

Abstract

[Abstract]

[Subject] To provide a compact type of equipment with less noise by which stool of a person receiving care can be processed surely without the person's unpleasant sensation regardless of stool's nature, reducing the load on the person receiving care.

[Means of solving the problems] In the processing equipment of excretory substances, the suction circulation tube 50 is led to the cooling unit 55 outside the device house box 12 from the discharge side of the suction motor 31 and cooled down by heat exchange with outer air inside the cooling unit 55, and then returned to the return box unit 27. The defecation sensor 13 comprises a sensor which detects stool's hardness to control in order to vacuum up at the setting with the higher suction power for signals of harder stool. The urination sensor 14 comprises a sensor which has two contact points to calculate a necessary suction power according to the degree of the signals and control. Moreover, the suction motor 31, cooling fan 32, and filter 33 inside the suction motor unit 24 are covered by highly rigid vibration-suppression material processed by vibration preventive material, placed on vibration preventive board, and held with suspension by the vibration preventive spring 79.
