

DIHYDROCHROMENE DERIVATIVES

TECHNICAL FIELD

[0001]

5 The present invention relates to a dihydrochromene derivative and a pharmaceutically acceptable salt thereof which is useful as a medicament, and relates to an anti-tumor agent comprising the derivative as an active ingredient.

10 BACKGROUND ART

[0002]

Conventional cancer treatments are sometimes not expected to bring in meaningful survival effects even if they can induce the regression of tumors, partly because
15 nowadays, it has been suggested that cancer stem cells (hereinafter referred to as "CSCs" as necessary) are closely involved in the persistent proliferation of malignant tumors, metastasis or recurrence of cancer, and resistance to anti-tumor agents. CSCs have been identified in almost all types
20 of major cancers in human such as breast cancer, colon cancer, lung cancer, and hematological malignancy (Non-Patent Literature 1). Also, CSCs can be greatly different in the biological features from normal cancer cells obtained from
25 anti-tumor agent that targets CSCs is expected to lead to a

new strategy for cancer treatments (Non-Patent Literature 2).

[0003]

One of the features in CSCs is the self-renewal ability
5 (Non-Patent Literature 3). Reliable methods established for
measuring the self-renewal ability of cells include, for
example, a method for measuring the sphere-forming ability
of cancer cells in non-adherent condition in the absence of
serum (Non Patent Literature 4).

10 [0004]

There has been no literature disclosing that the present
compounds of formula (1) shown below can exhibit anticancer
action or inhibitory action of the sphere-forming ability of
cancer cells until now.

SUMMARY OF INVENTION

[0006]

5 (Technical Problem)

An object of the present invention is to provide useful compounds as a novel anti-tumor agent that targets CSCs which are thought to be closely involved in the persistent proliferation of malignant tumor, metastasis or recurrence

10

To a solution of 1-tert-butyl 4-methyl piperidine-1,4-dicarboxylate (69.0 g) in tetrahydrofuran (700 mL) was added dropwise 1 mol/L sodium bis(trimethylsilyl)amide (326 mL) at -78°C, and the reaction mixture was stirred at the temperature for an hour. The reaction mixture was warmed to -20°C, and stirred at the temperature for an hour. To the reaction mixture was added dropwise 1-bromo-3-methyl-2-butene (42.6 mL) at -78°C. Test 1: Inhibition test for sphere formation assay of cancer cells

Reliable methods established for measuring the self-renewal ability of cells which is one of the CSC's properties include a method for measuring the sphere-forming ability of cancer cells in non-adherent condition in the absence of serum (Cancer Res 65, 5506-5511 (2005)). HT-29 cells were available from American Type Culture Collection (ATCC). HT-

29 cells were cultured at 37°C under 5 % CO₂ using the McCoy's 5a medium containing 10 % fetal bovine serum (FBS) and 1 % penicillin/streptomycin. HT-29 cells were seeded in a 384 Well Black Clear Bottom Ultra-Low Attachment Microplate (Corning Cat. No.3827) in an amount of 350-800 cells/well using the DMEM/F12 medium containing 2 % B27 supplement (GIBCO), 20 ng/mL epidermal growth factor (EGF) (peprotech), 10 ng/mL basic fibroblast growth factor (bFGF) (peprotech), 5 µg/mL insulin (Sigma), and 1% penicillin/streptomycin. Each test compound was added into each well to adjust the final concentration of DMSO to 0.1 %, and the cells were cultured for 4 days. The number of viable cells in each well was then measured with CellTiter-Glo™ Luminescent Cell Viability Assay (Promega) to calculate the concentration of each test compound for 50 % inhibition of cell proliferation (Sphere IC₅₀ value; µmol/L).

[0189]

The experiment of Test 1 was performed for each compound of each Example. The concentration of each test compound for 50 % inhibition of cell proliferation (Sphere IC₅₀ value; µmol/L) is shown in the following Table.

Test 2: Test for evaluating hERG inhibition

To a cultured CHO cell strain which stably expresses hERG was added each test compound to adjust the final concentration of DMSO to 0.0135 to 0.5 %. The hERG current

was measured with QPatch HT (Sophion Inc.), and the concentration at which 50 % of the hERG current was inhibited by each test compound (IC₅₀ value; μ M) was calculated.

[0192]

5 The compounds of Examples were tested according to Test 2. And, the hERG/HT-29 was calculated by dividing the compound concentration obtained in Test 2 (50 % of the hERG current is inhibited) by the compound concentration obtained in Test 1 (50 % of the proliferation of HT-29 cells is inhibited). The results are shown in the following table.
