

ABSTRACT

An article transfer device (1), including: a machine frame (11), a lift assembly (14), a conveying platform (12) and multiple loading plates (13). The multiple loading plates are connected with the machine frame by the lift assembly, and the conveying platform is at a bottom of a machine chamber of the machine frame. Each of the multiple loading plates is provided with a first comb structure (311) including multiple first loading rods (131), and the conveying platform is provided with a second comb structure including multiple second loading rods (121) and matching the first comb structure. When the article transfer device transfers articles, the lift assembly is configured to control the multiple loading plates to move along a direction perpendicular to the conveying platform, and the first comb structures of the multiple loading plates run through a plane where the second comb structure of the conveying platform is located, such that the multiple loading plates perform article exchange with the conveying platform.
