Abstract

Device for holding drinks cups, drinking vessels or the like in a storage compartment of a motor vehicle. A collapsible supporting ring consists of a first half (4) and a second half (5) which are coupled to each other by means of hinges (8) and are movable from a vertical collapsed position to a horizontal position that completes the supporting ring (1). The second ring half (5) is mounted in guide rails (2) so that there is possible a downwards-rotating movement and at the same time a longitudinal movement along the guide rails in the direction of the first ring half (4). The device allows a plurality of containers to be held securely by means of an additional clamping element (10) and can be installed in relatively flat storage compartments by virtue of its low overall height.
