The present invention relates to compounds of general formula I, to pharmaceutical composition containing them and their use in the treatment of neurological and neuropsychiatric disorders. It has surprisingly been found that the compounds of general formula I are good inhibitors of the glycine transporter 1 (GlyT-1), and that they have a good selectivity to glycine transporter 2 (GlyT-2) inhibitors.

Schizophrenia is a progressive and devastating neurological disease characterized by episodic positive symptoms such as delusions, hallucinations, thought disorders and psychosis and persistent negative symptoms such as flattened affect, impaired attention and social withdrawal, and cognitive impairments (Lewis DA and Lieberman JA, *Neuron, 28:325-33, 2000*). For decades research has focused on the "dopaminergic hyperactivity" hypothesis which has led to therapeutic interventions involving blockade of the dopaminergic system (Vandenberg RJ and Aubrey KR., *Exp. Opin. Ther. Targets, 5(4): 507-518, 2001*; Nakazato A and Okuyama S, et al., *Exp. Opin. Ther. Patents, 10(1): 75-98, 2000*). This pharmacological approach poorly address negative and cognitive symptoms which are the best predictors of functional outcome (Sharma T., *Br.J. Psychiatry, 174(suppl. 28): 44-51, 1999).*

A complementary model of schizophrenia was proposed in the mid-1960' based upon the psychotomimetic action caused by the blockade of the glutamate system by compounds like phencyclidine (PCP) and related agents (ketamine) which are non-competitive NMDA receptor antagonists. Interestingly in healthy volunteers, PCP-induced psychotomimetic action incorporates positive and negative symptoms as well as cognitive dysfunction, thus closely resembling schizophrenia in patients (Javitt DC et al., *Biol. Psychiatry, 45: 668-679,* 1999). Furthermore transgenic mice expressing reduced levels of the NMDAR1 subunit displays behavioral abnormalities similar to those observed in pharmacologically induced models of schizophrenia, supporting a model in which reduced NMDA receptor activity results in schizophrenia-like behavior (Mohn AR et al., *Cell, 98: 427-236,* 1999*).*

Glutamate neurotransmission, in particular NMDA receptor activity, plays a critical role in synaptic plasticity, learning and memory, such as the NMDA receptors appears to serve as a graded switch for gating the threshold of synaptic plasticity and memory formation (Wiley, NY; Bliss TV and Collingridge GL, *Nature, 361: 31-39,* 1993). Transgenic mice overexpressing the NMDA NR2B subunit exhibit enhanced synaptic plasticity and superior ability in learning and memory (Tang JP et al., *Natur, 401- 63-69, 1999*).

Thus, if a glutamate deficit is implicate in the pathophysiology of schizophrenia, enhancing glutamate transmission, in particular via NMDA receptor activation, would be predicted to produce both anti-psychotic and cognitive enhancing effects.

The amino acid glycine is known to have at least two important functions in the CNS. It acts as an inhibitory amino acid, binding to strychnine sensitive glycine receptors, and it also influences excitatory activity, acting as an essential co-agonist with glutamate for N-methyl-D-aspartate (NMDA) receptor function. While glutamate is released in an activity-dependent manner from synaptic terminals, glycine is apparently present at a more constant level and seems to modulate/control the receptor for its response to glutamate.

One of the most effective ways to control synaptic concentrations of neurotransmitter is to influence their re-uptake at the synapses. Neurotransmitter transporters by removing neurotransmitters from the extracellular space, can control their extracellular lifetime and thereby modulate the magnitude of the synaptic transmission (Gainetdinov RR et al, *Trends in Pharm. Sci., 23(8): 367-373, 2002*).

Glycine transporters, which form part of the sodium and chloride family of neurotransmitter transporters, play an important role in the termination of post-synaptic glycinergic actions and maintenance of low extracellular glycine concentration by re-uptake of glycine into presynaptic nerve terminals and surrounding fine glial processes.

Two distinct glycine transporter genes have been cloned (GlyT-1 and GlyT-2) from mammalian brain, which give rise to two transporters with ~50 % amino acid sequence homology. GlyT-1 presents four isoforms arising from alternative splicing and alternative promoter usage (1a, 1b, 1c and 1d). Only two of these isoforms have been found in rodent brain (GlyT-1a and GlyT-1b). GlyT-2 also presents some degree of heterogeneity. Two GlyT-2 isoforms (2a and 2b) have been identified in rodent brains. GlyT-1 is known to be located in CNS and in peripheral tissues, whereas GlyT-2 is specific to the CNS. GlyT-1 has a predominantly glial distribution and is found not only in areas corresponding to strychnine sensitive glycine receptors but also outside these areas, where it has been postulated to be involved in modulation of NMDA receptor function (Lopez-Corcuera B et al., *Mol. Mem. Biol., 18: 13-20, 2001*). Thus, one strategy to enhance NMDA receptor activity is to elevate the glycine concentration in the local microenvironment of synaptic NMDA receptors by inhibition of GlyT-1 transporter (Bergereon R. et al., *Proc. Natl. Acad. Sci. USA, 95: 15730-15734,* 1998; Chen L. et al., *J. Neurophysiol., 89(2): 691-703,* 2003).

Glycine transporters inhibitors are suitable for the treatment of neurological and neuropsychiatric disorders. The majority of diseases states implicated are psychoses, schizophrenia (Armer RE and Miller DJ, *Exp. Opin. Ther. Patents, 11 (4): 563-572, 2001),* psychotic mood disorders such as severe major depressive disorder, mood disorders associated with psychotic disorders such as acute mania or depression, associated with

bipolar disorders and mood disorders, associated with schizophrenia, (Pralong ET et al., *Prog. Neurobiol., 67: 173-202, 2002*), autistic disorders (Carlsson ML, *J. Neural Trans,. 105: 525-535, 1998*), cognitive disorders such as dementias, including age related dementia and senile dementia of the Alzheimer type, memory disorders in a mammal, including a human, attention deficit disorders and pain (Armer RE and Miller DJ, *Exp. Opin. Ther. Patents, 11 (4): 563-572, 2001*).

Thus, increasing activation of NMDA receptors via GlyT-1 inhibition may lead to agents that treat psychosis, schizophrenia, dementia and other diseases in which cognitive processes are impaired, such as attention deficit disorders or Alzheimer's disease.

Objects of the present invention are the compounds of formula I per se, the use of compounds of formula I and their pharmaceutically acceptable salts for the manufacture of medicaments for the treatment of diseases related to activation of NMDA receptors via Glyt-1 inhibition, their manufacture, medicaments based on a compound in accordance with the invention and their production as well as the use of compounds of formula I in the control or prevention of illnesses such as psychoses, disfunction in memory and learning, schizophrenia, dementia and other diseases in which cognitive processes are impaired, such as attention deficit disorders or Alzheimer's disease.

1. Preparation of compounds of formula I following Procedure A

Compounds of formula I with $R^1 - R^4$ as defined above and A-A is $-(CH_2)_{2,3}-$ are prepared by reductive amination of 2-aryl or 2-heteroaryl-cyclohexanone or 2-aryl or 2-heteroaryl-cycloheptanone (3) and an accordingly substituted 1,3,8-triazaspiro[4.5]decan-4-one (2) using procedures established in the art, such as reacting the two components in presence of titanium(IV) tetraisopropoxide in an organic solvent, e.g. EtOH or THF, at ambient temperature to reflux temperature for 1 – 48 h, preferred 20 h, followed by reduction of the intermediate with a reductive agent, preferred a borohydride like $NaBH_3CN$, $NaBH(OAc)_3$ or $NaBH_4$, at ambient temperature to reflux temperature, preferred 20 °C to 50 °C.

Procedure A

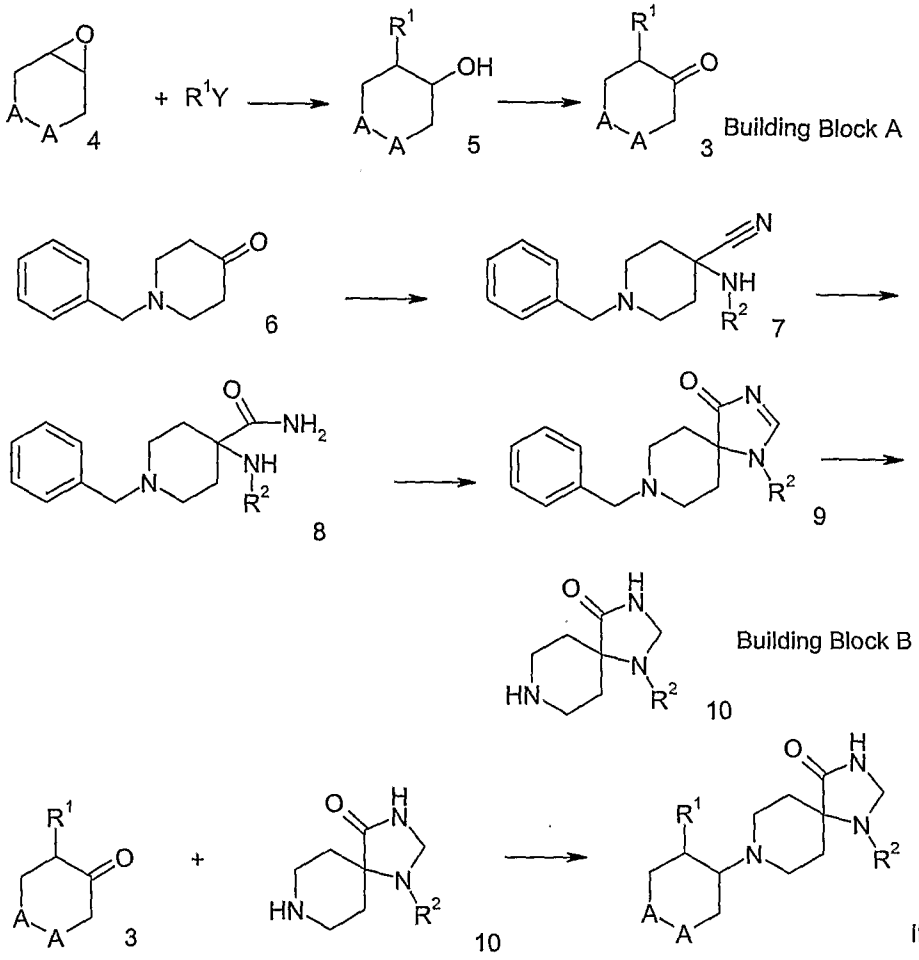

Scheme 1

The substituted 1,3,8-triazaspiro[4.5]decan-4-ones (2) with R^2, R^3 and R^4 as defined above are prepared from accordingly substituted 8-(3,5-bis-trifluoromethyl-benzoyl)-1,3,8-triaza-spiro[4.5]decan-4-ones (1) (described in WO0194346) by hydrolysis of the starting material with an inorganic base, e.g. NaOH or LiOH.

Procedure A1

Scheme 2

The new 2-aryl or 2-heteroaryl cyclohexanones or 2-aryl or 2-heteroaryl cycloheptanones (3) (Building Block A) are prepared in analogy to congeners already described in the literature. The first step, reaction of the cyclohexene oxide or cycloheptene oxide with chloro-, bromo- or iodo-magnesium or lithium aryl derivatives (R^1Y) provided the corresponding 2-aryl-cyclohexanols (5) *(Tetrahedron:Asymmetry 5, 223, 1994 and J.Am.Chem. Soc., 106, 3693, 1984)* which were oxidised with periodinane (Dess-Martin reagent) following a known procedure *(J. Org.Cem., 59, 7549, 1994).*

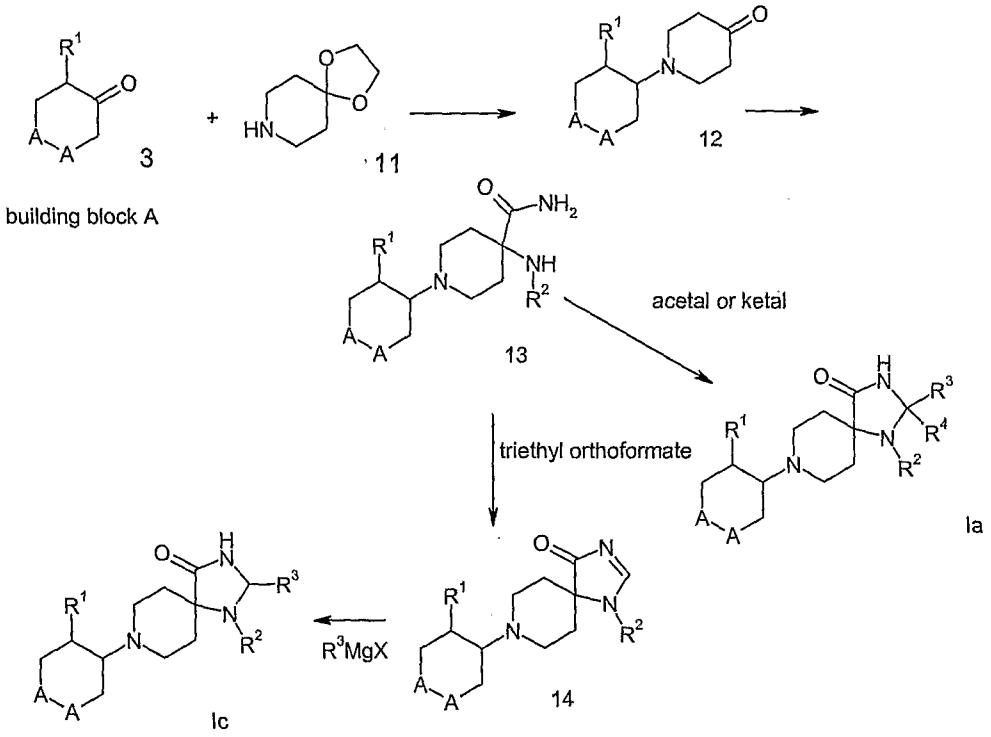

The new 1,3,8-triaza-spiro[4.5]decan-4-ones (10) (Building Block B) are prepared in analogy to procedures described in the literature for the synthesis of such compounds starting from N-protected piperidin-4-ones (6). The 1-benzyl-4-piperidone is first submitted to a Strecker type synthesis providing the 4-cyano-4-amino derivative (7), which is treated with 90 % sulfuric acid for 1 h to 40 h, preferred 2 h to 4 h at ambient temperature to provide the 4-amido-4-amino compound (8). This compound is then heated together with triethyl orthoformate in presence of acetic acid to reflux

temperature for 20 h to 72 h, preferred for 24 h to 48 h, or under microwave irradiation to 120 °C to 200 °C, preferred 150 °C to 200 °C for 10 min. to 30 min., preferred 15 min. to 20 min. The resulting 1-benzyl-spiro-imine (9) is then hydrogenated in presence of Pd on charcoal in a suitable solvent providing the de-protected and saturated 1,3,8-triaza-spiro[4.5]decan-4-ones (10).

Building blocks A and B are submitted to a reductive amination as described above for Procedure A.

2. Preparation of compounds of formula I following Procedure B

Scheme 3

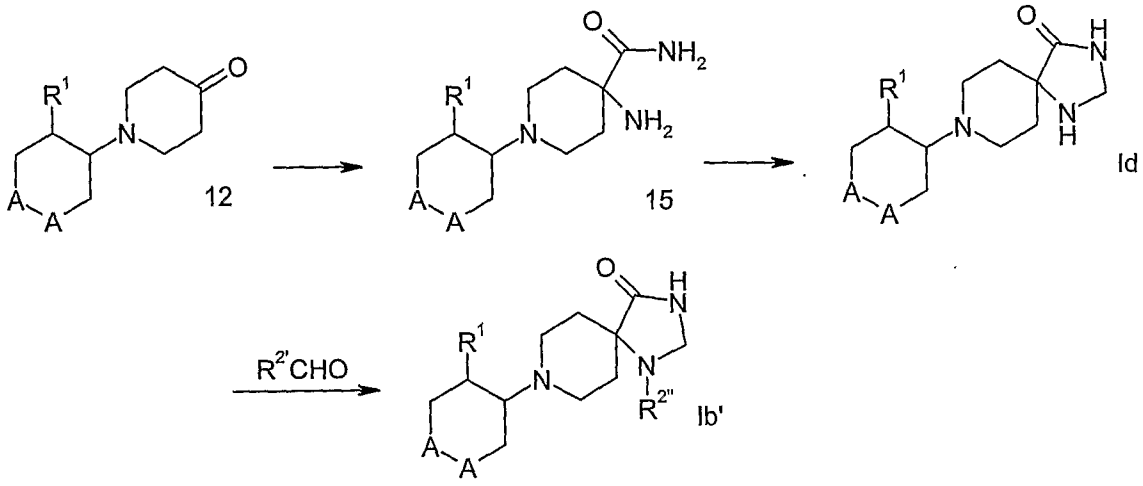

Piperidones (12) are synthesised in two steps from 2-aryl or 2-heteroaryl cyclohexanone or from 2-aryl or 2-heteroaryl cycloheptanone (3) and 1,4-dioxa-8-aza-spiro[4,5]decane (11). The reductive amination can be performed following the procedures already mentioned in Procedure A or via the corresponding enamines which are obtained by condensation of the starting materials under acidic conditions, e.g. with p-toluenesulfonic acid, in an azeotrope forming solvent like toluene at reflux temperature for 16 to 48 hours, preferred 24 hours, in an apparatus equipped with a Dean-Stark trap. The enamines are reduced following the procedures described in Procedure A. Hydrolysis of the ketal under acidic conditions, preferred is aqueous 6N HCl in methanol, at reflux temperature for 1 to 16 hours, preferred 2 to 4 hours, following textbook procedures provides piperidones (12). Following Procedure A1 for intermediate (8) in the synthesis

of building block B provides intermediate (13) in Procedure B. Reaction of (13) with triethyl orthoformate provides 1,3,8-triaza-spiro[4.5]dec-2-en-4-one (14) which after reaction with a Grignard reagent R^3MgX yields final product Ic.

Compounds Ia are synthesized by acid promoted condensation of intermediate (13) with acetals or ketals. The reaction is usually conducted in toluene in which the starting materials are dissolved. To control the exothermic reaction the acid, usually p-toluenesulfonic acid, is added portionwise.

Treatment of the latter with an alkyl-magnesium halide of formula R^6MgX for R^6 = lower alkyl in an ether as solvent, preferred is THF, at 0 °C to reflux temperature leads to the final product Ih.

The acid addition salts of the basic compounds of formula I may be converted to the corresponding free bases by treatment with at least a stoichiometric equivalent of a suitable base such as sodium or potassium hydroxide, potassium carbonate, sodium bicarbonate, ammonia, and the like.

The compounds of formula I and their pharmaceutically usable addition salts possess valuable pharmacological properties. Specifically, it has been found that the compounds of the present invention are good inhibitors of the glycine transporter 1 (GlyT-1).

The compounds were investigated in accordance with the test given hereinafter.

Uptake buffer (UB): 150 mM NaCl, 10 mM Hepes-Tris, pH 7.4, 1 mM $CaCl_2$, 2.5 mM KCl, 2.5 mM $MgSO_4$, 10 mM (+) D-glucose.
Flp-in™-CHO (Invitrogen Cat n° R758-07)cells stably transfected with mGlyT-1b cDNA.

Glycine uptake inhibition assay (mGlyT-1b)

On day 1 mammalian cells, (Flp-in™-CHO), transfected with mGlyT-1b cDNA , were plated at the density of 40,000 cells/well in complete F-12 medium, without hygromycin in 96-well culture plates. On day 2, the medium was aspirated and the cells were washed twice with uptake buffer (UB). The cells were then incubated for 20 min at 22°C with either (i) no potential competitor, (ii) 10 mM non-radioactive glycine , (iii) a concentration of a potential inhibitor. A range of concentrations of the potential inhibitor was used to generate data for calculating the concentration of inhibitor resulting in 50 % of the effect (e.g. IC_{50}, the concentration of the competitor inhibiting glycine uptake of 50 %). A solution was then immediately added containing [^{3}H]-glycine 60 nM (11-16 Ci/mmol) and 25 µM non-radioactive glycine. The plates were incubated with gentle shaking and the reaction was stopped by aspiration of the mixture and washing (three times) with ice-cold UB. The cells were lysed with scintillation liquid, shaken 3 hours and the radioactivity in the cells was counted using a scintillation counter.

As shown in the table below, preferred compounds have an $IC_{50} < 0.10$ µM at GlyT-1.

The compounds of formula I and the pharmaceutically acceptable salts of the compounds of formula I can be used as medicaments, e.g. in the form of pharmaceutical preparations. The pharmaceutical preparations can be administered orally, e.g. in the form of tablets, coated tablets, dragées, hard and soft gelatine capsules, solutions, emulsions or suspensions. The administration can, however, also be effected rectally, e.g. in the form of suppositories, parenterally, e.g. in the form of injection solutions.

The compounds of formula I can be processed with pharmaceutically inert, inorganic or organic carriers for the production of pharmaceutical preparations. Lactose, corn starch or derivatives thereof, talc, stearic acids or its salts and the like can be used,

for example, as such carriers for tablets, coated tablets, dragées and hard gelatine capsules. Suitable carriers for soft gelatine capsules are, for example, vegetable oils, waxes, fats, semi-solid and liquid polyols and the like. Depending on the nature of the active substance no carriers are however usually required in the case of soft gelatine capsules. Suitable carriers for the production of solutions and syrups are, for example, water, polyols, glycerol, vegetable oil and the like. Suitable carriers for suppositories are, for example, natural or hardened oils, waxes, fats, semi-liquid or liquid polyols and the like.

The pharmaceutical preparations can, moreover, contain preservatives, solubilizers, stabilizers, wetting agents, emulsifiers, sweeteners, colorants, flavorants, salts for varying the osmotic pressure, buffers, masking agents or antioxidants. They can also contain still other therapeutically valuable substances.

Medicaments containing a compound of formula I or a pharmaceutically acceptable salt thereof and a therapeutically inert carrier are also an object of the present invention, as is a process for their production, which comprises bringing one or more compounds of formula I and/or pharmaceutically acceptable acid addition salts and, if desired, one or more other therapeutically valuable substances into a galenical administration form together with one or more therapeutically inert carriers.

The most preferred indications in accordance with the present invention are those, which include disorders of the central nervous system, for example the treatment or prevention of schizophrenia, cognitive impairment and Alzheimer's disease.

The dosage can vary within wide limits and will, of course, have to be adjusted to the individual requirements in each particular case. In the case of oral administration the dosage for adults can vary from about 0.01 mg to about 1000 mg per day of a compound of general formula I or of the corresponding amount of a pharmaceutically acceptable salt thereof. The daily dosage may be administered as single dose or in divided doses and, in addition, the upper limit can also be exceeded when this is found to be indicated.

The following examples illustrate the present invention without limiting it. All temperatures are given in degree Celsius.

Procedure A

Example 1

(rac,cis)-1-Phenyl-8-(2-phenyl-cyclohexyl)-1,3,8-triaza-spiro[4.5]decan-4-one

To a solution of 10.0 g (57.4 mmol) rac-2-phenylcyclohexanone in 200 ml THF were added 13.27 g (57.4 mmol) 1-phenyl-1,3,8-triazaspiro[4.5]decan-4-one and 16.3 g (17.0 ml, 57.4 mmol) titanium(IV) tetraisopropoxide. The mixture was stirred under Argon at ambient temperature for 20 h. Then at 40 – 50 ° C/15 mbar the volatiles were distilled off and the residue dissolved in 100 ml EtOH and 20 ml THF. To this stirred solution were added under Argon 2.41 g (38.5 mmol) $NaBH_3CN$ and the mixture stirred at ambient temperature for 20 h. To the reaction mixture were added 25 ml water and the resulting slurry stirred for 30 min. The slurry was filtered through a Dicalite pad which was carefully washed with EtOH. The combined filtrates were evaporated and the residue dissolved in EtOH and a small volume of $CHCl_3$ and a sat. HCl/EtOH solution added. After stirring at ambient temperature for 2 h, the precipitate was collected and the crystals washed with methanol. This solid, (rac,cis)-1-phenyl-8-(2-phenyl-cyclohexyl)-1,3,8-triaza-spiro[4.5]decan-4-one hydrochloride, was distributed between 0.1N NaOH and ethyl acetate, the organic phase washed with water to neutral pH, dried over Na_2SO_4 and evaporated. The resulting slightly yellow residue was re-crystallised from Et_2O: 5.97 g (rac,cis)-1-phenyl-8-(2-phenyl-cyclohexyl)-1,3,8-triaza-spiro[4.5]decan-4-one as colourless crystals: m.p. 205–208° C, MS (ISP): 390.4 MH^+.
