ABSTRACT

A multi-cluster service system, a service access method, an information configuration method, a device, and a medium. VPCs bearing service clusters are divided into a service VPC and a client VPC, a target service having different service information in the service VPC and the client VPC; the service information specifically can be provided by virtual network interface controller devices in the service VPC and the client VPC, and, by maintaining the different service information of the target service in the client VPC and the service VPC and by being capable of providing a mapping relation between service instance information of the target service, a cross-VPC service is realized.
