CACHE ENABLEMENT MANAGEMENT METHOD FOR NAS AND RELATED DEVICE

ABSTRACT

A cache enablement management method for NAS and a related device are provided. The method is applied to NAS-based use cases. The method includes: At least one service is deployed in a NAS client; when the NAS client is to obtain configuration information corresponding to a first service in the at least one service, the NAS client sends a first query request corresponding to the first service to a NAS server, where the query request is used to obtain the configuration information corresponding to the first service; and then the NAS client receives first configuration information fed back by the NAS server and determines, based on the first configuration information, whether to enable a local cache function of the first service. By using the NAS server to implement differentiated management on whether to enable the local cache function, this solution meets personalized requirements of different services.
