

ROCK BIT HAVING A FLEXIBLE METAL FACED SEAL

BACKGROUND

Technical Field

[01] The present invention relates to earth boring bits, and more particularly to those having rotatable cutters, also known as cones.

Description of Related Art

[02] Earth boring bits with rolling element cutters have bearings employing either rollers as the load carrying element or with a journal as the load carrying element. The use of a sealing means in such rock bit bearings has dramatically increased bearing life in the past fifty years.

[03] Early seals for rock bits were designed with a metallic Belleville spring clad with an elastomer, usually nitrile rubber (NBR). The metallic spring provided the energizing force for the sealing surface, and the rubber coating sealed against the metal surface of the head and cone and provided a seal on relatively rough surfaces because the compliant behavior of the rubber coating filled in the microscopic asperities on the sealing surface. Belleville seals of this type were employed mainly in rock bits with roller bearings. The seal would fail due to wear of the elastomer after a relatively short number of hours in operation, resulting in loss of the lubricant contained within the bearing cavity. The bit would continue to function for some period of time utilizing the roller bearings without benefit of the lubricant.

[04] A significant advancement in rock bit seals came when o-ring type seals were introduced. These seals were composed of nitrile rubber and were circular in cross section. The seal was fit into a radial gland formed by cylindrical surfaces between the head and cone bearings, and the annulus formed was smaller than the original dimension as measured as the cross section of the seal. The o-ring seal was then radially squeezed between the cylindrical surfaces.

[05] To minimize sliding friction and the resultant heat generation and abrasive wear, rotating O-rings are typically provided with a minimal amount of radial compression. However, reciprocating (Belleville) seals must have a much larger radial compression to exclude contamination from the sealing zone during axial sliding (typically about twice the

compression). The rock bit seal must both exclude contamination during relative head/cone axial motion and minimize abrasive wear during rotation.

[06] Reference is now made to FIGURE 1 which illustrates a prior art configuration for an earth boring bit. FIGURE 2 illustrates a close-up view of the prior art configuration focusing on the area of a sealing system 2 associated with a rotating cone 4 installed on a shaft 6 of a bit head 8. An o-ring seal 10 is inserted into a seal gland 12 and squeezed between a cone sealing surface 14 and a head sealing surface 16.

[07] Reference is now made to FIGURE 3 which illustrates a prior art configuration for an earth boring bit. FIGURE 4 illustrates a close-up view of the prior art configuration focusing on the area of a sealing system 22 associated with a rotating cone 24 installed on a shaft 26 of a bit head 28. A first ring 30 is press-fit into a gland 32 formed in the cone 24. The first ring 30 presents a first metal seal face 34. A second ring 36 is also placed in the gland 32. The second ring 36 presents a second metal seal face 38. An energizing structure 40 is also placed in the gland 32 and configured to apply a combination of axial and radial force against a back surface 42 of the second ring 36 so as to urge the second metal seal face 38 into contact with the first metal seal face 34. The structure shown in Figure 4 illustrates the well-known single energizer type of metal faced sealing system.

[08] In all configurations of metal faced sealing structures, the sealing system 22 must be provided with sufficient force through the energizing structure 40 to maintain sufficient sealing contact (between the second metal seal face 38 and first metal seal face 34) and further to overcome any pressure differential between internal and external zones. Pressure differentials between those zones fluctuate as the cone is contorted on the bearing during operation. This phenomenon is known in the art as "cone pumping." Cone pumping throws an internal pressure surge at the metal faced bearing seal which can lead to catastrophic failure of the seal over time. In addition, changes in depth while the bit is in use can cause fluctuations in pressure between the internal pressure and the external pressure. Conversely, application of too much force on the seal by the energizing structure 40 can cause difficulties in assembling the cone to the bearing and may result in accelerated wear of the first and second rings 30 and 36. It is important that the metal seal faces 34 and 38 are flat, and so a lapping of the surfaces is often provided (in the light band range).

[09] A significant challenge with the single energizer type of metal faced sealing

system shown in Figure 4 is that the press fitting of the first ring 30 in the cone gland 32 may deform the first ring and produce a “waviness” in the first metal seal face 34. The second ring 36 with second metal seal face 38 must overcome this surface waviness through the force applied by the energizing structure 40 so as to maintain the desired sealing contact (otherwise the seal will leak).

[010] An additional challenge with the single energizer type of metal faced sealing system shown in Figure 4 is that the elastomeric energizing structure 40 is offset so as to apply force to the second ring 36 not only in the preferred axial direction but also in the radial direction. The sealing force is accordingly dissipated by the wasted force component applied in the radial direction. The radially applied force component further introduces a torque on the second ring 36 which reduces (i.e., narrows) the radial width of the effective sealing surface where the metal seal faces 34 and 38 make sealing surface contact. The reduction in width arises because the introduced torque causes a distortion of the seal ring producing an out-of-flatness surface condition on the sealing face of the seal ring.

[011] Yet another challenge with the single energizer type of metal faced sealing system shown in Figure 4 is that the metal seal faces 34 and 38 become unloaded as a result of an increase in grease pressure. For example, rock bit bearings may operate with an internal pressure greater than the environment. As a result, grease leakage may occur.

[012] Notwithstanding the foregoing challenges, metal faced sealing systems are often used in roller cone drill bits which operate at higher RPM drilling applications because the metal seal faces 34 and 38 resist wear and consequently exhibit longer operating life than a standard O-ring type sealing system like that shown in Figures 1 and 2.

[013] The foregoing challenges remain an issue and thus a need exists in the art for an improved metal faced sealing system for use in rock bits.

SUMMARY

[014] In an embodiment, a sealing system for a drill bit including a shaft region and a rotating cone comprises: a first annular gland defined in the rotating cone; a first ring retained within the first annular gland and having a first metal seal face; a second annular gland defined at a base of the shaft region; a second ring retained within the second annular gland; a third ring positioned between the first and second rings, said third ring including a

sealing region with a second metal seal face in contact with the first metal seal face, a body region including a biasing surface axially opposite the second metal seal face, and an axially extending flexible member pivotally interconnecting the sealing region to the body region; a spring member inserted within the first gland and configured to apply an axial force against the biasing surface of the third ring; and a radial drive connection between second ring and third ring.

[015] In another embodiment, a sealing system for a drill bit including a shaft region and a rotating cone comprises: a first annular gland defined in the rotating cone; a first ring mounted in the first annular gland and having a first metal seal face; a second ring mounted to the shaft region; a third ring positioned between the first and second rings, said third ring including a sealing region with a second metal seal face in contact with the first metal seal face, a body region with a biasing surface axially opposite the second metal seal face, and a flexible member pivotally coupling the sealing region to the body region; and a biasing system configured to apply an axial force against the biasing surface of the third ring.

[016] In another embodiment, a sealing system for a drill bit including a shaft region and a rotating cone comprises: an annular gland defined in the rotating cone; a first ring mounted in the annular gland and having a first metal seal face; a second ring inserted in the annular gland and including a sealing region with a second metal seal face in contact with the first metal seal face, a body region with a biasing surface axially opposite the second metal seal face, and a flexible member pivotally coupling the sealing region to the body region; an O-ring compressed by a sealing surface of the second ring body region to define a static seal; and a biasing system configured to apply an axial force against the biasing surface of the third ring.

BRIEF DESCRIPTION OF THE DRAWINGS

[017] Other features and advantages of the invention will become clear in the description which follows of several non-limiting examples, with references to the attached drawings wherein:

[018] FIGURE 1 illustrates a prior art configuration for an earth boring bit with a conventional O-ring type sealing system;

[019] FIGURE 2 illustrates a close-up view of the prior art configuration of

FIGURE 1 focusing on the area of the seal;

[020] FIGURE 3 illustrates a prior art configuration for an earth boring bit with a conventional single energizer metal faced sealing system;

[021] FIGURE 4 illustrates a close-up view of the prior art configuration of FIGURE 3 focusing on the area of the seal;

[022] FIGURES 5A and 5B illustrate an embodiment of a metal faced sealing system; and

[023] FIGURE 6 illustrates an embodiment of a metal faced sealing system.

DETAILED DESCRIPTION OF THE DRAWINGS

[024] FIGURES 1-4 have previously been described.

[025] Reference is now made to FIGURE 5A which illustrates a cross-sectional view of an embodiment of a metal faced sealing system 100. The sealing system 100 is associated with a rotating cone 102 installed on a shaft region 104. The sealing system 100 is suitable for use in any sealing application including implementations where the cone is supported for rotation using a journal bearing or a roller bearing as well known to those skilled in the art.

[026] The sealing system 100 is provided within a gland structure formed in the cone 102 and at a base of the shaft region 104. The gland structure includes a first gland 106 formed in the cone and a second gland 108 formed in the base of the shaft region 104. The first gland 106 is an annular structure defined by a radial surface 110 extending outwardly into the body of the cone 102 perpendicularly away from the axis of cone rotation and a cylindrical surface 112 extending perpendicularly and rearwardly from the radial surface towards a bottom surface (base) 114 of the cone in a direction parallel to the axis of cone rotation. The shaft region 104 is defined by a cylindrical shaft surface 116 to which the cone 102 is mounted (in a manner conventional and known to those skilled in the art) and a radial surface 118 at the base of the shaft region extending outwardly from the cylindrical journal surface 116 perpendicularly away from the axis of cone rotation. The second gland 108 is an annular channel-like structure defined in the radial surface 118 at the base of the shaft region 104 by a pair of cylindrical (channel side) surfaces 120 and 122 and a radial (channel bottom) surface 124 interconnecting the cylindrical surfaces 120 and 122 at a bottom of the annular

structure. In this configuration, it will be noted that the second gland opens into the first gland.

[027] The sealing system 100 further comprises a first ring 130 (having a generally square or rectangular cross-section) press fit into the first gland 106 against the radial surface 110 and cylindrical surface 112 at a corner where the surfaces 110 and 112 meet. An inner diameter of the first ring 130 defined by surface 132 is offset from the cylindrical surface 116 of the shaft region 104. The first ring 130 further includes a first metal seal face (using a radially extending surface) 134.

[028] The sealing system 100 further comprises a second ring 140 (having an irregular cross-section) forming a housing member that includes a central body region 142, a rear region 144 extending rearwardly and axially from the central body region, a flange region 146 extending inwardly and radially from the central body region and a front region 148 extending frontwardly and axially from the central body region. The rear region 144 of the second ring 140 is press fit into the second gland 108 against the radial surface 124 and cylindrical surface 120 at a corner where the surfaces 124 and 120 meet. The flange region 146 and front region 148 of the second ring 140 form part of a third gland 150 comprising an annular structure defined by a radial surface 152 defined by the flange region 146 extending outwardly perpendicularly away from the axis of cone rotation and a cylindrical surface 154 defined by the front region 148 extending perpendicularly and frontwardly from the radial surface towards an end of the second ring 140 in a direction parallel to the axis of cone rotation.

[029] The sealing system 100 further comprises a third ring 170 (having an irregular cross-section) that includes a sealing region 171 with a second metal seal face (using a radially extending surface) 172 including a first portion 172a and a second portion 172b. The first and second portions 172a and 172b are coaxial and are separated from each other by an annular channel 174. The annular channel 174 forms a non-contacting region of the seal face that serves to separate the functions of first portion 172a and second portion 172b. The width of channel 174 is selected to ensure improved contact by the first portion 172a. A plurality of radially extending channels 184 are provided in the second portion 172b of the second metal seal face 172 to extend between an inner circumference 186 of the third ring 170 and the annular channel 174. The channels 184 support provision of pressure equalization between

the channel 174 and the grease side of the seal at reference 186. Pressure equalization is desired so that the second portion 172b will function as a bearing surface (not a sealing surface) while the first portion 172a functions as a sealing surface (having a pressure differential).

[030] FIGURE 5B (not drawn to scale) shows the angular distribution of the channels 184 about the inner circumference of the second portion 172b. The second portion 172b of the second metal seal face 172 is accordingly circumferentially discontinuous and thus does not participate in forming the seal (while the first portion 172a is circumferentially continuous and thus responsible for providing the sliding sealing surface). In the illustrated embodiment, there are twelve channels 184, so that the angular offset between channels is thirty degrees. In another implementation, sixteen channels 184 may be provided. Fewer or more channels may be provided in accordance with a desired design (perhaps based on the diameter of the cone and diameter of the gland 106).

[031] The second metal seal face 172 is positioned in sliding/sealing contact with the first metal seal face 134. The sealing contact is made between the first portion 172a of the second metal seal face 172 and the first metal seal face 134 of the first ring 130.

[032] The third ring 170 further includes a body region 173. Axially opposite the second metal seal face 172, the body region 173 includes a biasing surface 176. In the illustrated embodiment, the biasing surface 176 is provided at the distal end of a radially extending biasing projection member 178. Also axially opposite the second metal seal face 172, the third ring 170 further includes a rear surface 180.

[033] The body region 173 includes surfaces which assist in defining the third gland 150 by presenting an annular structure defined by a radial surface 192 extending outwardly perpendicularly away from the axis of cone rotation and a cylindrical surface 194 extending perpendicularly and rearwardly from the radial surface toward the surface 176 parallel to the axis of cone rotation.

[034] An O-ring sealing member 200 (for example, with a circular cross-section) is inserted within the third gland 150 and radially compressed between the cylindrical surface 154 of the second ring 140 and the cylindrical surface 194 of the third ring 170. The O-ring sealing member 200 may further be axially compressed between the radial surface 152 of the second ring 140 and the radial surface 192 of the third ring 170. The compressed O-ring

sealing member 200 forms a static seal between the grease side and exterior (for example, mud) side of the sealing system 100. The sliding seal between the grease side and exterior side is provided by the opposed first and second metal seal faces 134 and 172, respectively.

[035] The sealing region 171 is coupled to the body region 173 by an axially extending flexible member 175. The flexible member 175 permits the sealing region 171 of the third ring 170 to pivot relative to the body region 173 of the third ring. The supporting pivoting action allows the angular contact of the second metal seal face 172 to vary so as to better conform to the first metal seal face 134 (for example, in the case of waviness of the seal face 134 resulting from press-fitting of the first ring 130 within the first gland 106). The flexibility of the member 175 arises from having a small (thin) radial dimension and a significantly long axial dimension (length). Selection of the radial thinness and axial length may be made by the designer in dependence on an analysis of the relative angular stiffness of the sealing region 171 to the expected circumferential flatness of the surface 134.

[036] An energizing structure 206 is installed within the first gland 106 between the third ring 170 and the shaft region 104. The energizing structure 206 engages the radial surface 118 at the base of the shaft region 104 and further engages the biasing surface 176 of the third ring 170. Thus, the energizing structure 206 is compressed between the radial surface 118 and the biasing surface 176. In this configuration, the energizing structure 206 functions to apply an axially directed force against the third ring 170 so as to maintain sliding/sealing contact between the first metal seal face 134 of the first ring 130 and the second metal seal face 172 of the third ring 170.

[037] In a preferred implementation, the energizing structure 206 comprises a Belleville spring member 208 (or any suitable conical spring washer device) and a force transfer ring 210. The Belleville spring member 208 includes an outer peripheral edge 212 which engages the radial surface 118 at the base of the shaft region 104 through the force transfer ring 210. An inner peripheral edge 214 of the Belleville spring member 208 engages the biasing surface 176 of the third ring 170. Importantly, this biasing surface 176 which receives the axially asserted biasing force on the third ring is radially located at approximately the radial center of the second metal seal face 172 of the third ring so as to equalize the force applied through the flexible member 175 and the first portion 172a and a second portion 172b of the second metal seal face 172 against the first metal seal face 134,

and more importantly ensure sufficient force applied by the first portion 172a to maintain the sealed relationship with the first metal seal face 134.

[038] With respect to applying drive torque, a number of technical implementations may be utilized. In a preferred embodiment, a radially extending drive connection (schematically shown at reference 230) is provided to interconnect the second ring 140 and third ring 170. The radially extending drive connection 230 may take the form of a plurality of circumferentially spaced drive pins which radially extend through passages formed in second ring 140 and third ring 170. For example, a drive pin may extend radially outwardly through an axial slot formed in the third ring 170 into an opening formed along the inner circumference of the second ring 140 (for example, at or about the region 146). In an alternative implementation, inner edge 214 of the spring member 208 may include one or more circumferentially placed notches, with a rearwardly and axially extending projection from the surface 176 of the third ring 170 received by and engaging a corresponding notch. Likewise, the notches may be formed in the outer edge 212 to receive projections extending axially from the force transfer ring 210 (or alternatively extending axially from the second ring 140). The notch-projection configuration for the spring member 208 would accordingly present an axially extending drive connection 231 for applying drive torque.

[039] Reference is now made to FIGURE 6 which illustrates a cross-sectional view of an embodiment of a metal faced sealing system 100. The embodiment of FIGURE 6 is similar to the embodiment of FIGURE 5A and like reference numbers refer to like or similar parts for which no further discussion will be provided. With respect to those parts, reference is made to the description of FIGURE 5A. The embodiment of FIGURE 6 differs from the embodiment of FIGURE 5A primarily in the configuration of the energizing structure 206'.

[040] The energizing structure 206' is installed within the first gland 106 between the third ring 170 and the shaft region 104. The energizing structure 206' engages the radial surface 118 at the base of the shaft region 104 and further engages the biasing surface 176 of the third ring 170. Thus, the energizing structure 206' is compressed between the radial surface 118 and the biasing surface 176. In this configuration, the energizing structure 206' functions to apply an axially directed force against the third ring 170 so as to maintain sliding/sealing contact between the first metal seal face 134 of the first ring 130 and the second metal seal face 172 of the third ring 170.

[041] In a preferred implementation, the energizing structure 206' comprises a Belleville spring member 208' (or any suitable conical spring washer device). The Belleville spring member 208' includes an outer peripheral edge 212 which engages the radial surface 118 at the base of the shaft region 104. An inner peripheral edge 214 of the Belleville spring member 208' engages the biasing surface 176 of the third ring 170. It will be noted that the orientation of the Belleville spring member 208' is opposite that of the member 208 in FIGURE 5A. With this configuration, the transfer ring 210 is not required. Again, the axial force is applied to the biasing surface 176 at a radial position which substantially radially corresponds to the flexible member 175 and a radial center of the second metal seal face 172.

[042] Considering the driving torque to the seal, in an alternative implementation, the inner edge 214 of the spring member 208' may include one or more circumferentially placed notches, with a rearwardly and axially extending projection from the surface 176 of the third ring 170 received by and engaging a corresponding notch. Likewise, the notches may be formed in the outer edge 212 to receive projections extending axially from the surface 118. The notch-projection configuration for the spring member 208' would accordingly present an axially extending drive torque connection 231' for applying drive torque.

[043] Although FIGURE 5A shows the biasing surface 176 as a separate surface from the rear surface 180 of the third ring 170, it will be understood that the biasing surface 176 and rear surface 180 may, in the alternative embodiment of FIGURE 6, comprise a same surface of the third ring 170 against which the axially directed force is applied to maintain the sealing relationship between the first and second metal seal faces 134 and 172, respectively.

[044] While the implementations of FIGURES 5A and 6 show the mounting of the second ring to shaft region 104 using the second gland 108, it will be understood that in an alternative embodiment the ring 140 may comprise the regions 142, 146 and 148 with region 142 mounted to the shaft region 104 using any suitable mounting means (including, for example, a welded attachment to surface 118). Likewise, the first ring 130 may alternatively be mounted within the first gland 106 using any suitable mounting means (including, for example, a welded attachment).

[045] While a Belleville spring member is exemplary implementation for the energizing structure, it will be understood that other forms of energizing structures, such as, for example, coiled springs, could instead be used in applying the axial force to the biasing

surface 176.

[046] Although preferred embodiments of the method and apparatus have been illustrated in the accompanying Drawings and described in the foregoing Detailed Description, it will be understood that the invention is not limited to the embodiments disclosed, but is capable of numerous rearrangements, modifications and substitutions without departing from the spirit of the invention as set forth and defined by the following claims.

WHAT IS CLAIMED IS:

1. A sealing system for a drill bit including a shaft region and a rotating cone, comprising:

a first annular gland defined in the rotating cone;

a first ring retained within the first annular gland and having a first metal seal face;

a second annular gland defined at a base of the shaft region;

a second ring retained within the second annular gland;

a third ring positioned between the first and second rings, said third ring including a sealing region with a second metal seal face in contact with the first metal seal face, a body region including a biasing surface axially opposite the second metal seal face, and an axially extending flexible member pivotally interconnecting the sealing region to the body region;

a spring member inserted within the first gland and configured to apply an axial force against the biasing surface of the third ring; and

a radial drive connection between second ring and third ring.

2. The sealing system of claim 1, wherein the shaft region includes a cylindrical surface and a radial surface extending perpendicular from the cylindrical surface, and wherein the second gland is formed in the radial surface of the shaft region.

3. The sealing system of claim 1, further comprising:

a third annular gland formed between the second ring and third ring; and

an O-ring sealing member compressed within the third annular gland.

4. The sealing system of claim 1, wherein the shaft region includes a cylindrical surface and a radial surface extending perpendicular from the cylindrical surface, and wherein the spring member includes a first edge which engages the radial surface of the shaft region and a second edge which engages the biasing surface of the third ring.

5. The sealing system of claim 1, wherein the biasing surface is located at a distal end of an axially extending member projecting from a rear surface of the third ring.

6. The sealing system of claim 1, wherein the second metal seal face on the third ring comprises a pair of coaxially arranged surface portions separated from each other by an annular channel.

7. The sealing system of claim 6, wherein a first one of the pair of coaxially arranged surface portions is in sliding and sealing configuration with the first metal seal face on the first ring.

8. The sealing system of claim 7, wherein a second one of the pair of coaxially arranged surface portions includes a plurality of radially extending channels connected to the annular channel.

9. The sealing system of claim 1, wherein the spring member is a Belleville spring.

10. The sealing system of claim 1, further including a fourth ring inserted within the first gland, and wherein the spring member includes a first edge which engages the fourth ring and a second edge which engages the biasing surface of the third ring.

11. A sealing system for a drill bit including a shaft region and a rotating cone, comprising:

a first annular gland defined in the rotating cone;

a first ring mounted in the first annular gland and having a first metal seal face;

a second ring mounted to the shaft region;

a third ring positioned between the first and second rings, said third ring including a sealing region with a second metal seal face in contact with the first metal seal face, a body region with a biasing surface axially opposite the second metal seal face, and a flexible member pivotally coupling the sealing region to the body region; and

a biasing system configured to apply an axial force against the biasing surface of the third ring.

12. The sealing system of claim 11, further including a drive connection between

the second ring and the third ring.

13. The sealing system of claim 11, wherein the shaft region includes a cylindrical surface and a radial surface extending perpendicular from the cylindrical surface, and further comprising a second annular gland formed in the radial surface at a base of the shaft region, wherein the second ring is press-fit into the second gland.

14. The sealing system of claim 11, wherein the shaft region includes a cylindrical surface and a radial surface extending perpendicular from the cylindrical surface, and wherein the biasing system comprises a spring configured to engage the radial surface of the shaft region and engage the biasing surface of the third ring.

15. The sealing system of claim 11, wherein second metal seal face on the third ring comprises a pair of coaxially arranged surface portions separated from each other by an annular channel, and wherein a first one of the pair of coaxially arranged surface portions is in sliding and sealing configuration with the first metal seal face on the first ring.

16. The sealing system of claim 15, wherein a second one of the pair of coaxially arranged surface portions includes a plurality of radially extending channels connected to the annular channel.

17. The sealing system of claim 11, further comprising:
a third annular gland formed between the second ring and third ring; and
an O-ring sealing member compressed within the third annular gland.

18. A sealing system for a drill bit including a shaft region and a rotating cone, comprising:

an annular gland defined in the rotating cone;
a first ring mounted in the annular gland and having a first metal seal face;
a second ring inserted in the annular gland and including a sealing region with a second metal seal face in contact with the first metal seal face, a body region with a biasing surface axially opposite the second metal seal face, and a flexible member pivotally coupling the sealing region to the body region;

an O-ring compressed by a sealing surface of the second ring body region to define a static seal; and

a biasing system configured to apply an axial force against the biasing surface of the third ring.

19. The sealing system of claim 18, wherein the biasing surface is a radially extending surface which is perpendicular to an axis of cone rotation and the axial force is applied perpendicular to the radially extending surface.

20. The sealing system of claim 18, wherein second metal seal face on the third ring comprises a pair of coaxially arranged surface portions separated from each other by an annular channel, and wherein a first one of the pair of coaxially arranged surface portions is in sliding and sealing configuration with the first metal seal face on the first ring.

21. The sealing system of claim 20, wherein a second one of the pair of coaxially arranged surface portions includes a plurality of radially extending channels connected to the annular channel.

22. The sealing system of claim 18, wherein the biasing system comprises a Belleville spring member engaging the biasing surface.

23. The sealing system of claim 18, wherein the shaft region includes a cylindrical surface and a radial surface extending perpendicular from the cylindrical surface at a base of the rotating cone, and wherein the biasing system in a spring member compressed between the radial surface of the shaft region and the biasing surface of the second ring.
