severity of the condition to be alleviated. It is to be further understood that for any particular patient, specific dosage regimens should be adjusted over time according to the individual need and the professional judgment of the person administering or supervising the administration of the compositions, and that the concentration ranges set forth herein are exemplary only and are not intended to limit the scope or practice of the claimed compositions.

[0281] Solid compositions can be provided in various different types of dosage forms, depending on the physicochemical properties of the compound provided herein, the desired dissolution rate, cost considerations, and other criteria. In one of the embodiments, the solid

composition is a single unit. This implies that one unit dose of the compound is comprised in a single, physically shaped solid form or article. In other words, the solid composition is coherent, which is in contrast to a multiple unit dosage form, in which the units are incoherent.

[0282] Examples of single units which may be used as dosage forms for the solid composition include tablets, such as compressed tablets, film-like units, foil-like units, wafers, lyophilized matrix units, and the like. In one embodiment, the solid composition is a highly porous lyophilized form. Such lyophilizates, sometimes also called wafers or lyophilized tablets, are particularly useful for their rapid disintegration, which also enables the rapid dissolution of the compound.

[0283] On the other hand, for some applications the solid composition may also be formed as a multiple unit dosage form as defined above. Examples of multiple units are powders, granules, microparticles, pellets, mini-tablets, beads, lyophilized powders, and the like. In one embodiment, the solid composition is a lyophilized powder. Such a dispersed lyophilized system comprises a multitude of powder particles, and due to the lyophilization process used in the formation of the powder, each particle has an irregular, porous microstructure through which the powder is capable of absorbing water very rapidly, resulting in quick dissolution. Effervescent compositions are also contemplated to aid the quick dispersion and absorption of the compound.

[0284] Another type of multiparticulate system which is also capable of achieving rapid drug dissolution is that of powders, granules, or pellets from water-soluble excipients which are coated with a compound provided herein so that the compound is located at the outer surface of the individual particles. In this type of system, the water-soluble low molecular weight excipient may be useful for preparing the cores of such coated particles, which can be subsequently coated with a coating composition comprising the compound and, for example, one or more additional excipients, such as a binder, a pore former, a saccharide, a sugar alcohol, a film-forming polymer, a plasticizer, or other excipients used in pharmaceutical coating compositions.

[0285] Also provided herein are kits. Typically, a kit includes one or more compounds or compositions as described herein. In certain embodiments, a kit can include one or more delivery systems, e.g., for delivering or administering a compound as provided herein, and directions for use of the kit (e.g., instructions for treating a patient). In another embodiment, the kit can include a compound or composition as described herein and a label that indicates that the contents are to be administered to a patient with cancer. [0471] Moreover, the compounds and compositions, for example, as inhibitors of the cyclin-dependent kinases (CDKs), can modulate the level of cellular RNA and DNA synthesis and therefore are expected to be useful in the treatment of viral infections such as HIV, human papilloma virus, herpes virus, Epstein-Barr virus, adenovirus, Sindbis virus, pox virus and the like.

[0472] Compounds and compositions described herein can inhibit the kinase activity of, for example, CDK/cyclin complexes, such as those active in the G₀ or G₁ stage of the cell cycle, e.g., CDK2, CDK4, and/or CDK6 complexes.

Evaluation of Biological Activity

[0473] The biological activity of the compounds described herein can be tested using any suitable assay known to those of skill in the art, see, e.g., WO 2001/053268 and WO 2005/009997. For example, the activity of a compound may be tested using one or more of the test methods outlined below.

[0474] In one example, tumor cells may be screened for Wnt independent growth. In such a method, tumor cells of interest are contacted with a compound (i.e. inhibitor) of interest, and the proliferation of the cells, e.g. by uptake of tritiated thymidine, is monitored. In some

embodiments, tumor cells may be isolated from a candidate patient who has been screened for the presence of a cancer that is associated with a mutation in the Wnt signaling pathway. Candidate cancers include, without limitation, those listed above.

[0475] In another example, one may utilize *in vitro* assays for Wnt biological activity, e.g. stabilization of β -catenin and promoting growth of stem cells. Assays for biological activity of Wnt include stabilization of β -catenin, which can be measured, for example, by serial dilutions of a candidate inhibitor composition. An exemplary assay for Wnt biological activity contacts a candidate inhibitor with cells containing constitutively active Wnt/ β -catenin signaling. The cells are cultured for a period of time sufficient to stabilize β -catenin, usually at least about 1 hour, and lysed. The cell lysate is resolved by SDS PAGE, then transferred to nitrocellulose and probed with antibodies specific for β -catenin.

[0476] In a further example, the activity of a candidate compound can be measured in a *Xenopus* secondary axis bioassay (Leyns, L. *et al. Cell* (1997), 88(6), 747-756).

[0477] In another example, *in vitro* assays for DYRK1A biological activity may be used, e.g. regulation of microtubule-associated protein tau (MAPT/Tau) phosphorylation in neuronal cell line such as the human SH-SY5Y neuroblastoma cell line. Assays for DYRK1A-regulated level of phosphorylation can include monitoring levels of basal pSer396 Tau, which can be measured, for example, by serial dilutions of a candidate inhibitor composition using a ten micromolar top concentration and detected by ELISA or Western Blotting. An exemplary assay for DYRK-1A-regulated phosphorylation uses the SH-SY5Y cells cultured in a 96 well plate format for a period of time sufficient to stabilize microtubules and Tau phosphorylation, usually at least 2 days, then treated with a 1/3 serial dilution of compounds overnight and lysed. The cell lysate is resolved by SDS PAGE, then transferred to nitrocellulose and probed with an antibody specific for pSer396 Tau. The chemiluminescence signal for HRP-linked antibodies used in western blotting is detected using a Carestream Image Station and blot densitometry for pSer396 and beta-actin are analyzed using ImageJ (NIH).

[0478] In a further example, the activity of a candidate compound can be measured by ELISA by adding the lysate mentioned above onto total Tau-coated plates and detected with a specific pSer396 antibody. Colorimetric detection of ELISA signal is performed by Cytation3 plate reader (Biotek).

General procedures

[0487] Compounds of Formula I of the present disclosure can be prepared as depicted in Scheme 1.

Scheme 1

[0488] Scheme 1 describes a method for preparation of indazole-3-carboxamide derivatives (I) by first forming the Weinreb amide (III) of a 1H-indazole-3-carboxylic acid (II). The Weinreb amide (III) is reacted with bis(trifluoroacetoxy)iodobenzene to produce the 5-iodo-1H-indazole-3-carboxylic acid (IV) followed by THP protection of the indazole nitrogen. The Weinreb amide of protected indazole V is reduced to aldehyde VI followed by reaction with bis(pinacolato)diboron to give the pinacol ester (VII). Suzuki coupling with a variety of aromatic

and nonaromatic bromides yields the R³ substituted indazole VIII. Oxidation of the aldehyde to the acid (IX) followed by HATU mediated coupling of a variety of amines and sequent deprotection produces the desired indazole-3-carboxamide derivatives (I).

[0489] Compounds of Formula I of the present disclosure can also be prepared as depicted in Scheme 2.

[0490] Scheme 2 describes an alternative method for preparation of indazole-3-carboxamide derivatives (I) by bromination of the indazole 5-position followed by esterification to form ester XII. The indazole nitrogen is THP protected and the ester is hydrolyzed to acid XIV. The acid is coupled with a variety of amines to produce amide XV which is then coupled with a variety of boronic acids (Route 1) to give X. Alternatively, XV can be converted to the boronate ester and then couple to a variety of bromides (Route 2) to yield X. Final deprotection of the indazole nitrogen yields the desired indazole-3-carboxamide derivatives (I).

[0491] Compounds of Formula I of the present disclosure can also be prepared as depicted in Scheme 3.

Scheme 3

[0492] Scheme 3 describes another alternative method for preparation of indazole-3-carboxamide derivatives (I) by bromination of the indazole 5-position followed by either Route 1: esterification to form ester XII, then trityl protection of the indazole nitrogen and then finally hydrolyzed of the ester to acid XVII; or Route 2: trityl protection of the indazole nitrogen directly to acid XVII. The acid is coupled with a variety of amines to produce amide XVIII which is then coupled with a variety of boronic acids (Route 3) to give XIX. Alternatively, XVIII can be converted to the boronate ester and then couple to a variety of bromides (Route 4) to yield XIX. Final deprotection of the indazole nitrogen yields the desired indazole-3-carboxamide derivatives (I).

[0493] The following are commercially available intermediates.

Example 3.

[0876] The screening assay for Wnt activity is described as follows. Reporter cell lines can be generated by stably transducing cancer cell lines (e.g., colon cancer) or primary cells (e.g., IEC-6 intestinal cells) with a lentiviral construct that includes a Wnt-responsive promoter driving expression of the firefly luciferase gene.

[0877] SW480 colon carcinoma cells were transduced with a lentiviral vector expressing luciferase with a human Sp5 promoter consisting of a sequence of eight TCF/LEF binding sites. SW480 cells stably expressing the Sp5-Luc reporter gene and a hygromycin resistance gene were selected by treatment with 150 µg/mL of hygromycin for 7 days. These stably transduced SW480 cells were expanded in cell culture and used for all further screening activities. Each compound was dissolved in DMSO as a 10 mM stock and used to prepare compound source plates. Serial dilution (1:3, 10-point dose-response curves starting from 10 µM) and compound transfer was performed using the ECHO 550 (Labcyte, Sunnyvale, CA) into 384-well white solid bottom assay plates (Greiner Bio-One) with appropriate DMSO backfill for a final DMSO concentration of 0.1%. For Sp5-Luc reporter gene assays, the cells were plated at 4,000 cells/well in 384-well plates with a DMEM medium containing 1% fetal bovine serum, and 1% Penicillin-Streptomycin and incubated for 36 to 48 hours at 37°C and 5% CO₂. Following incubation, 15 µl of BriteLite Plus luminescence reagent (Perkin Elmer) was added to each well of the 384-well assay plates. The plates were placed on an orbital shaker for 2 min and then luminescence was quantified

using the Envision (Perkin Elmer) plate reader. Readings were normalized to DMSO only treated cells, and normalized activities were utilized for EC₅₀ calculations using the dose-response log (inhibitor) vs. response –variable slope (four parameters) nonlinear regression feature available in GraphPad Prism 5.0 (or Dotmatics). For EC₅₀ of >10 μ M, the percent inhibition at 10 μ M is provided.

[0878] Table 2 shows the measured activity for representative compounds of Formula I as described herein.

Example 4.

[0879] Representative compounds were screened using the assay procedure for DYRK1A kinase activity as described below.

[0880] Each compound was dissolved in DMSO as a 10 mM stock and used to prepare compound source plates. Serial dilution (1:3, 11-point dose-response curves from 10 μ M to 0.00016

μM) and compound transfer was performed using the ECHO 550 (Labcyte, Sunnyvale, CA) into 1536-well black-walled round bottom plates (Corning).

[0881] The DYRK1A kinase assay was run using the Ser/Thr 18 peptide Z-lyte assay kit according to manufacturer's instructions (Life Technologies- a Division of Thermo-Fisher). This is a non-radioactive assay using fluorescence resonance energy transfer (FRET) between coumarin and fluorescein to detect kinase activity which is represented as a ratio of coumarin emission/fluorescein emission.

[0882] Briefly, recombinant DYRK1A kinase, ATP and Ser/Thr peptide 18 were prepared in 1X Kinase buffer to final concentrations of 0.19 μg/mL, 30 μM, and 4 μM respectively. The mixture was allowed to incubate with the representative compounds for one hour at room temperature. All reactions were performed in duplicate. Unphosphorylated ("0% Control") and phosphorylated ("100% control") forms of Ser/Thr 18 served as control reactions. Additionally, an 11-point dose-response curve of Staurosporine (1μM top) was run to serve as a positive compound control.

[0883] After incubation, Development Reagent A was diluted in Development Buffer then added to the reaction and allowed to further incubate for one hour at room temperature. The plate was read at Ex 400 Em 455 to detect the coumarin signal and Ex 400 Em 520 to measure the signal (EnVision Multilabel Plate Reader, PerkinElmer).

[0884] The Emission ratio (Em) was calculated as a ratio of the coumarin (C) emission signal (at 445 nm)/Fluorescein (F) emission signal (at 520 nm). The percent phosphorylation was then calculated using the following formula: $[1 - ((\text{Em ratio} \times \text{F100\%}) - \text{C100\%}) / ((\text{C0\%} - \text{C100\%}) + (\text{Em ratio} \times (\text{F100\%} - \text{F0\%})))]$. Dose-response curves were generated and inhibitory concentration (IC₅₀) values were calculated using non-linear regression curve fit in the Dotmatics' Studies Software (Bishops Stortford, UK).

[0885] Table 3 shows the measured activity for representative compounds of Formula I as described herein.

Example 5.

[0886] Representative compounds were screened using the assay procedure for GSK3 β kinase activity as described below.

[0887] Each compound is dissolved in DMSO as a 10 mM stock and used to prepare compound source plates. Serial dilution (1:3, 11-point dose-response curves from 10 μ M to 0.0003 μ M) and compound transfer was performed using the ECHO 550 (Labcyte, Sunnyvale, CA) into 1536-well black-walled round bottom plates (Corning).

[0888] The GSK3 β kinase assay is run using the Ser/Thr 09 peptide Z-lyte assay kit according to manufacturer's instructions (Life Technologies- a Division of Thermo-Fisher). This is a non-radioactive assay using fluorescence resonance energy transfer (FRET) between coumarin and fluorescein to detect kinase activity which is represented as ratio of coumarin emission/fluorescein emission.

[0889] Briefly, recombinant GSK3 β kinase, ATP and Ser/Thr peptide 09 are prepared in 1X Kinase buffer to final concentrations of 0.04 μ g/mL, 46 μ M, and 4 μ M respectively. The mixture is allowed to incubate with the representative compounds for one hour at room temperature. All reactions were performed in duplicate. Unphosphorylated ("0% Control") and phosphorylated ("100% control") forms of Ser/Thr 18 serve as control reactions.

[0890] After incubation, diluted Development Buffer is added to the reaction and allowed to further incubate for one hour at room temperature. The plate is read at Ex 400 Em 455

to detect the coumarin signal and Ex 400 Em 520 to measure the signal (EnVision Multilabel Plate Reader, PerkinElmer).

[0891] The Emission ratio (Em) is calculated as a ratio of the coumarin (C) emission signal (at 445 nm)/Fluorescein (F) emission signal (at 520 nm). The percent phosphorylation is then calculated using the following formula: $[1 - ((\text{Em ratio} \times \text{F100\%}) - \text{C100\%}) / ((\text{C0\%} - \text{C100\%}) + (\text{Em ratio} \times (\text{F100\%} - \text{F0\%})))]$.

[0892] Dose-response curves are generated and inhibitory concentration (IC₅₀) values are calculated using non-linear regression curve fit in the Dotmatics' Studies Software (Bishops Stortford, UK).

Example 6.

[0894] Representative compounds were screened using the assay procedure to assess the effect on cell viability as described below.

[0895] SW480 colon carcinoma cells were transduced with a lentiviral vector expressing luciferase with a human Sp5 promoter consisting of a sequence of eight TCF/LEF binding sites. SW480 cells stably expressing the Sp5-Luc reporter gene and a hygromycin resistance gene were selected by treatment with 150 µg/mL of hygromycin for 7 days. These stably transduced SW480 cells were expanded in cell culture and used for all further screening activities. Each compound was dissolved in DMSO as a 10 mM stock and used to prepare compound source plates. Serial dilution (1:3, 8-point dose-response curves from 10 µM to 0.0045 µM) and compound transfer was performed using the ECHO 550 (Labcyte, Sunnyvale, CA) into 384-well white solid bottom assay plates (Greiner Bio-One) with appropriate DMSO backfill for a final DMSO concentration of 0.1%.

[0896] For the Cell Viability Assays, the cells were plated at 2,000 cells/well in 384-well plates with a DMEM medium containing 1% fetal bovine serum, and 1% Penicillin-Streptomycin and incubated for four days hours at 37°C and 5% CO₂. Eight replicates of DMSO-treated cells served as controls and cells treated with compound were performed in duplicate.

[0897] After incubation, 10 µL of CellTiter-Glo (Promega) was added to each well allowed to incubate for approximately 12 minutes. This reagent “results in cell lysis and generation of a luminescent signal proportional to the amount of ATP present. The amount of ATP is directly proportional to the number of cells present in culture, in agreement with previous reports. The CellTiter-Glo® Assay generates a "glow-type" luminescent signal, produced by the luciferase reaction (Promega.com)”.

[0898] After incubation, the plates were read at Ex 560 nm Em 590 nm (Cytation 3, BioTek). Dose-response curves were generated and EC₅₀ concentration values were calculated using non-linear regression curve fit in the GraphPad Prism (San Diego, CA) or Dotmatics' Studies Software (Bishops Stortford, UK). For EC₅₀ of >10 µM, the percent inhibition at 10 µM is provided.

[0899] Table 5 shows the activity of representative compounds of Formula I as provided herein.

Example 7.

[0900] Representative compounds were screened using primary human fibroblasts (derived from IPF patients) treated with TGF- β 1 to determine their ability to inhibit the fibrotic process.

[0901] *Human Fibroblast Cell Culture:* Primary human fibroblasts derived from IPF patients (LL29 cells) [¹Xiaoqiu Liu, et.al., “Fibrotic Lung Fibroblasts Show Blunted Inhibition by cAMP Due to Deficient cAMP Response Element-Binding Protein Phosphorylation”, *Journal of Pharmacology and Experimental Therapeutics* (2005), 315(2), 678-687; ²Watts, K. L., et.al., “RhoA signaling modulates cyclin D1 expression in human lung fibroblasts; implications for idiopathic pulmonary fibrosis”, *Respiratory Research* (2006), 7(1), 88] were obtained from American Type Culture Collection (ATCC) and expanded in F12 medium supplemented with 15% Fetal Bovine Serum and 1% Penicillin/Streptomycin.

[0902] *Compound Screening:* Each compound was dissolved in DMSO as a 10 mM stock and used to prepare compound source plates. Serial dilution (1:2, 11-point dose-response curves from 10 μ M to 0.94 nM) and compound transfer was performed using the ECHO 550 (Labcyte, Sunnyvale, CA) into 384-well clear bottom assay plates (Greiner Bio-One) with appropriate DMSO backfill for a final DMSO concentration of 0.1%. LL29 cells were plated at

1,500 cells/well in 70 μ L/well F12 medium supplemented with 1% Fetal Bovine Serum. TGF- β 1 (Peprotech; 20 ng/mL) was added to the plates to induce fibrosis (ref. 1 and 2 above). Wells treated with TGF- β 1 and containing DMSO were used as positive control, and cells with only DMSO were negative control. Cells were incubated at 37°C and 5% CO₂ for 4 days. Following incubation for 4 days, SYTOX green nucleic acid stain (Life Technologies [Thermo Fisher Scientific]) was added to the wells at a final concentration of 1 μ M and incubated at room temperature for 30 min. Cells were then fixed using 4% formaldehyde (Electron Microscopy Sciences), washed 3 times with PBS followed by blocking and permeabilization using 3% Bovine Serum Albumin (BSA; Sigma) and 0.3% Triton X-100 (Sigma) in PBS. Cells were then stained with antibody specific to α -smooth muscle actin (α SMA; Abcam) (ref. 1 and 2 above) in 3% Bovine Serum Albumin (BSA; Sigma) and 0.3% Triton X-100 (Sigma) in PBS, and incubated overnight at 4°C. Cells were then washed 3 times with PBS, followed by incubation with Alexa Fluor-647 conjugated secondary antibody (Life Technologies [Thermo Fisher Scientific]) and DAPI in 3% Bovine Serum Albumin (BSA; Sigma) and 0.3% Triton X-100 (Sigma) in PBS at room temperature for 1 hour. Cells were then washed 3 times with PBS and plates were sealed for imaging. α SMA staining was imaged by excitation at 630 nm and emission at 665 nm and quantified using the Compartmental Analysis program on the CellInsight CX5 (Thermo Scientific). Dead or apoptotic cells were excluded from analysis based on positive SYTOX green staining. % of total cells positive for α SMA were counted in each well and normalized to the average of 11 wells treated with TGF- β 1 on the same plate using Dotmatics' Studies Software. The normalized averages (fold change over untreated) of 3 replicate wells for each compound concentration were used to create dose-responses curves and EC₅₀ values were calculated using non-linear regression curve fit in the Dotmatics' Studies Software. For EC₅₀ of >10 μ M, the percent inhibition at 10 μ M is provided.

Example 8.

[0904] Representative compounds were screened using the following assay procedure to determine their ability to inhibit IL-6 and therefore demonstrate their anti-inflammatory properties.

[0905] *Human Peripheral Blood Mononuclear Cells:* Fresh Normal PB MNC (Catalog # PB001, AllCells, Alameda, CA) were shipped overnight at 4°C and resuspended in Roswell Park Memorial Institute (RPMI) 1640 Medium, with GlutaMAX Supplement (Catalog #61870127, ThermoFisher Scientific, Waltham, MA) supplemented with 1% Penicillin-Streptomycin (Catalog# 15140163, ThermoFisher Scientific, Waltham, MA) and 1% fetal bovine serum (FBS) (Catalog # 16140089, ThermoFisher Scientific, Waltham, MA) assay media.

[0906] *Compound Screening:* Fresh normal human peripheral blood mononuclear cells (huPBMCs) were resuspended in 1% FBS-RPMI assay media with 1% Penicillin-Streptomycin 1% to a cell concentration of 1×10^6 cells/mL. Each compound was dissolved in DMSO (Catalog # D8418-100ml, Sigma-Aldrich, St. Louis, MO) as a 10 mM stock and used to prepare compound source plates. Serial dilution (1:3, 10-point dose-response curves starting from 10 μ M) and compound transfer was performed using the ECHO 550 (Labcyte, Sunnyvale, CA) into 384-well white Proxiplate-Plus assay plates (Catalog #6008289, PerkinElmer, Shelton, CT) with appropriate DMSO backfill for a final DMSO concentration of 0.25%. huPBMCs were plated at 5000 cells/well in the 384-well Proxiplate-Plus assay plates and incubated at 37°C-5% CO₂ for 2 hours. 50 ng/mL of Lipopolysaccharides from Escherichia coli 0111:B4 (Catalog #L5293-2ML,

Sigma-Aldrich, St. Louis, MO) was added after 2 hours and cells were incubated for another 22 hours at 37°C-5% CO₂. After 22 hour incubation, a mixture of anti-IL6 XL665 and anti-IL-6 Cryptate diluted in reconstitution buffer (Catalog #62IL6PEC, Cisbio Inc., Bedford, MA) was added to each well. Following incubation for 3 hours at room temperature, Homogeneous Time-Resolved Fluorescence (HTRF) was measured using the Envision (Perkin Elmer, Shelton, CT) at 665 nm and 620 nm. The ratio of fluorescence at 665 nm to 620 nm was used as a readout for IL-6 quantification. All samples were processed in duplicate. Readings were normalized to DMSO treated cells and normalized activities were utilized for EC₅₀ calculations. EC₅₀ was determined using software generated by Dotmatics Limited (Windhill Bishops Stortford Herts, UK) using the Levenberg-Marquardt 4 parameter fitting procedure with finite different gradients. For EC₅₀ of >10 μM, the percent inhibition at 10 μM is provided.

Example 9.

[0908] Representative compounds were screened using primary human mesenchymal stem cells (hMSCs) to determine their ability to induce tenocyte differentiation (process by which tendon is developed).

[0909] *Human Mesenchymal Stem Cell Culture:* Primary human mesenchymal stem cells (hMSCs) were purchased from Lonza (Walkersville, MD) and expanded in Mesenchymal Stem Cell Growth Media (Lonza). Cells between passage 3 and 6 were used for the experiments.

[0910] *Compound Screening:* Each compound was dissolved in DMSO as a 10mM stock and used to prepare compound source plates. For the tenocyte differentiation assay, serial dilution (1:2, 10-point dose-response curves from 10 μ M to 19.5 nM) and compound transfer was performed using the ECHO 550 (Labcyte, Sunnyvale, CA) into 384-well black clear bottom assay plates (Greiner Bio-One) with appropriate DMSO backfill for a final DMSO concentration of 0.17%. hMSCs were plated at 3,000 cells/well in 70 μ L/well Dulbecco's modified Eagle's medium (DMEM, Life Technologies, Carlsbad, CA) with 1% Fetal Bovine Serum (FBS, Life Technologies). Bone Morphogenic Factor (BMP) and Fetal Growth Factor (FGF) (10 ng/ml each, Peprotech, Inc., Rocky Hill, NJ) were used as a positive-controls for differentiation while negative control wells were treated with 120 nL DMSO for normalization and calculating EC₅₀ values. Cells were incubated at 37°C and 5% CO₂ for 4 days. Cells were fixed using 4% formaldehyde (Electron Microscopy Sciences), and stained with anti-Scleraxis (anti-SCXA) antibodies (Abgent, San Diego, CA) [Webb S., *et.al.*, Retinoic acid receptor signaling preserves tendon stem cell characteristics and prevents spontaneous differentiation *in vitro*, *Stem Cell Research & Therapy* 2016, 7:45] overnight at 4°C. The cells were washed with Phosphate Buffered Saline (PBS, Life Technologies) and incubated with anti-rabbit Alexa-flor 647 secondary antibodies (Life Technologies) and DAPI (Life Technologies) for 1 hour at room temperature. Cells were washed using PBS, and imaged using the CellInsight CX5 (Life Technologies, 594/633nm filter). Number of cells positive for SCXA in each well was quantified using the CellInsight CX5. Data was normalized to the average

of 12 DMSO treated wells on the same plate using Dotmatics Studies module. The normalized averages (fold change over DMSO) of 3 replicate wells for each compound concentration were calculated. Due to solubility limitations of some of the compounds, values for higher doses were manually corrected and curve fitting and EC₅₀ determinations were performed using Dotmatics Studies.
