The present invention relates to novel amide derivatives of 7-amino-3-phenyl dihydropyrimido[4,5-d]pyrimidinones, to a process for their manufacture, medicaments containing them and their manufacture as well as the use of these compounds as pharmaceutically active agents.

Some substituted bicyclic nitrogen heterocycles are known in the art for their protein kinase, as well as their tyrosine kinase inhibitory activity. WO 01/29042 and WO 01/29041 disclose alkylamino-substituted dihydropyrimido[4,5-d]pyrimidinone derivatives with p38 inhibitory activity. WO 99/61444 describes dihydropyrimido[4,5-d]pyrimidinones, substituted with aryl and heteroarylamines, sulfides, sulfoxides and sulfones as inhibitors for cyclin-dependent kinases (cdks) and tyrosine kinases. Aryl and heteroarylamine substituted dihydropyrimido[4,5-d]pyrimidinones are also described in WO 00/24744 as inhibitors of T-cell tyrosine kinase $p56^{lck}$. Further dihydropyrimido[4,5-d]pyrimidinones with tyrosine kinase inhibitory activity are described in WO 04/18472, WO 04/41821, WO 04/41822, WO 04/41823, and WO 04/11465.

(c) if desired converting said compound of the general formula I into a pharmaceutically acceptable salt.

The compounds of formula I, or a pharmaceutically acceptable salt thereof, which are subject of the present invention may be prepared by any process known to be applicable to the preparation of chemically-related compounds. Such processes, when used to prepare a 7-amino-3-phenyl dihydropyrimido[4,5-d]pyrimidinone derivative of the formula I, or a pharmaceutically-acceptable salt thereof, are illustrated by the following representative schemes and examples in which, unless otherwise stated, R^1, R^2, and R^3 have the significance defined hereinbefore. Necessary starting materials may be obtained by standard procedures of organic chemistry. The preparation of such starting materials is described within the accompanying examples. Alternatively necessary starting materials are obtainable

by analogous procedures to those illustrated which are within the ordinary skill of an organic chemist.

The compounds of formula I can be prepared from 4-chloro-2-methylsulfanyl-pyrimidine-5-carboxylic acid ethyl ester, which is known from WO 04/41823, according to schemes 1, 2, and 3, wherein R^1, R^2, and R^3 have the significance given above.

Scheme 1

Step 1:

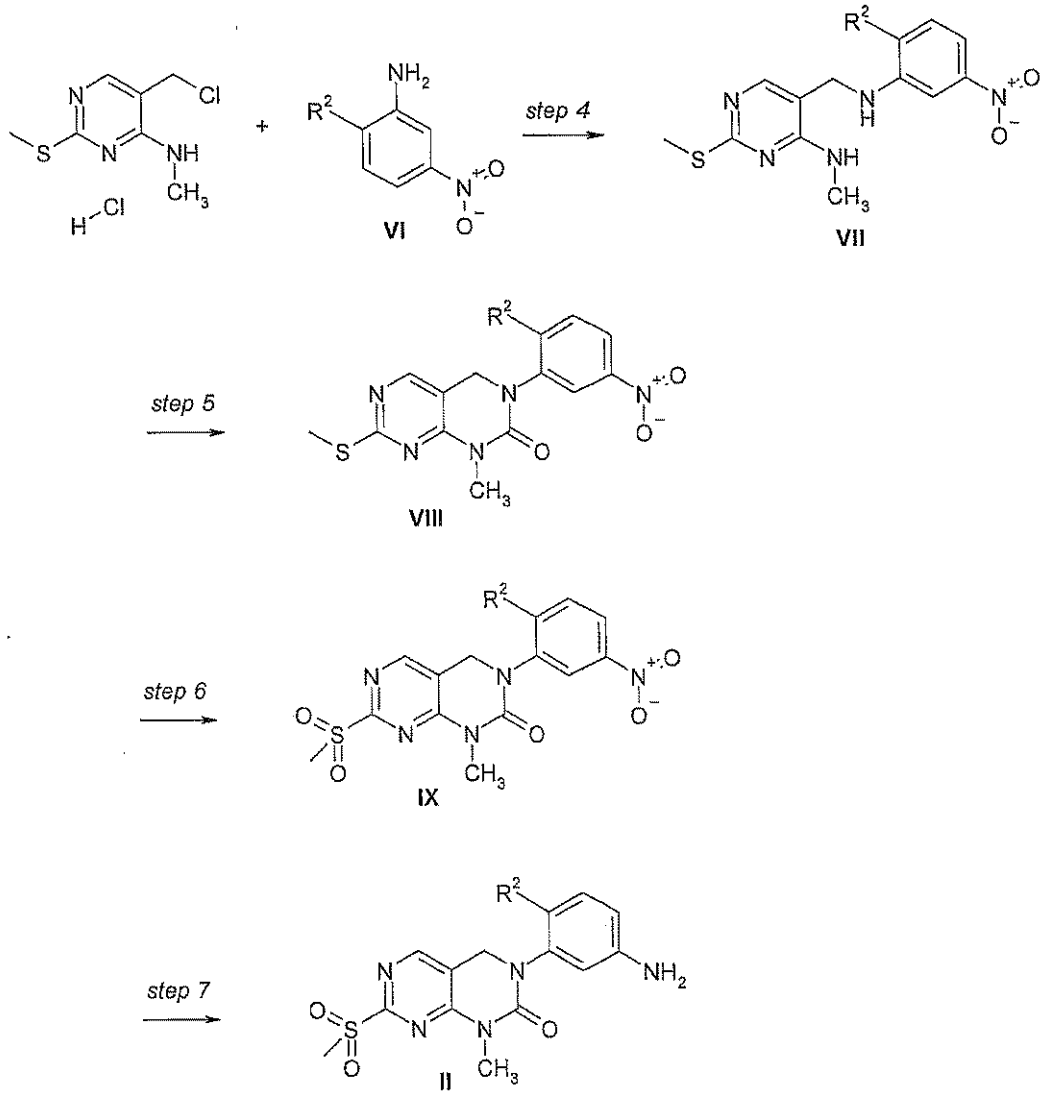

4-Methylamino-2-methylsulfanylpyrimidine-5-carboxylic acid ethyl ester was prepared from 4-chloro-2-methylsulfanyl-pyrimidine-5-carboxylic acid ethyl ester and methylamine in tetrahydrofuran (THF) under basic conditions with triethylamine at temperatures between 5 °C and room temperature (RT).

Step 2:

(4-Methylamino-2-methylsulfanyl-pyrimidin-5-yl)-methanol was prepared by reduction of 4-methylamino-2-methylsulfanylpyrimidine-5-carboxylic acid ethyl ester with lithium aluminiumhydride in tetrahydrofuran (THF) at temperatures ranging from 5 °C to room temperature (RT).

Step 3:

(4-Methylamino-2-methylsulfanyl-pyrimidin-5-yl)-methanol was converted to (5-chloromethyl-2-methylsulfanyl-pyrimidin-4-yl)-methyl-amine with thionyl chloride in 1,1,1-trichloroethane at room temperature.

Scheme 2

Step 4:

(5-Chloromethyl-2-methylsulfanyl-pyrimidin-4-yl)-methyl-amine was reacted with compounds of the formula VI by the addition of sodium iodide and N-

ethyldiisopropylamine in acetonitrile or in solvents of similar polarity at a temperature range between -20 °C and 180 °C to give compounds of the formula VII.

Step 5:

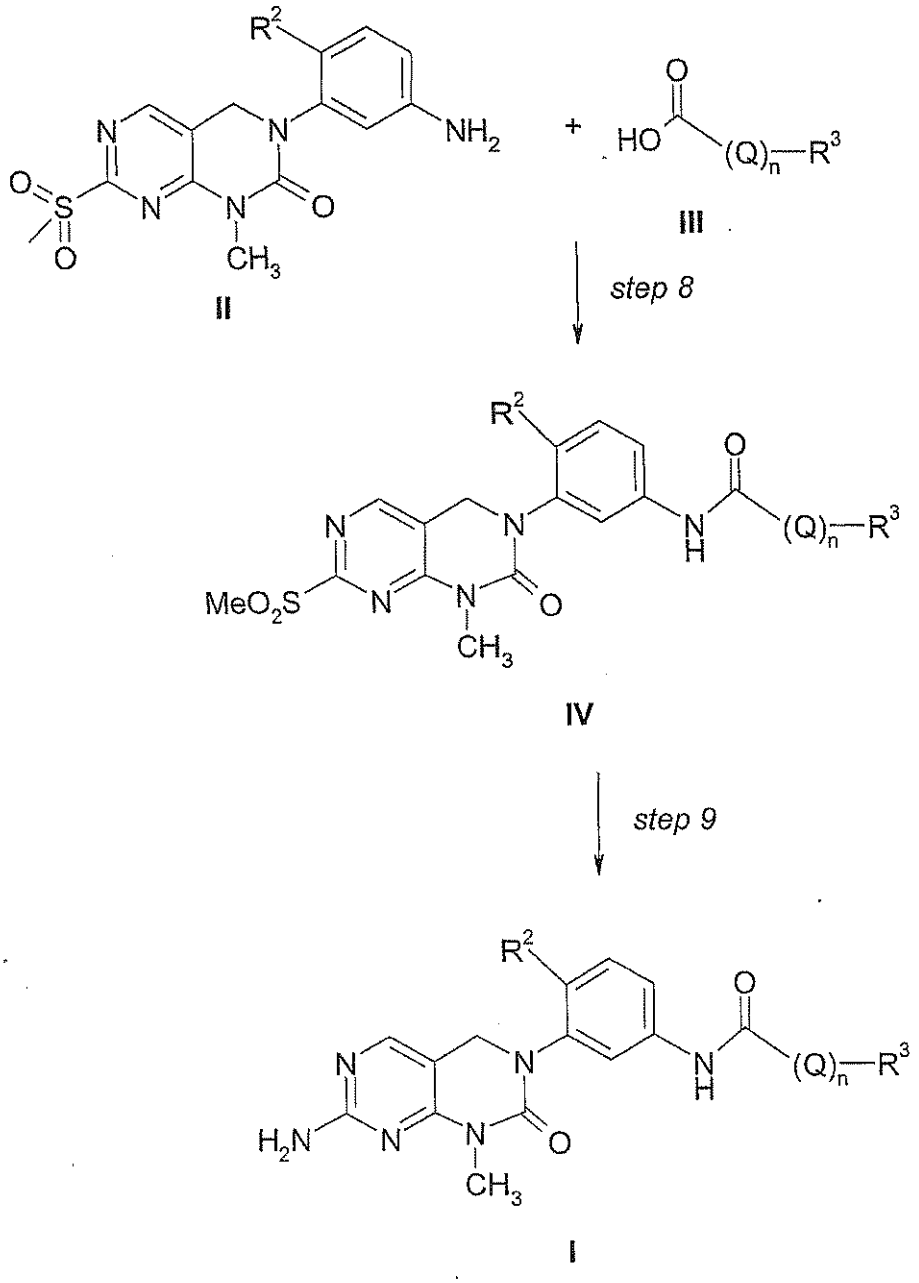

Compounds of formula VIII can be prepared from compounds of formula VII by treatment with 1,1'-carbonyldiimidazole and potassium carbonate (K_2CO_3) at a temperature range from 0 °C to 180 °C in acetonitrile or in solvents of similar polarity such as dimethyl formamide (DMF) or tetrahydrofuran (THF). Alternatively, e.g. sodium hydride in dimethyl formamide/tetrahydrofuran can be used.

Step 6:

A methylthio group can be converted into the suitable leaving group by oxidation to the sulfoxide. Compounds of formula VIII are converted to compounds of formula IX with 3-chloroperoxybenzoic acid (mCPBA) as oxidizing reagent in an inert solvent such as dichloromethane (CH_2Cl_2), THF or NMP at a temperature range from 0°C to 150 °C to give compounds of formula (IX).

Step 7:

The compounds of formula IX are reduced to compounds of formula II by hydrogenation using deactivated Pd(CaCO3)/C or other Pd catalysts. The reduction takes place at a temperature range between 0 °C and 150 °C in inert solvents such as THF, CH_2Cl_2, or NMP .

Scheme 3

Step 8:

Compounds of formula II are coupled to carboxylic acids of formula III to give the amides of formula IV. Common reagents for the activation of carboxylic acid were used such as e.g. 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride

(EDCI), N,N′-dicyclohexylcarbodiimide (DCC), 1-hydroxybenzotriazole (HOBT), N,N′-carbonyldiimidazole (CDI), and 4-(4,6-dimethoxy-[1,3,5]triazin-2yl)-4-methyl-morpholin-4-ium chloride (DMTMM) in inert solvents such as THF, CH_2Cl_2, or NMP or in polar solvents such methanol (MeOH) or even water. Sometimes dimethylaminopyridine (DMAP) was added as a catalyst. Another method of activation is the preparation of the corresponding acid chlorides. The condensation reaction may be carried out under basic conditions. e.g. in the presence of triethylamine, N,N-diisopropylethylamine (Hünig base). Some acids bearing functional groups which were not stable under the reaction conditions were protected with standard protection groups such as t-butoxycarbonyl (Boc) or benzyloxycarbonyl .

Step 9:

The compounds of formula IV are transformed into compounds of formula I by treatment with ammonia. One method consists of autoclaving a solution of compound IV and liquid ammonia and stirring at a temperature range of -20 – 100 °C until the transformation is complete. An alternative method comprises of treatment of a solution of compound IV with an aqueous solution of ammonia under a continuous flow of gaseous ammonia.

Certain side chains in R^3 may require protection during the reaction sequences. Here standard protection and deprotection procedures being well known in the art may be applied. For instance, primary and secondary amines can be applied in t-butoxycarbonyl (Boc) or benzyloxycarbonyl protected form and the protecting group can be removed as a last reaction step by treatment with an acid like HCl or TFA.

The compounds of the general formula I can contain one or several chiral centers and can then be present in a racemic or in an optically active form. The racemates can be separated according to known methods into the enantiomers. For instance, diastereomeric salts which can be separated by crystallization are formed from the racemic mixtures by reaction with an optically active acid such as e.g. D- or L-tartaric acid, mandelic acid, malic acid, lactic acid or camphorsulfonic acid. Alternatively separation of the enantiomers can also be achieved by using chromatography on chiral HPLC-phases which are commercially available.

The compounds according to the present invention may exist in the form of their pharmaceutically acceptable salts. The term "pharmaceutically acceptable salt" refers to conventional acid-addition salts or base-addition salts that retain the biological effectiveness and properties of the compounds of formula I and are formed from suitable non-toxic organic or inorganic acids or organic or inorganic bases. Acid-addition salts include for example those derived from inorganic acids such as hydrochloric acid, hydrobromic acid, hydroiodic acid, sulfuric acid, sulfamic acid, phosphoric acid and nitric acid, and those derived from organic acids such as p-toluenesulfonic acid, salicylic acid, methanesulfonic acid, oxalic acid, succinic acid, citric acid, malic acid, lactic acid, fumaric acid, and the like. Base-addition salts include those derived from ammonium, potassium, sodium and, quaternary ammonium hydroxides, such as for example, tetramethylammonium hydroxide. The chemical modification of a pharmaceutical compound into a salt is a technique well known to pharmaceutical chemists in order to obtain improved physical and chemical stability, hygroscopicity, flowability and solubility of compounds. It is for example described in Stahl, P. H., and Wermuth, G., (editors), Handbook of Pharmaceutical Salts, Verlag Helvetica Chimica Acta (VHCA), Zürich, (2002) or Bastin, R.J., et al., Organic Proc. Res. Dev. 4 (2000) 427-435.

The compounds according to this invention and their pharmaceutically acceptable salts can be used as medicaments, e.g. in the form of pharmaceutical preparations. The pharmaceutical preparations can be administered orally, e.g. in the form of tablets, coated tablets, dragées, hard and soft gelatine capsules, solutions, emulsions or suspensions. The administration can, however, also be effected rectally, e.g. in the form of suppositories, or parenterally, e.g. in the form of injection solutions.

The above-mentioned pharmaceutical preparations can be obtained by processing the compounds according to this invention with pharmaceutically inert, inorganic or organic carriers. Lactose, corn starch or derivatives thereof, talc, stearic acids or its salts and the like can be used, for example, as such carriers for tablets, coated tablets, dragées and hard gelatine capsules. Suitable carriers for soft gelatine capsules are, for example, vegetable oils, waxes, fats, semi-solid and liquid polyols and the like. Depending on the nature of the active substance no carriers are, however, usually required in the case of soft gelatine capsules. Suitable carriers for the production of solutions and syrups are, for example, water, polyols, glycerol,

vegetable oil and the like. Suitable carriers for suppositories are, for example, natural or hardened oils, waxes, fats, semi-liquid or liquid polyols and the like.

The pharmaceutical preparations can, moreover, contain preservatives, solubilizers, stabilizers, wetting agents, emulsifiers, sweeteners, colorants, flavorants, salts for varying the osmotic pressure, buffers, masking agents or antioxidants. They can also contain still other therapeutically valuable substances.

A pharmaceutical preparation is obtained by using the following procedure:

1. Weigh 4.0 g glass beads in custom made tube GL 25, 4 cm (the beads fill half of the tube).
2. Add 50 mg compound, disperse with spatulum and vortex.
3. Add 2 ml gelatin solution (weight beads: gelatin solution = 2:1) and vortex.
4. Cap and wrap in aluminium foil for light protection.
5. Prepare a counter balance for the mill.
6. Mill for 4 hours, 20/s in a Retsch mill (for some substances up to 24 hours at 30/s).
7. Extract suspension from beads with two layers of filter (100 µm) on a filter holder, coupled to a recipient vial by centrifugation at 400 g for 2 min.
8. Move extract to measuring cylinder.
9. Repeat washing with small volumes(here 1 ml steps) until final volume is reached or extract is clear.
10. Fill up to final volume with gelatin and homogenise.

The above described preparation procedure yields micro-suspensions of the compounds of formula I with particle sizes between 1 and 10 µm. The suspensions are suitable for oral applications and can be used in the in vivo pharmacokinetic testings.

whereby both peptides were synthesized by an optimized solid phase peptide synthesis protocol (Merrifield, Fed. Proc. Fed. Amer. Soc. Exp. Biol. 21 (1962) 412) on a Zinsser SMP350 peptide synthesizer. Shortly, the peptide was assembled on 160 mg (22.8 µmol scale) of a Rink-Linker modified polystyrene solid phase by repeatedly

conjugating an twenty fold excess of amino acids each protected by temporary piperidine labile Fmoc- and permanent acid labile tert-Bu-, BOC- and O-tert-Bu-groups depending on the side chain function. The substrate sequence AEEEIYGEFEAKKKK was N-terminal additionally mounted with the spacer amino acids Aminocaprylic acid and Glycin. After cleavage of the N-terminal temporary protecting group the still attached and protected peptide was labeled with a 1.5 fold amount of LightCycler-Red 640-N-hydroxy succinimide ester (purchased from Roche Diagnostics GmbH) and triethylamine. After 3 hrs. the resin was washed with Dimethylformamide and Isopropanol until the eluates of the blue resin got colourless. The fully protected and labeled peptide was removed from the solid phase and released from the permanent protecting groups by treatment with a mixture of 80% trifluoroacetic acid, 10% Ethanedithiol, 5% Thioanisol and 5% Water. The substrate was finally isolated by a preparative reverse phase HPLC purification. The purification yielded 12.2 mg RP-HPLC single peak pure blue material (lyophilisate). The identity was proven by MALDI mass spectroscopy [2720.0].
