BANDED MAGNETIC RECORDING DISK WITH EQUALLY-ANGULARLY-SPACED SERVO SECTORS

FIELD OF THE INVENTION

This invention relates to methods and means for providing and sampling servo sections on a movable recording medium, and more particularly relates to such a method and means wherein the rate at which the servo sectors are sampled on a disk file or servo sections are sampled on a tape drive is independent of the data architecture used.

BACKGROUND OF THE INVENTION

The above-referenced related application discloses a method and means for increasing the servo sector sampling rate in a disk formatted in a fixed block architecture (FBA), such increase being effected with a minimal increase in the overhead (non-data) regions. The disk has the prior art conventional servo sectors which contain all servo and associated overhead information. However, micro servo sectors are inserted in the data fields between the conventional servo sectors to provide short bursts of servo information. These micro servo sectors contain a small portion of the overhead information, only sufficient to provide position information and to control the temporary interruption and restoration of the write current and the data stream and clock input to a data encoder/decoder. Because the servo bursts are short, no resynchronization of the VCO is necessary after each burst. These micro sector bursts are used only during settling (since they contain only position error signal data) and also preferably during seek (if an abbreviated Gray code is used); and the conventional sector servo bursts are used during read and write track following. This technique desirably provides high sample rates with minimal overhead in disk files using a sectored servo system, such as used in low end disk files with FBA format.

Several techniques, now becoming increasingly popular to increase the arcal density in sectored disk files, are constant linear density (CLD) recording and banded recording. In CLD recording, the data rate for a given track depends upon its radius. Banded recording is somewhat similar, except that the data rate is constant within a given band of radii, but varies from band to band to minimize the range of linear densities. It follows, then, that if implemented in sectored servo, the number of sectors and hence of servo samples would increase progressively from the innermost to the outermost bands, and thus require the servo system to adjust to the differing sample rates. Also, seeks across bands and settles at band edges would require constant updating of the sample rate, and timing of the servo samples would vary.

There is a need for a recording technique, transparent to the user, useful for both non-sectored and sectored disk and tape formats, wherein servo sample rate is constant and is independent of the data architecture used and limited only by the total area of the disk devoted to servo information.

SUMMARY OF THE INVENTION

Toward this end, and according to the invention, a method and means is described wherein servo sectors written on a disk (or servo sections written on a tape) are equally spaced on a given track and read during seek, settle and track following operations. An algorithm is used to determine the allowable time separation between servo sectors (or sections) on a track and lengths of associated data sections, such as data sectors or variable length records, that may be accommodated on the disk or tape in such manner that each of the servo sectors (or sections) equally spaced on a given track is located within a data field of a data sector or within an identification region or immediately after an address indicating mark (such as address mark or index mark). The rate at which the servo sector (or section) is sampled is constant and independent of the number and lengths of the data sections. As a result of this independent relationship, this technique is suitable for CLD recording, to banded disks using sectored servo as in conventional FBA, and also even to non-sectored architectures, such as count-key-data (CKD), wherein the data is written in records of variable length, and to tape drives formatted in FBA or CKD.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a diagram, not to scale, showing the regions and fields of a typical prior art data sector for a track on a disk file formatted for conventional sectored FBA;

FIG. 2 is a diagram, also not to scale, of a servo sector according to the invention;

FIG. 3 is a diagram, also not to scale, of a data sector into which at selectable locations the servo sector may be inserted;

FIG. 4 is a diagram of a portion of a disk formatted in banded FBA depicting the constant sampling rate for all bands, the varied numbers of data sectors per band, and the servo sector locations in the respective bands; and

FIG. 5 is a block diagram showing the circuitry for implementing the invention.

DESCRIPTION OF PREFERRED EMBODIMENTS

I. INTRODUCTION - DESCRIPTION OF PRIOR ART SERVO SECTOR

As illustrated in FIG. 1, a typical prior art data sector 9 for a track on a FBA formatted disk comprises a servo region 10, an identification (ID) region 11, and a data

region 12. Write-read and speed field 15 allows time for the drive electronics to switch from write to read. Address mark (AM) field 16 is an asynchronous, absolute timing reference that identifies the beginning of the servo sector and provides the basis for locating the other fields. Position error signal (PES) field 17 contains the information needed to determine the track position of the recording head.

In ID region 11, read-write and speed field 18 allows the time needed to insure that PES field 17 is not overwritten and that sufficient time is provided for the write current to rise to its full value. VCO synchronization (VCO sync) field 19 is required to give the variable frequency read clock sufficient time to phase lock to the upcoming ID and CRC field 22. Encoder/decoder (ENDEC) flush field 20 indicates the number of bits the read channel decoder must receive in order to put it into a known state called ENDEC flush. Sync byte 21 indicates the sync byte needed to align the read bytes on current byte boundaries. ID and CRC field 22 includes as the ID portion a sector identifier and bad sector flag and as the CRC portion a cyclic redundancy check for errors in the reading of the ID.

In data region 12, fields 23-26 correspond to the ID fields 18-21, respectively. However, the function of sync byte field 26 is to tell the controller when the VCO synchronisation and ENDEC flush end and the read data, which is contained in field 27, begins. Data and ECC field 27 stores the user data together with the error correction code. Each data region in a conventional sector servo system is completely independent of data regions in the other data sectors.

For a more detailed description of the regions 10-12 and fields 15-27, the reader is referred to the referenced related application.

II. DESCRIPTION OF THE INVENTION SECTOR SERVO SYSTEM FOR BANDED RECORDING ON DISK

As illustrated in FIG. 2, servo sector 30, in accordance with the invention, differs significantly from the conventional sector 9. Sector 30 comprises a read-write field 31 having a code constraint (CC) portion 32 and a speed gap 33 which together provide the write-recovery function of field 15 of FIG. 1. The code constraint 32 consists of bits to prevent the decaying write current from writing a transition too close to the last data transition. Gap 33, which is to account for timing slop caused by variations in spindle speed of the disk drive motor, is inserted between field 31 and a servo start mark 34.

Mark 34 is at the leading end of the position error signal (PES) field 35 and marks the start of servo sampling. Between the end of PES field 35 and an optional VCO sync field 37 is a gap 36, again to account for variations in spindle speed. Following field 37 (or gap 36 if 37 is not used) is a field 38 containing a coding constraint and sync bits which,

for example, for a (2,7) code would be 00. Each of the fields 32,37,38 are completely written during a write operation; fields 31 and 36 are partially written during a write operation; and fields 33 and 35 are written only during a servo write operation.

It will thus be seen that each servo sector 30 consists solely of bits in PES field 35 containing position information and to each side thereof bits in fields for controlling the interruption and restoration of the writing and reading of data.

FIG. 3 illustrates the various regions or fields on a typical track 39 of a data sector M that may be used to implement the invention. The servo sector 30 is not included because, in accordance with the invention, it may be inserted anywhere within any of the locations indicated by the vertical arrows in FIG. 3.

As illustrated, each track 39 preferably contains the following fields: write-read recovery and AGC field 15'; pad fields 42,43, which compensate for timing slop; and fields 16', 18', 19', 22', 23', 24' and 27' which, with 15', are essentially similar to the corresponding unprimed fields in conventional sector servo 9 of FIG. 1.

Servo sectors 30 are written at the factory and are inserted either anywhere within the data field 27' or at certain other prescribed positions in each data sector M, such as the ID/CRC field 22', or ECC portion of field 27'. However, fields 22' and said ECC portion of field 27' are so small compared with the length of the data portion of field 27' that only a small gain in number of permissible sample positions would be achieved. As a practical matter, therefore, the servo sectors 30 preferably should be inserted anywhere in the data portion of field 27' or else immediately following AM 16'.

The servo sectors 30 should not be inserted in the sync fields 19' or 24' because the VCO is then attempting a phase or frequency lock, resulting in an unpredictable drift over a servo sample. Nor should servo sectors 30 be inserted in fields 15', 18' or 23' which are required for channel recovery or in pad fields 42, 43 used to accommodate timing slop.

It will be apparent that, if the servo samples occur at the AM 16', then CC field 32, W-R field 31 and gap field 33 are not required; and since pad field 42 would then follow the servo sample, VCO field 37 and CCSB field 38 are not required either. Although eliminating these fields by starting the servo samples at AM 16' desirably lowers the overhead, it probably is not sufficient enough to offset the advantage of having all the servo sectors be of identical length. In banded recording, especially, all servo sectors should be identical so that the servo system will operate independently of the banding.

FIG. 4 depicts a disk 50 formatted in FBA as banded sectors. According to an important feature of the invention, servo sectors 30 in each respective band A-D are written at equally circumferentially spaced intervals and are sampled (i.e., read) during seek, settle and track following operations. An allowable number of servo sectors per revolution and

the lengths of associated data regions 51 on disk 50 is calculated such that each of the equally spaced servo sectors 30 on a given track is located anywhere within either a data field 27' of a data region 51 or an identification region 22' or immediately after an index mark 52 or address mark 16' in a data sector M. As shown in FIGS. 3 and 4, each data sector M extends from the leading end of each "other" fields (which are the overhead fields) to the end of the adjacent data region 51.

According to an important feature of the invention, it is not necessary for each servo sector 30 to start at the AM 16' or index mark 52 for every data sector M or that the positions of the servo sectors be the same for every data sector. However, formatting will be simplified, if as illustrated in FIG. 4 the first servo sector in each band starts at the common radial index 52 and each succeeding servo sector in such band is initiated at successive locations in equally spaced time increments from said index. Thus, in disk 50 the data in each concentric band A-D is clocked at the same data rate but the data rates and number of data sectors M vary from band to band.

Not all combinations of servo sample rates and numbers of data sectors M per band are permissible. Permissible combinations are those where the ratio between the number of servo samples N per revolution and the number of data sectors M in a particular band A, B, C or D reduces to a ratio of small integers. For example, assume there are 60 servo samples N per revolution; that bands A, B, C and D have 30, 36, 40 and 50 data sectors M per band, respectively; and that all servo samples are initiated at index 52. As noted in FIG. 4, the ratios of servo samples N to data sectors M in each band are 2:1, 5:3, 3:2 and 6:5 starting from innermost band A. Note that in each case the servo samples line up either at the AM position 16' or within the data regions 51 for all sectors in all bands.

Relatively prime ratios of servo samples N to data sectors M, such as 60/31, are not desirable since they are likely to violate the placement constraints. The AM 16' position tends to fall near the middle of the gap between data files 27'; hence, the number of allowed combinations would be quite high. If the track does not have VCO or AGC sync fields, there are few servo placement restrictions because only the AM and gap fields need be avoided; and in such case nearly any ratio of servo sample N to data sectors M should be permissible, except the larger integer in either the numerator or denominator of said ratio preferably does not exceed twice the reciprocal of those portions of each track not devoted to data fields or identification fields of the data sectors.

The manner in which permissible combinations of servo samples and data sectors is computed is described in the Appendix attached hereto.

III. IMPLEMENTATION OF THE INVENTION

The servo system is initialized by locating a servo sector 30 at index mark 52 (FIG. 4). As illustrated in FIG. 5, clock generator 61 generates servo cycles which are counted by counter 62. When counter 62 reaches a preset terminal count corresponding to the number of servo clock cycles between each servo sector 3, it sends an enable signal to a start mark detector 63. Detector 63 then looks for the start mark 34 of a servo sector 30. When start mark 34 is located, detector 63 generates a start found signal, which is sent to a servo controller 64 and to counter 62. Counter 62 is reset by the start found signal and resumes counting. Servo controller 6 4 then reads the PES field 35 and other servo information such as a track ID Gray code, based upon the known timing offsets from start mark 34. Servo controller 64 then operates in the same manner as a typical prior art servo controller using the PES to control an actuator (not shown).

In the preceding description, it has been assumed that spindle speed control of the disk drive motor is sufficiently precise to permit completely open-loop operation; i.e. the open-loop counting cycle is repeated for each servo sector 30 and all the servo samples line up at common index 52 at the end of each revolution of the disk. If speed control timing slop is unacceptable, however, it can be reduced by placing a sync bit into PES field 35 to reset a sample timer and thereby update the timer at every sample time.

Data for read and write operations is processed in the same manner as in the prior art, with switches 76-79 closed and switch 80 positioned as shown, until a servo sector 30 is encountered. Servo sector locations are known and stored in a servo location register 74. Prior knowledge of these servo locations allows data timing and control circuitry 71 to make the servo sector transparent to the data channel. Circuitry 71 allows the data channel to operate in the usual manner until it receives a servo location signal from a comparator 72. Comparator 72 generates this signal when the value presented by a counter 73 matches the value present at the output of a servo location register 74. Register 74 contains all the servo sector locations for the various sets of data sectors.

Counter 73 counts VCO clock cycles from a VCO and data separator 68 during read mode, and counts generated data clock cycles from a data clock generator 75 during write mode. This insures that the data timing and control circuitry 71 will interrupt the data stream at the proper bit boundary.

In response to the servo location signal from comparator 72, data timing and control circuitry 71 opens switches 78 and 79. This interrupts the VCO cycles and generated data clock cycles to disk data controller 70 and to ENDEC 69.

This freezes the states of the disk data controller 70 and ENDEC 69, making each servo sector 30 transparent to the data channel.

Switch 77 is used only during write mode to put a preamp and write driver 66 in read mode to read a servo sector 30. Switch 76 is opened to prevent detected data from affecting the VCO 68. This has the effect of a VCO hold. Data timing and control circuitry 71 maintains switches 76-80 as positioned in FIG. 5 for a fixed time period until field 37. Switch 80 is used only during write mode to write VCO resync field 37 and code constraint field 38.

In write mode, switch 77 is closed first to enable writing of the VCO resync field 37. After field 37 is written, switch 80 is closed. In read mode, switch 76 is closed first to allow VCO 68 to resynchronize to the data. Switches 78 and 79 are closed when the VCO resync field operation is completed; i.e., is either written or read. The value in servo location register 74 is then updated with the location of the next servo sector 30. The channel again functions in the same manner as a prior art data channel until the next servo location signal is generated by comparator 72.

According to an important feature of the invention, the data and servo sectors work in concert such that the data channel is prepared for each servo sector 30 without requiring an address mark for that sector. To locate each servo sector only a servo start mark 34, which may be as short as 1 bit, is required. Each servo sector 30 can be located by open-loop timing from the previous servo sector and without any knowledge of the lengths or positions of the data sectors.

IV. APPLICATION TO CONSTANT LINEAR DENSITY (CLD) RECORDING

It will be understood that the sector servo system for CLD recording is essentially the same as described for banded recording, except that the clock frequency changes at each track and the length of each data sector will change from track to track. The manner in which the permissible combinations of servo sample rates and number of data sectors per track is computed is by an apparent modification of the algorithm described in the Appendix for banded recording.

V. APPLICATION TO CONVENTIONAL FBA FORMAT

A plurality of servo sectors are positioned and written at the factory. They are circumferentially spaced from each other on each track by an equal angle, which corresponds to a constant time separation. Since the data timing does not change in the FBA format, the allowed combinations of number of servo sectors and number of data sectors per track may be computed in the same manner as described in the Appendix for calculation of the allowed bands for banded recording.

Another approach is to choose a basic data unit that is of the same length as the length of the overhead fields. The allowed data record lengths would then be integral

multiples of the data unit length. If the servo sector spacing is chosen such that the distance between adjacent servo sectors is equal to an integral multiple of the data unit length, then the servo sectors will never lie in disallowed regions.

VI. APPLICATION TO CKD FORMAT

Again, servo sectors are positioned and written at the factory. The first data record on a given track is placed to start at an index mark, like 52. If the next servo sector lies within the write-read recover area, pad bits are added to the end of the record to insure that the next servo sector lies in the data region. If the next servo sector lies within a disallowed field at the start of the next data record, then pad bits are added to the end of the current record to align the next address mark with the next servo sector. This process is repeated for all sectors on the track. The controller generates the pad bits during a write operation and extracts the pad bits during a read operation, thus making said operations transparent to the host.

VII. APPLICATION TO TAPE DRIVES

While the invention has been illustrated as applied to disk drives, it will be apparent that the invention is equally applicable to tape drives. In both, the rate at which servo sectors for disk or servo sections for tape are sampled is independent of whether the disk or tape is formatted in FBA or CKD architecture.

In a tape drive, the allowable time separation between servo sections on a track and lengths of associated data sections on the tape is established such that at least some of the equally spaced servo sections on a given track are located within a data field of a data section and the rate at which the servo sections are sampled is independent of the data architecture used. Like the disk embodiments, the reading of a servo section is initiated based upon open-loop timing from the preceding servo section. The first servo section on each track commences at one common track index and each succeeding servo section is initiated at successive locations in equally spaced time increments from said index. Each servo section consists solely of bits containing position information and to each side thereof bits for controlling the interruption and restoration of the writing and reading of data. The ratio of servo sections is other than 1:1. At least some servo sections are located anywhere within a data field in a data section. At least some others of the equally spaced servo sections are within an identification field or immediately after an address indicating mark.

For a FBA formatted tape, the ratio of the time separation between data sections to the time separation between servo sections should again reduce to a ratio of small integers. For a CKD formatted tape, it will be necessary to add pad bits as described in Section VI.

As hereinafter used in the claims, the term "moving medium" is intended, unless otherwise indicated, to generically define either a magnetic, magneto-optical or optical disk or a magnetic or optical tape; the term "servo sections" is intended generically to cover servo sectors for disk files and servo sections for tape drives; and the term "data sections" is intended to generically define the data sectors for FBA and CLD formats and the variable length records for CKD format.

In the disk embodiments, the allowable number of servo sectors per revolution was calculated for each track or band of tracks. It will be apparent, however, that in view of the constant rotational speed of the disk, the time between each servo sector is constant. Hence, in both the disk and tape embodiments, the allowable time separation between servo sectors on a track is calculated, though in the disk embodiment this was expressed as allowable number of servo sectors on a track.

While the invention has been shown and described with respect to preferred embodiments thereof, it will be understood by those skilled in the art that changes in form and detail may be made in these embodiments without departing from the scope and teaching of the invention. Accordingly, the method and means herein disclosed are to be considered merely as illustrative, and the invention is to be limited only as specified in the claims.

APPENDIX

Computation of Permissible Servo Sample to Data Sector Combinations for Banded Recording in FBA Format

Assuming initially that the allowable linear density as a function of radius is known, the various fields are broken down into those portions which scale with linear density and those which do not. All references to bits are in message (non-encoded) bits; and the linear density units are kbpmm (kilobits per millimeter), also message bits. Assume further that

DB = number of data bits per sector (same for all bands for banded recording)
SB = number of servo bits (data rate dependent portion)
SF = fixed length portion of servo in μs
OB = number of bits in other fields (data rate dependent portion)
OF = fixed length portion of other fields in μs
P = rotational period in μs (i.e. 1/rpm)
M = number of data sectors in a band
N = number of servo samples per revolution
ld(r) = linear density in kbpmm, where r is the radius in mm

This Sheet Has Been Replaced

THIS SHEET HAS BEEN REPLACED

OH = fixed overhead

The minimum allowable ID radius for a band is then given by:

$$bits = \frac{(M \times (DB + OB) + N \times SB)}{1000}$$

$$OH = M \times OF + N \times SF$$

$$r = \frac{bits / ld(r)}{2\pi\left(1 - \frac{OH}{P}\right)}$$

$$ld(r) = \frac{bits}{2\pi\left(1 - \frac{OH}{P}\right)}$$

Where ld(r) is a constant,

$$ld(r) = B,$$

$$r = \frac{bits}{2\beta\pi\left(1 - \frac{OH}{P}\right)}$$

and where ld(r) is linear:

$$ld(r) = Ar + B,$$

$$r = \frac{-B + \sqrt{B^2 \frac{4Abits}{2\beta\pi\left(1 - \frac{OH}{P}\right)}}}{2A}$$

Usually the linear density decreases with increased radius, therefore $A < 0$ and $B > 0$. In this case, the positive root of the quadratic yields the smaller radius (the negative root occurs where the decreasing linear density is compensated for by the increasing circumference of the track).

Once the minimum allowable ID radius has been computed, the actual relationship between the positions of servo sectors 30 and data sectors M must be computed to

determine if the band is valid; i.e., that the servo samples N occur only in the allowed positions.

To determine the allowed bands:

1. Choose a servo sample rate. (For example, 60.)
2. Compute the band with the greatest number of data sectors, whose minimum allowable ID radius is less than or equal to the disk ID. (For example, assume the result is 31 data sectors).
3. Starting with this band, check to see if it is valid. If not, decrease the sector count by 1 and repeat. (Thus, decrease from 31 to 30.) Note that if the sector count goes to 0 without success, there is no allowable ID band under these conditions.
4. Start with the first band whose minimum allowable ID radius is greater than the disk ID. (This could be 30 data sectors as a result of the example used for step 3.)
5. See if the band is valid, if so, add it to the list. Increase the sector count by 1 and repeat until the minimum allowable ID radius is greater than or equal to the disk OD. (Again, using the example from the prior steps, step 5 could give the following numbers of data sectors per band: 30, 35, 36, 40, 42, 45, 48, 50 and 54, of which for simplified illustration only four, A-D, are shown, in FIG. 4)

* C L M S *

CLAIMS

1 A magnetic recording disk, the magnetic recording surface of the disk being divided into a plurality of radially-spaced bands of concentric data tracks, all of the data tracks in each band being divided into the same number of data sectors and into a plurality of generally equally angularly spaced servo sectors, the number of servo sectors in a data track being the same for all data tracks in the bands and the number of data sectors in a data track of each band being different from the number of data sectors in a data track in the other of the bands, but each data sector in each band containing the same number of data bits, all of the generally equally angularly spaced servo sectors in each of the data tracks of the bands being generally radially aligned with the generally equally angularly spaced servo sectors in the other data tracks of the bands, whereby the servo sectors extend generally radially across the bands.

2 The disk according to claim 1 wherein if the number of data sectors per data track for each of the bands is represented by the variable M and the number of servo sectors per data track is represented by the constant N for each of the bands is equal to a ratio of two integers, each integer being between 1 and 12.
