A DOOR ASSEMBLY

The present invention relates to a door and door assembly. The invention has been developed especially, but not exclusively for internal
 5 access doors for residential or commercial use and the invention is herein described in that context. However it is to be appreciated that the invention has broader application and is not limited to that particular use.

Throughout the specification the term "door" is used to describe any structure that is operable to cover an opening and includes gates, shutters
 10 covers and the like. Moreover, throughout the specification the invention is described with reference to the orientation for use in internal access doors where the plane of the door is generally vertical. This however should not be construed as limiting the invention to that orientation, as the door may be used in other orientations. Accordingly, reference to a particular orientation
 15 is to be construed to encompass these other orientations.

In the design and construction of buildings, there is a continuing trend to maximise or increase the useable space. As a result, there is a continuing need for products which can allow savings in space, or be used in confined spaces. An aim of the present invention is to provide a door and
 20 door assembly which addresses this need.

In a first aspect, the present invention provides a door including a first panel adapted to be rotatably mounted to a support structure, and a second panel which is connected to, and rotatable with the first panel. The second panel is disposed generally parallel to, or co-planar with, the first panel and
 25 is moveable thereto in the plane of the panels such that the second panel is moveable relative to the first panel between a retracted position where the second panel is generally laterally adjacent to the first panel and an extended position where the second panel is spaced from the first panel in the plane of the panels.

30 A main advantage of the door according to the present invention is that the space required to allow the door to swing between an open and a

closed position where the door covers an opening is substantially reduced as compared to conventional hinge doors for an opening of comparable size. This advantage comes about as the door can be rotated whilst the second panel is in the retracted position and then moved to an extended position
5 once the door has rotated to its closed position.

The panels of the door may be of any suitable shape though in most applications it is envisaged that they will be generally planar and have a rectangular profile which includes opposite ends which are spaced apart and interconnected by opposite sides. In this arrangement, preferably the first
10 panel is adapted to be rotatably mounted to the support structure about an axis which extends generally in the direction of the opposite sides of the first panel and preferably the second panel is moveable relative to the first panel in a direction transverse to this axis.

Typically in the above arrangement, the door includes a hinge or
15 similar linkage which allows the door to pivot about one of its sides and in a preferred form, the sides of the first panel are generally parallel to the sides of the second panel.

In a preferred form, the door further includes a latching device which is operative to couple the first and second panels together so as to maintain
20 the second panel in its retracted position. Preferably the latching device further includes a release mechanism which is operable to release the second panel so as to enable the panels to be moved to its extended position. In a particularly preferred form, the release mechanism is adapted to the operatively associated with the support structure such as door jamb or
25 the like so as to automatically release the second panel on rotation of the first panel to a predetermined position relative to the support structure.

In one form, the latching device includes a bar which is moveable between an engaged position wherein it interconnects the first and second panels to inhibit relative movement of the panels, to a release position where
30 the bar is remote from the second panel. Preferably the latching device further includes a biasing spring to bias the bar into its engaged position.

Preferably the first panel further includes a retaining device which is operable to engage with the support structure so as to retain the first panel in a predetermined position relative to the support structure. Typically this pre-determined position will be when the panel is in a closed position relative to a door frame. In one form, the retaining device includes a biasing spring clip which is operable to be released on application of manual pressure to the first panel in a direction to rotate the door about the support structure from its predetermined position. This arrangement has the advantage that it facilitates easy release and engagement of the retaining device, without the need for separate manual activation of the retaining device to release the door to enable it to be rotated.

Preferably the first and second panels are interconnected by at least one track assembly which includes a track, and a runner which is captured within the track and slidable therein. In this arrangement the track is fixed to one of the first or second panels and the runner is connected to the other of the second panels.

In a preferred form, the door includes a pair of track assemblies, a respective one disposed at each of the opposite ends of the panels.

In a further aspect, the present invention relates to a door assembly which includes a door frame which defines an opening and a door of the above form. Specifically, in this further aspect, the door assembly includes a first generally planar panel which is rotatably mounted to the door frame and moveable between an open and a closed position, and a second panel which is connected to, and rotatable with, the first panel. The second panel is disposed generally parallel to, or co-planar with the first panel and moveable thereto in the plane of the panels such that the second panel is moveable relative to the first panel between a retracted position wherein the second panel is generally laterally adjacent to the first panel, to an extended position wherein the second panel is spaced from the first panel in the direction of the panels. In this arrangement, the door assembly is operative to cover the opening defined by the door frame by movement of the first

panel from its open to its closed position, and movement of the second panel from its retracted to its extended position.

Preferably the door assembly further includes a latching device which is operative to couple the first and second panels together so as to maintain
5 the second panel in its retracted position. Preferably the latching device further includes a release mechanism which is operative to release the second panel so as to enable the panels to be moved to its extended position. In a particularly preferred form, the release mechanism is adapted to be operatively associated with the door frame so as to automatically
10 release the second panel on rotation of the first panel to its closed position.

Preferably the latching device includes a bar which is moveable between an engaged position wherein it interconnects the first and second panels to inhibit relative movement of the panels, to a release position where the bar is remote from the second panel. Preferably the latching device
15 includes a biasing spring to bias the bar into its engaged position, and wherein the bar is adapted to move from the engaged position to the release position by engagement of the bar with an abutment surface connected to, or integrally formed with the door frame on movement of the first panel to the closed position.

20 Preferably the door assembly further includes a retaining device which is operable to couple the first panel to the door frame so as to retain the first panel in the closed position. Preferably the retaining device includes a spring biasing clip which is operable to be released on the application of manual pressure to the first panel to rotate the door from the closed to its
25 open position. Preferably the first and second panels are interconnected by a track assembly located at or adjacent an upper end of the respective panels. Preferably the track assembly includes a first track mounted on the first panel and a runner which is connected to the second panel and which is captured within the first track and slidable therein. Preferably a second track
30 is connected to the door frame, and wherein on movement of the first panel to the closed position, the second track is adapted to align with the track on

the first panel so as to enable the runner connected to the second panel to slide between the first and second tracks.

An advantage of a preferred form of the present invention is that the door is easy to operate. In particular, the second panel is adapted to be
5 retained in its retracted position by the latching device when the door is other than in its closed position. Furthermore when the door is moved to its closed position it is retained in that position to thereby facilitate alignment of the track on the first panel with the track located on the door frame, thereby enabling easy movement of the second panel from its retracted to its
10 extended position. Furthermore by having a track assembly located at the lower end of the panels ensure, that the panels remain generally in their parallel alignment.

It will be convenient to hereinafter describe an embodiment of the present invention with reference to the accompanying drawings. It is to be
15 appreciated that the particularity of this description is not to be understood as superseding the generality of the preceding broad description of the invention.

In the drawings:

Figure 1 is a partial perspective view of a door according to an
20 embodiment of the invention and which incorporates an associated door frame shown in partial phantom view;

Figure 2 is an elevation of the door of Figure 1 in an open position;

Figure 3 illustrates the door of Figure 1 when in a closed position;

Figure 4 is a bottom end view of the door of Figure 1;

25 Figure 5 is a sectional edge view of the top of the door of Figure 2;

Figure 6 is a sectional view along section line vi-vi of Figure 3;

Figure 7 is a sectional view along section line vii-vii of Figure 3; and
Figures 8 to 10 illustrate a plan view of the operation of the door of Figure 1 to move from an open to a closed position.

30 In relation to Figure 1, a door 10 is disclosed which includes a first panel 11 and a second panel 12. The door is mounted to a door frame 13,

which in Figure 1 is only partially disclosed in phantom so as not to obscure the features of the door 10.

Both the first and second panel are generally planar and of rectangular shape having opposite ends 14, 15, 16 and 17 which are
5 interconnected by opposite sides 18, 19, 20 and 21. The panels are interconnected so as to be in parallel alignment by a track rail assembly 22. The assembly 22 includes a track 23 fixed adjacent to an upper end 14 of the first panel 11 and a rail 24 extends from the upper end 16 and is captured within the track 23 so that the second panel is slidable relative to
10 the first panel in the plane of the panels.

The first panel 11 is adapted to be hingedly mounted to the door frame 13 so as to be rotatable about a generally vertical axis 25 which extends along an inner side 18 of the first panel. In the illustrated form, the door 10 is connected to the door frame by hinges 26 and 27 as illustrated in
15 Figure 3. It is to be appreciated that any other form of appropriate coupling could be used.

As illustrated in Figure 4, a second track assembly 28 is located at the bottom end of the first and second panels. In this arrangement, a track 29 having a generally C shaped profile is mounted on the bottom end 17 of
20 the panel 12 and a guide runner 30 is mounted on the bottom end 15 of the first panel. The guide runner includes a wheel 31 which is received within the C shaped track. This arrangement prevents the panels from splaying apart at their lower end.

The second panel 12 is slidable relative to the first panel in the track
25 assemblies 22, 28 between a retracted position where the panels are laterally adjacent and an extended position where the second panel is spaced from the first panel in the plane of the panels. Figure 1 illustrates the second panel in a mid position between its retracted and extended positions. A plan view of the door with the second panel in the retracted
30 position is illustrated in Figure 9 whereas Figure 10 illustrates the second panel 12 in its extended position.

The door 10 further includes a latching device 32 which is operable to retain the second panel in its retracted position. The device is mounted on the front side 19 of the first panel 11 and includes a spring biased bar 33 (as illustrated in Figure 5) which is mounted in a housing 34 fixed to the first
5 panel. The bar 33 is biased to extend out from the housing 34 so as to extend across the front side 21 of the second panel to thereby prevent that panel from sliding in the track assemblies 22 and 28 from its retracted position to its extended position. With this arrangement, the door is operable to be able to be easily pivoted about the hinges 26 and 27 whilst
10 retaining the second panel in its retracted position.

Turning to Figures 8 to 10, the first panel 11 is arranged to be pivoted about the hinges 26 and 27 relative to the door frame 13 from an open position (as shown in unbroken line in Figure 8) where the door extends across the plane of the opening 35 defined by the door frame 13, to a closed
15 position (as shown best in Figure 9) where the door is in the plane of the opening 35.

With the second panel in the retracted position, movement of the first panel from the open to the closed position does not entirely cover the opening 35, this being achieved by the movement of the second panel from
20 its retracted position to its extended position as best illustrated in Figure 10. The various positions of the door are also shown in Figures 2 and 3 where in Figure 2, the door is in the open position, and in Figure 3 the door is fully closed having had the first panel rotated to the closed position and the second panel moved to its extended position.

25 The first panel is arranged to be slightly larger than the second panel so that an upper edge region 36 and a side edge region 37 extends beyond the second panel. As best illustrated in Figures 6 and 7, the upper edge region 36 is arranged to locate against or adjacent to an abutment surface 38 of the door frame 13, whereas as best illustrated in Figure 9 and 10, the
30 side edge region 37 is arranged to locate against a side surface 39 of the door frame 13 when the first panel is moved to its closed position. This

configuration improves the ceiling between the door 10 and the door frame 13.

The door frame 13 includes a top track 40 which on movement of the first panel 11 to the closed position is adapted to a line with the track 23 of
5 the track assembly 22. In aligning with the track 23 or movement of the first panel to the closed position, the door frame track is adapted to engage the bar 33 of the latching device 32 thereby causing it to be retracted against its spring biasing force into the housing 34. This arrangement is best illustrated in Figure 7. This thereby releases the second panel 11 to enable it to slide
10 relative to the first panel by the runner 24 being able to move within the aligned tracks 23, and 40.

The door also includes a retaining device 41 which is operable to maintain the first panel 11 in its closed position, so as to ensure that the tracks 23 and 40 remain correctly aligned. This facilitates the sliding of the
15 second panel from its retracted to its extended position.

As shown in Figure 7, in the illustrated form, the retaining device 41 includes a spring biased clip which is arranged to snap in over a tab 42 which extends from the door frame 13 when the first panel is moved to its closed position. The clip is shaped so as to be able to be cammed out of
20 engagement with the tab 42 on moving the first panel from its closed position towards its open position. The advantage of this arrangement is that the retaining device does not individually need to be released to enable the door to be opened.

An advantage of the door 10 is that it can offer substantial savings in
25 the space required to allow the door to swing between a fully opened to a fully closed position as compared to conventional hinge doors for a comparable opening size. Furthermore, the door is easy to operate. The second panel is arranged to be retained in its retracted position by the latching device thereby enabling the panels to rotate about the hinges 26, 27
30 without any inadvertent movement between the panels. Furthermore when the door is moved to its closed position it is retained in that position by the

retaining device which facilitates the correct alignment of the track of the first panel with the track located on the door frame, thereby enabling easy movement of the second panel from its retracted to its extended position.

Also on movement of the first panel to the closed position it is arranged to
5 automatically release the latching device thereby enabling the door to be moved from a fully open position to a closed position in two easy steps, the first being rotation of the first panel to the closed position the second being movement of the second panel from its retracted to its extended position.

It is to be appreciated that variations and modifications may be made
10 to the parts previously described without departing from the spirit or ambit of the invention. In particular, it is to be appreciated that the first panel may include a cavity which is adapted to receive the second panel so that the two panels are co-planar. Furthermore the coupling arrangement between the first and second panels which enables the second panel to move from its
15 retracted to its extended position can also take other forms as will be appreciated by those skilled in the art.

CLAIMS

1. A door including a first panel adapted to be rotatably mounted to a support structure, and a second panel which is connected to, and rotatable with, said first panel, the second panel being disposed generally parallel to, or
5 coplanar with, said first panel and being moveable thereto in the plane of the panels, such that the second panel is moveable relative to the first panel between a retracted position where the second panel is generally laterally adjacent to the first panel and an extended position where the second panel is spaced from the first panel in the plane of the panels.
- 10 2. A door according to claim 1, wherein each of the panels is generally rectangular having opposite ends which are spaced apart and interconnected by opposite sides, and wherein the first panel is adapted to be rotatably mounted to the support structure about an axis which extends generally in the direction of the opposite sides of said first panel, and wherein the second panel
15 is moveable relative to the first panel in a direction transverse to said axis.
3. A door according to claim 2, wherein the sides of the first panel are generally parallel to the sides of the second panel.
4. A door according to any preceding claim, further including a latching device operative to couple the first and second panels together so as to
20 maintain the second panel in its retracted position, the latching device further including a release mechanism which is operable to release the second panel so as to enable the panels to move to its extended position.
5. A door according to claim 4, wherein the release mechanism is adapted to be operatively associated with the support structure so as to automatically
25 release the second panel on rotation of the first panel to a predetermined position relative to said support structure.
6. A door according to either claim 4 or 5, wherein the latching device includes a bar which is movable between an engaged position wherein it interconnects the first and second panels to inhibit relative movement of the
30 panels, to a released position wherein the bar is remote from said second panel, the latching device including a biasing spring to bias the bar into its

engaged position.

7. A door according to any preceding claim, wherein the first panel further includes a retaining device which is operable to engage with the support structure so as to retain the first panel in a predetermined position relative to
5 said support structure.

8. A door according to claim 7, wherein the retaining device includes a spring bias clip which is operable to be released on the application of manual pressure to the first panel in a direction to rotate the door about the support structure from said predetermined position.

10 9. A door according to any preceding claim, wherein the first and second panels are interconnected by a track assembly including a track, and a runner which is captured within the track and slidable therein, and wherein the track is fixed to one of the first or second panels, and the runner is connected to the other of said first and second panels.

15 10. A door according to claim 9, further including a pair of said track assemblies disposed at opposite ends of the respective panels.

11. A door according to any one of claim 9 or 11, wherein the or each track is connected to the first panel and the or each runner is connected to the second panel.

20 12. A door assembly, including a door frame defining an opening and door, the door including a first generally planar panel which is rotatably mounted to the door frame and moveable between an open and a closed position, and a second panel which is connected to, and rotatable with, said first panel, the second panel being disposed generally parallel to, or coplanar with, said first
25 panel, and moveable thereto in the plane of the panels, such that the second panel is movable relative to the first panel between a retracted position wherein said second panel is generally laterally adjacent to the first panel, to an extended position wherein the second panel is spaced from the first panel in the direction of the plane of the panels, the door assembly being operative to
30 cover the opening defined by the door frame by movement of the first panel from its open to its closed position, and movement of the second panel from its

- 12 -

retracted to its extended position.

13. A door assembly according to claim 12, further including a latching device operative to couple the first and second panels together so as to maintain the second panel in its retracted position, the latching device further
5 including a release mechanism which is operative to release the second panel so as to enable the panels to move to its extended position, wherein the release mechanism is adapted to be operatively associated with the door frame so as to automatically release the second panel on rotation of the first panel to its closed position.

10 14. A door assembly according to claim 13, wherein the latching device includes a bar which is movable between an engaged position wherein it interconnects the first and second panels to inhibit relative movement of the panels, to a release position where the bar is remote from said second panel, the latching device including a biasing spring to bias the bar into its engaged
15 position, and wherein the bar is adapted to move from the engaged position to the released position by engagement of the bar with an abutment surface connected to, or integrally formed with, the door frame on movement of the first panel to the closed position.

15. A door assembly according to any one of claims 12 to 14, wherein the
20 door assembly further includes a retaining device which is operable to couple the first panel to the door frame so as to retain the first panel in the closed position.

16. A door assembly according to claim 15, wherein the retaining device includes a spring biasing clip which is operable to be released on the
25 application of manual pressure to the first panel to rotate the door from the closed position to its open position.

17. A door assembly according to any one claims 12 to 16, wherein the first and second panels are interconnected by a track assembly located at or adjacent an upper end of the respective panels, the track assembly including
30 a first track mounted on the first panel and a runner which is connected to the second panel and which is captured within the first track and slidable therein.

- 13 -

18. A door assembly according to claim 17, wherein a second track is connected to the door frame, and wherein on movement of the first panel to the closed position, the second track is adapted to align with the track on the first panel so as to enable the runner connected to the second panel to slide
5 between the first and second tracks.

19. A door assembly according to either claim 17 or 18 wherein the first and second panels include a second said track assembly located at a lower end of the respective panels, said second track assembly being adapted to interconnect said first and second panels and include a track, and a runner
10 which is captured within the track and slidable therein.
