

## DESCRIPTION

### Title of Invention

POLISHING HEAD AND POLISHING APPARATUS

### 5 Technical Field

[0001] The present invention relates to a polishing head for pressing a polishing tool against a substrate, such as a wafer. Further, the present invention relates to a polishing apparatus for polishing a substrate with such a polishing head.

### Background Art

10 [0002] Devices, such as memory circuits, logic circuits and image sensors (e.g., CMOS sensors) are becoming more highly integrated these days. In a process for forming such devices on a substrate, such as a wafer, foreign matter, such as fine particles, dust, and unwanted film, may adhere to the substrate. Foreign matter adhering to the substrate can cause defects, such as a manufacturing failure and breakage of a device. Therefore, in  
15 order to enhance the reliability of the device, it is necessary to remove the foreign matter on the substrate.

[0003] In order to remove the foreign matter on the substrate, such as a wafer, there is a polishing apparatus configured to polish the substrate using a polishing tool. One type of such a polishing apparatus is configured to polish the substrate by rubbing a polishing tool  
20 against the substrate. The polishing apparatus presses the polishing tool against the substrate by a polishing head to polish the substrate.

### Summary of Invention

#### Technical Problem

[0005] An example of the polishing apparatus includes a polishing apparatus configured to

polish a substrate by pressing a polishing tool against the substrate by a polishing head, while rotating the substrate and feeding the polishing tool, such as a polishing tape, in one direction. The polishing head of this polishing apparatus includes a pressing tool configured to press the polishing tool against the substrate. However, due to a machining accuracy limit of the pressing tool, a contact surface of the pressing tool being in contact with the polishing tool may have irregularities, and a smooth contact surface may not be obtained. The contact surface that is not smooth may cause a variation in pressing force of the polishing tool against the substrate and may cause a region where the polishing tool does not contact the substrate. As a result, a desired polishing performance may not be obtained.

[0006] Thus, the present invention provides a polishing head capable of pressing a polishing tool against a substrate with a uniform force. Further, the present invention provides a polishing apparatus including such a polishing head.

#### **Solution to Problem**

[0007] In an embodiment, there is provided a polishing head for polishing a substrate, comprising: an annular elastic member configured to press a polishing tool against the substrate; and a pressing-tool body having a pressing surface configured to press the polishing tool against the substrate via the elastic member, wherein the pressing surface has a first fitting groove in which a first portion of the elastic member fits, the first portion protrudes from the pressing surface, the elastic member is put on the pressing-tool body with the elastic member elastically deformed, and the polishing head is configured to press the polishing tool against the substrate by the first portion.

[0008] In an embodiment, the elastic member is detachably put on the pressing-tool body.

In an embodiment, the elastic member has a circular cross section.

In an embodiment, the elastic member is covered with a coating layer containing a fluororesin.

In an embodiment, the pressing-tool body further has a tapered surface extending obliquely from the pressing surface.

In an embodiment, a side surface of the pressing-tool body has a second fitting

groove in which a second portion of the elastic member fits.

In an embodiment, the pressing-tool body has a protrusion on a side surface of the pressing-tool body, and the protrusion supports the elastic member.

5 In an embodiment, the first fitting groove comprises a plurality of first fitting grooves located away from each other, and the first portion comprises a plurality of first portions fitting in the plurality of first fitting grooves, respectively.

In an embodiment, the first fitting groove has an arc shape having the same curvature as a curvature of the substrate.

[0009] In an embodiment, there is provided a polishing apparatus comprising: a substrate  
10 holder configured to hold a substrate; and the above-mentioned polishing head configured to press a polishing tool against the substrate to polish the substrate.

#### **Advantageous Effects of Invention**

[0010] According to the present invention, the polishing head includes the annular elastic member for pressing the polishing tool against the substrate. Tension is applied to the  
15 elastic member, and the elastic member is put on the pressing-tool body with the elastic member elastically deformed, while the elastic member fits in the fitting groove. As a result, a contact surface of the elastic member with the polishing tool is stretched and smoothed. Therefore, the polishing head can press the polishing tool against the substrate with a uniform force.

### **Description of Embodiments**

[0012] Embodiments of the present invention will now be described with reference to the drawings.

15 FIG. 1 is a perspective view showing a polishing head configured to polish a wafer by pressing a polishing tape, which is an example of a polishing tool, against a surface of the wafer, which is an example of a substrate. FIG. 2 is a diagram showing the polishing head shown in FIG. 1 as viewed from a direction indicated by an arrow A in FIG. 1. FIG. 3 is a plan view of the polishing head. FIG. 4 is a cross-sectional view taken along a line B-B in  
20 FIG. 3. As shown in FIG. 4, a polishing head 10 of the present embodiment is disposed below a wafer W and a polishing tape 3. In FIGS. 1 and 2, the wafer W and the polishing tape 3 are not depicted.

[0013] As shown in FIG. 4, the polishing head 10 includes a pressing tool 12 configured to press the polishing tape 3 against the wafer W, a movable shaft 15 coupled to the pressing  
25 tool 12, a housing 18 configured to house the movable shaft 15 therein, and a partition membrane (or diaphragm) 25 configured to form a pressure chamber 20 between an end portion of the movable shaft 15 and the housing 18. The pressing tool 12 includes an annular elastic member 40 configured to press the polishing tape 3 against the wafer W, and

a pressing-tool body 43 configured to support the elastic member 40.

[0014] As shown in FIGS. 1 to 4, the pressing-tool body 43 has a pressing surface 44 configured to press the polishing tape 3 against the wafer W via the elastic member 40. The pressing surface 44 has a fitting groove 45 in which the elastic member 40 fits. The elastic member 40 is put on the pressing-tool body 43 with the elastic member 40 elastically deformed, while the elastic member 40 fits in the fitting groove 45. The elastic member 40 has a portion 41 fitting in the fitting groove 45. A thickness of the elastic member 40 is larger than a depth of the fitting groove 45, and thus the portion 41 of the elastic member 40 protrudes from the pressing surface 44.

[0015] The movable shaft 15 is movable in an axial direction thereof in the housing 18, and the movable shaft 15 can elevate the pressing tool 12. The pressing surface 44 faces a back surface of the polishing tape 3. When the movable shaft 15 elevates the pressing tool 12, the portion 41 of the elastic member 40 is brought into contact with the back surface of the polishing tape 3. During polishing of the wafer W, the elastic member 40 presses a polishing surface of the polishing tape 3 against a lower surface of the wafer W. The back surface of the polishing tape 3 is supported by the elastic member 40. The back surface of the polishing tape 3 is an opposite side of the polishing tape 3 from the polishing surface having abrasive grains. During the polishing of the wafer W, the polishing tape 3 is advanced with a predetermined speed. As shown in FIG. 3, the portion 41 of the elastic member 40 and the fitting groove 45 are inclined obliquely with respect to an advancing direction of the polishing tape 3. Angles of the portion 41 of the elastic member 40 and the fitting groove 45 with respect to the advancing direction of the polishing tape 3 are not limited to the embodiment shown in FIG. 3.

[0016] The elastic member 40 is made of a flexible material. Examples of the material constituting the elastic member 40 include rubbers, such as fluoro-rubber, silicone rubber, ethylene propylene diene rubber, or the like. A cross section of the elastic member 40 has a circular shape. The elastic member 40 may be an O-ring. A diameter of the elastic member 40 may preferably be in a range of 1.0 mm to 10 mm.

[0017] The elastic member 40 is detachably put on the pressing-tool body 43. FIG. 5 is a diagram showing the pressing-tool body 43 from which the elastic member 40 has been removed. The fitting groove 45 extends straight across the pressing surface 44, and a cross section of the fitting groove 45 has an arc shape. The elastic member 40 is secured to the pressing-tool body 43 by putting the elastic member 40 on the pressing-tool body 43 while fitting the elastic member 40 in the fitting groove 45 and stretching the elastic member 40.

[0018] When the elastic member 40 is supported on the pressing-tool body 43 with the elastic member 40 elastically deformed, a tension is applied to the elastic member 40. A radius of curvature of the cross section of the fitting groove 45 is smaller than a radius of the cross section of the elastic member 40 when the elastic member 40 is not elastically deformed. Therefore, the portion 41 of the elastic member 40 is in tight contact with a surface of the fitting groove 45 and is fixed in the fitting groove 45. As a result, the elastic member 40 is secured stably to the pressing-tool body 43.

[0019] In one embodiment, the cross-sectional shape of the elastic member 40 may be a polygon, such as a quadrangle or a hexagon, or a shape having an arc shape in a part of the cross section. The cross-sectional shape of the fitting groove 45 is not limited to the arc shape. In one embodiment, the cross section of the fitting groove 45 may have a rectangular shape.

[0020] When the elastic member 40 is held on the pressing-tool body 43, the elastic member 40 is stretched, so that a contact surface of the elastic member 40, which is to be brought into contact with the polishing tape 3, is stretched and becomes smooth. As a result, the polishing head 10 can press the polishing tape 3 against the wafer W with a uniform force. Furthermore, since the elastic member 40 is in tight contact with the surface of the fitting groove 45 and is secured in the fitting groove 45, the position of the elastic member 40 relative to the pressing-tool body 43 is not changed during the polishing of the wafer W.

[0021] The elastic member 40 is not fixed to the pressing-tool body 43 with a fixing tool, such as a screw, but is simply put on the pressing-tool body 43. Therefore, when the elastic

member 40 is deteriorated by the polishing, only the elastic member 40 can be easily replaced. As a result, the replacement work for the deteriorated member can be performed easily, and a cost of part replacement can be reduced.

[0022] Even if the portion 41 of the elastic member 40 is deteriorated by the polishing, one  
5 elastic member 40 can be reused multiple times by replacing a portion of the elastic member 40 fitting in the fitting groove 45 from one to another within the same elastic member 40. Therefore, a service life of the elastic member 40 can be extended, and the cost of part replacement can be further reduced.

[0023] As shown in FIGS. 1 to 3, the entire elastic member 40 surrounds the pressing-tool  
10 body 43. The elastic member 40 is put only on the pressing surface 44 and side surfaces of the pressing-tool body 43, and the elastic member 40 does not present on a back side of the pressing-tool body 43. Therefore, an operator can easily remove only the elastic member 40 without removing the pressing-tool body 43 from the polishing head 10. In one embodiment, the elastic member 40 may be put on an opposite side (back side) of the  
15 pressing-tool body 43 from the pressing surface 44, but the configuration, in which the elastic member 40 is put on the pressing-tool body 43 without putting on the back side of the pressing-tool body 43, can make the replacement of the elastic member 40 easier.

[0024] The pressing-tool body 43 of the present embodiment has a fitting groove 51  
20 formed in a side surface of the pressing-tool body 43, and the elastic member 40 fits in the fitting groove 51. Specifically, the pressing-tool body 43 has the fitting groove 51 in a side surface 47. The fitting groove 51 extends straight across the side surface 47, and a cross section of the fitting groove 51 has an arc shape. Details of the fitting groove 51, which will not be particularly described, are the same as those of the above-described fitting groove 45, and duplicated descriptions will be omitted. The elastic member 40 of the present  
25 embodiment is put on the pressing-tool body 43 with the elastic member 40 elastically deformed, while the elastic member 40 fits in the fitting groove 51. The elastic member 40 has a portion 52 fitting in the fitting groove 51. The portion 52 of the elastic member 40 is in tight contact with a surface of the fitting groove 51 and is secured in the fitting groove 51.

As a result, the elastic member 40 is secured more stably to the pressing-tool body 43.

[0025] The pressing-tool body 43 of the present embodiment has protrusions 54 and 55 on side surfaces of the pressing-tool body 43. Specifically, the protrusion 54 is fixed to a side surface 48, and the protrusion 55 is fixed to a side surface 49 which is an opposite side from the side surface 48. In the present embodiment, the elastic member 40 is put on the protrusions 54 and 55 with the elastic member 40 elastically deformed, and the elastic member 40 is further supported by the protrusions 54 and 55. As a result, the elastic member 40 is secured more stably to the pressing-tool body 43. In one embodiment, the protrusion 54 may be integrally formed with the side surface 48, and the protrusion 55 may be integrally formed with the side surface 49.

[0026] In one embodiment, the side surface 47 of the pressing-tool body 43 may not have the fitting groove 51. Even if the side surface 47 does not have the fitting groove 51, the elastic member 40 can be secured stably to the pressing-tool body 43 when the elastic member 40 is put on the protrusions 54 and 55. Further, in one embodiment, a protrusion capable of supporting the elastic member 40 may be fixed to the side surface 47. In this case, the side surface 47 may not have the fitting groove 51.

[0027] In one embodiment, the pressing-tool body 43 may include only one of the protrusions 54 and 55. Further, in one embodiment, the pressing-tool body 43 may have a fitting groove, in which the elastic member 40 fits, in the side surface 49 and/or the side surface 48. In this case, the pressing-tool body 43 may not have the protrusion 54 and/or the protrusion 55. Even if the pressing-tool body 43 does not have the protrusion 54 and/or the protrusion 55, the elastic member 40 can be secured stably to the pressing-tool body 43 when the elastic member 40 fits in the fitting groove(s) formed in the side surface 49 and/or the side surface 48.

[0028] As shown in FIG. 4, the movable shaft 15 is movable in the axial direction thereof in the housing 18. In this embodiment, the movable shaft 15 is constituted of a ball spline shaft. A ball spline nut 30 is disposed in the housing 18, so that the movable shaft 15 is supported movably in a vertical direction by the ball spline nut 30. In one embodiment, the

movable shaft 15 may be movably supported on an inner surface of the housing 18.

[0029] The housing 18 includes a housing body 18A forming a space for housing the movable shaft 15 therein, and a lid 18B configured to close the space. The lid 18B is detachably fixed to the housing body 18A by screws 31. The partition membrane 25 is in  
5 contact with the end portion (lower end) of the movable shaft 15, and an edge of the partition membrane 25 is sandwiched between the housing body 18A and the lid 18B. The partition membrane 25 is only in contact with the movable shaft 15 and is not fixed to the movable shaft 15.

[0030] The pressure chamber 20 is formed by the partition membrane 25 and the inner  
10 surface of the housing 18. More specifically, the pressure chamber 20 is formed by the partition membrane 25 and an inner surface of the lid 18B. A compressed-gas flow passage 33 communicating with the pressure chamber 20 is formed in the lid 18B of the housing 18. The compressed-gas flow passage 33 is coupled to a compressed-gas supply source 38 via a pressure regulator 36 and a switching valve 35. The switching valve 35 is a valve  
15 configured to selectively communicate the compressed-gas flow passage 33 with the compressed-gas supply source 38 or the atmosphere. A three-way valve can be used as the switching valve 35. A pump, or a compressed-gas supply line as a utility equipment pre-installed in a factory can be used as the compressed-gas supply source 38.

[0031] The partition membrane 25 is made of a flexible material. Examples of the  
20 material constituting the partition membrane 25 include chloroprene rubber, fluoro-rubber, and silicone rubber. Chloroprene rubber having high bending fatigue resistance is preferably used.

[0032] When the wafer W is to be polished, the switching valve 35 is operated to allow the compressed-gas flow passage 33 to communicate with the compressed-gas supply source 38.  
25 Compressed gas, such as compressed air, is supplied from the compressed-gas supply source 38 through the compressed-gas flow passage 33 into the pressure chamber 20. A pressure of the compressed gas in the pressure chamber 20 is controlled by the pressure regulator 36. The pressure of the compressed gas in the pressure chamber 20 acts on the end portion

(lower end) of the movable shaft 15 through the partition membrane 25, and elevates the movable shaft 15 and the pressing tool 12. FIG. 6 is a diagram showing the movable shaft 15 and the pressing tool 12 when elevated. The elastic member 40 of the pressing tool 12 can press the polishing tape 3 against the lower surface of the wafer W.

5 [0033] As shown in FIG. 6, when the elastic member 40 presses the polishing tape 3 against the lower surface of the wafer W, the polishing tape 3 bends in a direction toward the pressing-tool body 43. Thus, in order to prevent the polishing tape 3 from coming into contact with the pressing-tool body 43, the pressing-tool body 43 of the present embodiment further has a plurality of tapered surfaces 56a and 56b extending obliquely from the pressing  
10 surface 44. More specifically, the tapered surface 56a extends obliquely downward from the pressing surface 44 and is coupled to the side surface 47. The other tapered surface 56b extends obliquely downward from the pressing surface 44 and is coupled to a side surface 50 which is an opposite side from the side surface 47. These tapered surfaces 56a and 56b can prevent the polishing tape 3 from contacting the pressing-tool body 43 when the elastic  
15 member 40 presses the polishing tape 3 against the lower surface of the wafer W.

[0034] When the polishing of the wafer W is to be terminated, the switching valve 35 is operated to allow the compressed-gas flow passage 33 to communicate with the atmosphere. The pressure chamber 20 is ventilated to the atmosphere, and as a result, the movable shaft 15 and the pressing tool 12 are lowered to a retracted position shown in FIG. 4 due to weight  
20 of the movable shaft 15 and tension of the polishing tape 3.

[0035] At least a part of a distance sensor 65 configured to measure a movement distance of the movable shaft 15 relative to the housing 18 is disposed in the pressure chamber 20. The entire distance sensor 65 may be disposed in the pressure chamber 20. The distance sensor 65 of the present embodiment is a non-contact optical distance sensor. A distal end  
25 of the distance sensor 65 is oriented toward the end portion of the movable shaft 15.

[0036] As shown in FIG. 6, the pressing tool 12 is coupled to an upper end of the movable shaft 15 via a universal joint 67. The universal joint 67 is disposed between the movable shaft 15 and the pressing tool 12, and is housed inside the pressing tool 12. Such an

arrangement can reduce moment caused by a reaction force applied from the wafer W to the pressing tool 12 when the polishing tape 3 is in contact with the wafer W. As a result, a posture of the polishing head 10 can be stable.

[0037] The universal joint 67 allows the pressing tool 12 to tilt in all directions with respect to the movable shaft 15. Therefore, when the pressing tool 12 presses the polishing tape 3 against the surface of the wafer W, the pressing tool 12 automatically becomes parallel to the surface of the wafer W. The universal joint 67 configured to tiltably support the pressing tool 12 allows the polishing tape 3 to be pressed uniformly against the surface of the wafer W.

10 [0038] As shown in FIG. 4, a skirt 71 is fixed to the pressing tool 12. The skirt 71 extends downward from the pressing tool 12 and surrounds an upper portion of the housing 18. In the present embodiment, the skirt 71 has a cylindrical shape, but the skirt 71 may have another shape as long as it can surround the upper portion of the housing 18. The skirt 71 can prevent liquid, such as pure water, used for the polishing of the wafer W from  
15 entering the universal joint 67 and the housing 18.

[0039] Since the polishing head 10 having the above-described configuration is compact as a whole, the polishing head 10 can be arranged below the wafer W. Further, a plurality of polishing heads 10 can be arranged below the wafer W.

[0040] FIG. 7 is a perspective view showing another embodiment of the polishing head 10. FIG. 8 is a diagram showing the polishing head 10 shown in FIG. 7 as viewed from a direction indicated by an arrow C in FIG. 7. FIG. 9 is a plan view of the polishing head 10 shown in FIG. 7. FIG. 10 is a cross-sectional view taken along a line D-D in FIG. 9. FIG. 11 is a diagram showing the pressing-tool body 43 shown in FIG. 7 from which the elastic member 40 has been removed. FIG. 10 shows the elastic member 40 when pressing the  
25 polishing tape 3 against the lower surface of the wafer W. Details of the present embodiment, which will not be particularly described, are the same as those of the embodiments described with reference to FIGS. 1 to 6, and duplicated descriptions will be omitted.

[0041] The pressing-tool body 43 of the present embodiment has a plurality of fitting grooves 45 in the pressing surface 44. Specifically, the pressing-tool body 43 has two fitting grooves 45 in the pressing surface 44. The two fitting grooves 45 are located away from each other, and are inclined obliquely with respect to the advancing direction of the polishing tape 3 when the pressing-tool body 43 is viewed from above. In this embodiment, the two fitting grooves 45 are arranged symmetrically about a center line L1 (see FIG. 9) of the pressing surface 44 located between the side surface 47 and the side surface 50. In one embodiment, the two fitting grooves 45 may be not arranged symmetrically about the center line L1 as long as the fitting grooves 45 are inclined obliquely with respect to the advancing direction of the polishing tape 3. The pressing-tool body 43 includes a protrusion 54 fixed to the side surface 48 of the pressing-tool body 43, and a plurality of protrusions 55 fixed to the side surface 49. When the pressing-tool body 43 is viewed from above, the protrusion 54 is arranged on the center line L1. The two protrusions 55 are located away from each other and are arranged at the same height. When the pressing-tool body 43 is viewed from above, the two protrusions 55 are arranged symmetrically about the center line L1. The elastic member 40 is put on the protrusion 54 and the protrusions 55 with the elastic member 40 elastically deformed, while the elastic member 40 fits in the two fitting grooves 45. With the above-described arrangement of the protrusion 54 and the protrusions 55, the elastic member 40 can be secured stably to the pressing-tool body 43. In one embodiment, the protrusion 54 may not be arranged on the center line L1, and the two protrusions 55 may not be arranged symmetrically about the center line L1, as long as the protrusion 54 and the protrusions 55 are arranged such that the elastic member 40 can be stably secured to the pressing-tool body 43.

[0042] The elastic member 40 has two portions 41 fitting in the two fitting grooves 45, respectively. These two portions 41 protrude from the pressing surface 44. The two portions 41 of the elastic member 40 can increase a contact area between the polishing tape 3 and the elastic member 40, and can increase a polishing rate of the wafer W. According to the configuration of the present embodiment described above, the two portions 41 can be

configured by the single elastic member 40. As a result, the polishing rate of the wafer W can be increased with a low-cost configuration.

[0043] In one embodiment, the number of protrusions 55 may not be two. For example, the pressing-tool body 43 may include a single laterally-elongated protrusion 55 or may  
5 include three or more protrusions 55. Further, in one embodiment, the plurality of protrusions 55 may not be arranged at the same height as long as the elastic member 40 can be stably secured to the pressing-tool body 43.

[0044] FIG. 12 is a cross-sectional view showing still another embodiment of the polishing head 10. Details of the present embodiment, which will not be particularly described, are  
10 the same as those of the embodiments described with reference to FIGS. 1 to 6, and duplicated descriptions will be omitted. The elastic member 40 of the present embodiment is covered with a coating layer 58 containing a fluororesin. The coating layer 58 covering the elastic member 40 can reduce a sliding resistance between the elastic member 40 and the back surface of the polishing tape 3 during the polishing of the wafer W. As a result,  
15 during the polishing of the wafer W, the polishing tape 3 can be advanced smoothly, and a force required to advance the polishing tape 3 can be reduced. The polishing head 10 of the present embodiment can also be applied to the embodiments described with reference to FIGS. 7 to 11.

[0045] FIG. 13 is a diagram showing an embodiment of a polishing apparatus including  
20 the polishing head 10. A polishing apparatus 100 shown in FIG. 13 includes a substrate holder 110 configured to hold a wafer W, which is an example of a substrate, and rotate the wafer W about its own axis, the above-described polishing head 10 configured to bring a polishing tape 3 as a polishing tool into contact with a first surface 1 of the wafer W held by the substrate holder 110 to polish the first surface 1 of the wafer W, and a polishing-tape  
25 supply mechanism 141 configured to supply the polishing tape 3 to the polishing head 10.

[0046] The substrate holder 110 includes a plurality of rollers 111 which can contact a periphery of the wafer W, and a roller-rotating mechanism (not shown) configured to rotate the plurality of rollers 111 about their respective own axes. The polishing head 10 is

arranged below the wafer W held by the substrate holder 110. A part of the substrate holder 110 is not shown in FIG. 13. The substrate holder 110 of the present embodiment includes four rollers 111 (two of which are not shown).

[0047] In the present embodiment, the first surface 1 of the wafer W is a back surface of the wafer W on which no device is formed or no device is to be formed, i.e., a non-device surface. A second surface 2 of the wafer W opposite to the first surface 1 is a surface on which devices are formed or devices are to be formed, i.e., a device surface. In this embodiment, the wafer W is held by the substrate holder 110 horizontally with the first surface 1 facing downward.

[0048] The roller-rotating mechanism is configured to rotate the four rollers 111 with the same speed in the same direction. During polishing of the first surface 1 of the wafer W, the periphery of the wafer W is held by the rollers 111. The wafer W is held horizontally, and is rotated about its own axis by the rotations of the rollers 111. During the polishing of the first surface 1 of the wafer W, the four rollers 111 rotate about their respective own axes, but the positions of the rollers 111 themselves are stationary.

[0049] As shown in FIG. 13, a rinsing-liquid supply nozzle 127 configured to supply a rinsing liquid (e.g., pure water or an alkaline chemical solution) to the first surface 1 of the wafer W is disposed below the wafer W held by the substrate holder 110. The rinsing-liquid supply nozzle 127 is coupled to a not-shown rinsing-liquid supply source. The rinsing-liquid supply nozzle 127 is oriented toward the center O1 of the first surface 1 of the wafer W. The rinsing liquid is supplied from the rinsing-liquid supply nozzle 127 to the first surface 1 of the wafer W, and spreads over the first surface 1 of the wafer W due to centrifugal force. The rinsing liquid flows on the first surface 1 of the wafer W outward in a radial direction, whereby polishing debris can be removed from the first surface 1 of the wafer W.

[0050] A protecting-liquid supply nozzle 128 configured to supply a protecting liquid (e.g., pure water) onto the second surface 2 of the wafer W is disposed above the wafer W held by the substrate holder 110. The protecting-liquid supply nozzle 128 is coupled to a not-

shown protecting-liquid supply source. The protecting-liquid supply nozzle 128 is oriented toward the center of the second surface 2 of the wafer W. The protecting liquid is supplied from the protecting-liquid supply nozzle 128 to the center of the second surface 2 of the wafer W, and spreads over the second surface 2 of the wafer W due to the centrifugal force.

5 The protecting liquid prevents the rinsing liquid containing the polishing debris and foreign matter generated by the polishing of the wafer W from contacting the second surface 2 of the wafer W and adhering to the second surface of the wafer W. As a result, the second surface 2 of the wafer W can be kept clean.

[0051] The polishing head 10 is supported by a support member 131, and the support  
10 member 131 is fixed to a movable plate 120. Therefore, the entire polishing head 10 can be moved together with the movable plate 120. The support member 131 has a not-shown through-hole, and the polishing tape 3 extends through the through-hole.

[0052] The polishing-tape supply mechanism 141 includes a tape feeding reel 143 configured to supply the polishing tape 3 and a tape take-up reel 144 configured to collect  
15 the polishing tape 3. The tape feeding reel 143 and the tape take-up reel 144 are coupled to tension motors 143a and 144a, respectively. These tension motors 143a and 144a are fixed to a reel base 142 and are configured to apply predetermined torques to the tape feeding reel 143 and the tape take-up reel 144 to thereby apply a predetermined tension to the polishing tape 3. The reel base 142 is fixed to the movable plate 120, so that the entire polishing-tape  
20 supply mechanism 141 can move together with the movable plate 120.

[0053] A tape advancing device 146 configured to advance the polishing tape 3 in a longitudinal direction thereof is provided between the tape feeding reel 143 and the tape take-up reel 144. The tape advancing device 146 includes a tape advancing roller 148 configured to advance the polishing tape 3, a nip roller 149 configured to press the polishing  
25 tape 3 against the tape advancing roller 148, and a tape advancing motor 147 configured to rotate the tape advancing roller 148. The polishing tape 3 is sandwiched between the nip roller 149 and the tape advancing roller 148. When the tape advancing motor 147 rotates the tape advancing roller 148 in a direction indicated by an arrow in FIG. 13, the polishing

tape 3 is advanced or fed from the tape feeding reel 143 to the tape take-up reel 144 via the pressing tool 12 of the polishing head 10. An advancing speed of the polishing tape 3 can be changed by changing a rotation speed of the tape advancing motor 147. In one embodiment, the direction in which the polishing tape 3 is advanced may be opposite to the direction indicated by arrows in FIG. 13 (an arrangement of the tape feeding reel 143 and the tape take-up reel 144 may be interchanged). Also in this case, the tape advancing device 146 is disposed at the tape take-up reel 144 side. The polishing tape 3 is supplied to the pressing tool 12 such that a polishing surface 3a of the polishing tape 3 faces the first surface 1 of the wafer W.

[0054] The polishing apparatus 100 further includes a plurality of guide rollers 153a, 153b, 153c, and 153d configured to support the polishing tape 3. The polishing tape 3 is guided so as to surround the polishing head 10 by these guide rollers 153a, 153b, 153c, and 153d. The polishing head 10 polishes the first surface 1 of the wafer W by pressing the polishing tape 3 from the back side thereof against the first surface 1 of the wafer W with the pressing tool 12. The guide rollers 153b and 153c arranged at an upper portion of the polishing head 10 guide the polishing tape 3 such that the polishing tape 3 advances in a direction parallel to the first surface 1 of the wafer W.

[0055] The tape advancing device 146 and the guide rollers 153a, 153b, 153c, and 153d are fixed to a not-shown holding member, which is fixed to the movable plate 120.

[0056] In order to bring the polishing tape 3 into contact with a region ranging from the center O1 to an outermost portion of the first surface 1 of the wafer W, the polishing apparatus 100 of the present embodiment includes a polishing-head moving mechanism 191 configured to translate the polishing head 10 relative to the substrate holder 110. The polishing-head moving mechanism 191 is configured to move the polishing head 10 between the center O1 of the first surface 1 of the wafer W and the outermost portion of the first surface 1.

[0057] A plurality of linear-motion guides 195 are fixed to a lower surface of the movable plate 120, and the movable plate 120 is supported by the plurality of linear-motion guides

195. The plurality of linear-motion guides 195 are disposed on a mounting surface 197. The movable plate 120 is moved by the polishing-head moving mechanism 191 and the linear-motion guide 195 restricts the movement of the movable plate 120 to a linear motion in the radial direction of the wafer W.

5 [0058] The polishing-head moving mechanism 191 includes a ball-screw mechanism 193 and a motor 194 configured to drive the ball-screw mechanism 193. A servo motor can be used as the motor 194. The movable plate 120 is coupled to a screw shaft 193b of the ball-screw mechanism 193. When the polishing-head moving mechanism 191 operates, the polishing head 10, the polishing-tape supply mechanism 141, the tape advancing device 146,  
10 and the guide rollers 153a, 153b, 153c, and 153d are moved in the radial direction of the wafer W relative to the substrate holder 110.

[0059] During the polishing of the wafer W, the polishing-head moving mechanism 191 moves the polishing head 10 between the center O1 of the first surface 1 of the wafer W and the outermost portion of the first surface 1. The polishing apparatus 100 further includes an  
15 operation controller 180 configured to control operations of each component of the polishing apparatus 100. The polishing-head moving mechanism 191 is electrically coupled to the operation controller 180, so that operations of the polishing-head moving mechanism 191 are controlled by the operation controller 180. When the polishing-head moving mechanism 191 operates, the polishing head 10, the polishing-tape supply mechanism 141, the tape  
20 advancing device 146, and the guide rollers 153a, 153b, 153c, and 153d are moved together.

[0060] During the polishing of the wafer W, the wafer W is rotated by the rollers 111. All the rollers 111 rotate about their own axes, but the positions of these rollers 111 are fixed. Therefore, even if the polishing head 10 is moved from the center side of the wafer W to the outer side of the wafer W by the polishing-head moving mechanism 191, the rollers 111 do  
25 not contact the polishing head 10. As a result, the polishing tape 3 can polish the entire first surface 1 including the outermost portion of the wafer W.

[0061] FIG. 14 is a plan view showing an arrangement of the polishing head 10. As shown in FIG. 14, the portion 41 of the elastic member 40 fitting in the fitting groove 45 is

shorter than a radius of the wafer W. The portion 41 of the elastic member 40 and the fitting groove 45 extend obliquely with respect to the advancing direction (indicated by an arrow E) of the polishing tape 3. In this embodiment, the advancing direction E of the polishing tape 3 coincides with the longitudinal direction of the polishing tape 3. Since the portion 41 of the elastic member 40 fitting in the fitting groove 45 is inclined obliquely with respect to the advancing direction E of the polishing tape 3 (i.e., the longitudinal direction of the polishing tape 3), an unused polishing tape 3 can be brought into contact with the wafer W even at the downstream side (in the case of this embodiment, an outer peripheral side of the wafer W) of the advancing direction E of the polishing tape 3. As a result, the polishing rate can be prevented from decreasing due to the use of the polishing tape 3 deteriorated by the polishing. In one embodiment, the portion 41 of the elastic member 40 fitting in the fitting groove 45 may be longer than the radius of the wafer W. Further, in one embodiment, the portion 41 of the elastic member 40 fitting in the fitting groove 45 may be perpendicular to the advancing direction E of the polishing tape 3.

[0062] The operations of the polishing apparatus 100 of this embodiment will now be described. The operations of the polishing apparatus 100 described below are controlled by the operation controller 180 shown in FIG. 13. The operation controller 180 is electrically coupled to the substrate holder 110, the polishing head 10, the polishing-tape supply mechanism 141, the tape advancing device 146, and the polishing-head moving mechanism 191. The operations of the substrate holder 110, the rinsing-liquid supply nozzle 127, the protecting-liquid supply nozzle 128, the polishing head 10, the polishing-tape supply mechanism 141, the tape advancing device 146, and the polishing-head moving mechanism 191 are controlled by the operation controller 180.

[0063] The operation controller 180 is composed of at least one computer. The operation controller 180 includes a memory 180a and an arithmetic device 180b. The arithmetic device 180b includes a CPU (central processing unit), a GPU (graphic processing unit), etc. configured to perform arithmetic operations according to instructions contained in programs stored in the memory 180a. The memory 180a includes a main memory (e.g., a random-

access memory) to which the arithmetic device 180b is accessible, and an auxiliary memory (e.g., a hard disk drive or a solid state drive) storing data and the programs therein.

[0064] The wafer W to be polished is held by the rollers 111 of the substrate holder 110 with the first surface 1 facing downward, and is further rotated about the axis of the wafer W.

5 Specifically, the substrate holder 110 rotates the wafer W by rotating the plurality of rollers 111 about their own axes while the plurality of rollers 111 are in contact with the periphery of the wafer W with the first surface 1 of the wafer W facing downward. Next, the rinsing liquid is supplied from the rinsing-liquid supply nozzle 127 to the first surface 1 of the wafer W, and the protecting liquid is supplied from the protecting-liquid supply nozzle 128 onto  
10 the second surface 2 of the wafer W. The rinsing liquid flows radially outward on the first surface 1 of the wafer W, and the protective liquid spreads over the entire second surface 2 of the wafer W due to the centrifugal force.

[0065] The polishing-head moving mechanism 191 moves the polishing head 10 to a position below the center O1 of the first surface 1 of the wafer W. The operation controller  
15 180 operates the polishing-tape supply mechanism 141 and the tape advancing device 146 to advance the polishing tape 3 in the longitudinal direction thereof with a predetermined speed while the predetermined tension is applied to the polishing tape 3. Next, the polishing head 10 brings the polishing surface 3a of the polishing tape 3 into contact with the first surface 1 of the wafer W to start the polishing of the first surface 1 of the wafer W in the presence of  
20 the rinsing liquid. Further, the polishing-head moving mechanism 191 moves the polishing head 10, the polishing-tape supply mechanism 141, the guide rollers 153a, 153b, 153c, and 153d, and the tape advancing device 146 outward in the radial direction of the wafer W, while the polishing head 10 presses the first surface 1 of the wafer W with the polishing tape 3. During the polishing of the wafer W, the rinsing-liquid supply nozzle 127 and the  
25 protecting-liquid supply nozzle 128 continuously supply the rinsing liquid and the protecting liquid to the wafer W.

[0066] When the polishing head 10 reaches the outermost portion of the first surface 1 of the wafer W, the operation controller 180 terminates the polishing of the wafer W.

Specifically, the polishing head 10 lowers the pressing tool 12 to separate the polishing tape 3 from the first surface 1 of the wafer W. Thereafter, the operation controller 180 stops the operations of the substrate holder 110, the rinsing-liquid supply nozzle 127, the protecting-liquid supply nozzle 128, the polishing-tape supply mechanism 141, and the tape advancing device 146 to terminate the polishing the wafer W. In one embodiment, the polishing-head moving mechanism 191 may reciprocate the polishing head 10 between the outermost portion and the center O1 of the first surface 1 of the wafer W.

[0067] FIG. 15 is a diagram showing another embodiment of the polishing apparatus 100. FIG. 16 is a top view of the polishing apparatus 100 shown in FIG. 15. Details of the present embodiment, which will not be particularly described, are the same as those of the embodiments described with reference to FIGS. 13 and 14, and duplicated descriptions will be omitted. The rinsing-liquid supply nozzle 127 is not shown in FIG. 15. The polishing apparatus 100 of the present embodiment includes polishing-head assemblies 11A and 11B, polishing-tape supply mechanisms 141A and 141B configured to supply polishing tapes 3 to the polishing head assemblies 11A and 11B, respectively, and tape advancing devices 146A and 146B configured to advance the polishing tapes 3 in the longitudinal direction thereof. The polishing head assembly 11A includes polishing heads 10A and 10B. Similarly, the polishing head assembly 11B includes polishing heads 10A and 10B. The polishing head assembly 11A is supported by a support member 131A, and the polishing head assembly 11B is supported by a support member 131B. The polishing tape 3 supplied to the polishing head assembly 11A is supported by guide rollers 353a, 353b, 353c, and 353d, and the polishing tape 3 supplied to the polishing head assembly 11B is supported by guide rollers 453a, 453b, 453c, and 453d. The polishing head 10A corresponds to the polishing head 10 described with reference to FIGS. 1 to 6, and the polishing head 10B corresponds to the polishing head 10 described with reference to FIGS. 7 to 11. Configurations of the polishing-tape supply mechanisms 141A and 141B, the tape advancing devices 146A and 146B, the support members 131A and 131B, the guide rollers 353a, 353b, 353c, and 353d, and the guide rollers 453a, 453b, 453c, and 453d are the same as the configurations of the

polishing-tape supply mechanism 141, the tape advancing device 146, the support member 131, and the guide rollers 153a, 153b, 153c, and 153d described with reference to FIG 13. The polishing apparatus 100 of the present embodiment does not include the polishing-head moving mechanism 191. Therefore, during the polishing, positions of the polishing head assemblies 11A and 11B are fixed. The coating layer 58 described with reference to FIG. 5 12 can be applied to the polishing heads 10A and 10B of the present embodiment.

[0068] The plurality of polishing heads 10A and 10B are arranged at different distances from an axis CP of the substrate holder 110 (or the center O1 of the first surface 1 of the wafer W). A distance d1 from the axis CP of the substrate holder 110 to an outermost end 10 of the entire plurality of portions 41 is longer than a radius d2 of the wafer W.

[0069] During the polishing, the tape advancing device 146A advances the polishing tape 3 in a direction indicated by an arrow F in FIGS. 15 and 16, and the tape advancing device 146B advances the polishing tape 3 in a direction indicated by an arrow G in FIGS. 15 and 16. Specifically, each polishing tape 3 is advanced from a central portion toward an outer 15 peripheral portion of the wafer W. As a result, the polishing debris generated by the polishing of the wafer W can be discharged efficiently from the center portion of the wafer W to the outside of the wafer W. The plurality of polishing heads 10A and 10B are configured to be operable independently of each other. The polishing heads 10A and 10B of the polishing head assembly 11A are arranged along the advancing direction F of the 20 polishing tape 3 (i.e., the longitudinal direction of the polishing tape 3) with a gap therebetween. The polishing heads 10A and 10B of the polishing head assembly 11B are arranged along the advancing direction G of the polishing tape 3 (i.e., the longitudinal direction of the polishing tape 3) with a gap therebetween. Each of the plurality of portions 41 of the present embodiment extends obliquely with respect to the advancing directions F and G of the polishing tape 3. When viewed from the advancing direction F or the 25 advancing direction G of the polishing tape 3, the plurality of portions 41 are continuously arranged along a direction perpendicular to the advancing directions F and G of the polishing tape 3. Further, when viewed from the advancing direction F or the advancing direction G

of the polishing tape 3, the plurality of portions 41 are continuously arranged with no gap.

[0070] The plurality of portions 41 are not aligned in a straight line, but these portions 41 are located at different distances from the axial center CP of the substrate holder 110. Therefore, when the wafer W is rotating, each region of the first surface 1 of the wafer W passes through any of the plurality of portions 41. As a result, the plurality of elastic members 40 can press the polishing tape 3 against the entire surface of the first surface 1 of the wafer W.

[0071] FIG. 17 is a diagram showing another embodiment of the polishing head 10. The polishing head 10 of the present embodiment is also suitably used for a polishing apparatus that polishes a periphery of a substrate (e.g., a wafer). In the present specification, the periphery of the substrate is defined as a region including a bevel portion located at the outermost periphery of the substrate and a top-edge portion and a bottom-edge portion located radially inwardly of the bevel portion.

[0072] FIGS. 18A and 18B are enlarged cross-sectional views showing the periphery of the substrate. More specifically, FIG. 18A is a cross-sectional view of a substrate of a so-called straight type, and FIG. 18B is a cross-sectional view of a substrate of a so-called round type. In the substrate Wf of FIG. 18A, the bevel portion is an outermost peripheral surface (indicated by symbol B) constituting an upper slope portion (or an upper bevel portion) P, a lower slope portion (or a lower bevel portion) Q, and a side portion (or an apex) R of the substrate Wf. In the substrate Wf of FIG. 18B, the bevel portion is a portion (indicated by symbol B) constituting an outermost peripheral surface of the substrate Wf and having a curved cross section. The top-edge portion is an annular flat portion E1 located radially inwardly of the bevel portion B, and located in a device surface of the substrate Wf. The bottom-edge portion is an annular flat portion E2 located at an opposite side from the top-edge portion and located radially inwardly of the bevel portion B. The top-edge portion E1 may include a region in which devices are formed.

[0073] Referring back to FIG. 17, the polishing head 10 includes a pressing mechanism 241 configured to press a polishing surface 3a of a polishing tape 3 against a wafer W with a

predetermined force. Further, the polishing head 10 includes a tape advancing device 252 configured to advance the polishing tape 3 from a later-described tape feeding reel 243 (not shown in FIG. 17) to a later-described tape take-up reel 244 (not shown in FIG. 17). The polishing head 10 has a plurality of guide rollers 253, 254, 255, 256, 257, 258, and 259, and these guide rollers are arranged to guide the polishing tape 3 such that the polishing tape 3 advances in a direction perpendicular to a tangential direction of the wafer W.

[0074] The tape advancing device 252 provided on the polishing head 10 includes a tape advancing roller 252a, a tape holding roller 252b, and a motor M configured to rotate the tape advancing roller 252a. The motor M is mounted to a side surface of the polishing head 10, and the tape advancing roller 252a is attached to a rotating shaft of the motor M. The tape holding roller 252b is arranged adjacent to the tape advancing roller 252a. The tape holding roller 252b is supported by a not-shown mechanism that generate a force in a direction indicated by an arrow NF in FIG. 17 (direction toward the tape advancing roller 252a), so that the tape holding roller 252b presses the tape advancing roller 252a.

[0075] When the motor M rotates in a direction indicated by an arrow shown in FIG. 17, the tape advancing roller 252a rotates and can advance the polishing tape 3 from the tape feeding reel 243 (not shown in FIG. 17) via the polishing head 10 to the tape take-up reel 244 (not shown in FIG. 17). The tape holding roller 252b is configured to rotate about its own axis and rotates as the polishing tape 3 is advanced.

[0076] The pressing mechanism 241 includes a pressing tool 12 configured to press the polishing tape 3 against the wafer W, and an air cylinder (or driving mechanism) 251 configured to move the polishing tool 12 toward the periphery of the wafer W. The air cylinder 251 is a so-called single rod cylinder. By controlling an air pressure supplied to the air cylinder 251, a force for pressing the polishing tape 3 against the wafer W is regulated.

The pressing tool 12 is disposed at a back side of the polishing tape 3.

[0077] FIG. 19 is a diagram of the pressing tool 12 of the present embodiment as viewed from a front side (polishing-tape side). FIG. 20 is a diagram of the pressing tool 12 shown in FIG. 19 as viewed from a side surface 48. FIG. 21 is a diagram of the pressing tool 12

shown in FIG. 19 as viewed from a side surface 49. Details of the pressing tool 12 of the present embodiment, which will not be particularly described, are the same as those of the embodiments described with reference to FIGS. 1 to 5, and duplicated descriptions will be omitted. As shown in FIG. 19, a pressing-tool body 43 of the pressing tool 12 of the present embodiment includes two raised portions 43a and 43b with a gap therebetween and a base portion 43c coupled to the raised portions 43a and 43b. The raised portion 43a and the raised portion 43b are arranged in parallel. The raised portions 43a and 43b and the base portion 43c may be formed integrally.

[0078] The raised portion 43a has a pressing surface 44a, and the raised portion 43b has a pressing surface 44b. In other words, the pressing surface 44 of the present embodiment is constituted of the pressing surface 44a and the pressing surface 44b arranged with a gap therebetween. The pressing surface 44a and the pressing surface 44b are arranged in parallel. The pressing surfaces 44a and 44b have fitting grooves 45a and 45b, respectively. When viewed from the front side of the pressing tool 12, the fitting grooves 45a and 45b are arranged symmetrically about a center line Ct and are curved inward toward the center line Ct. More specifically, the fitting grooves 45a and 45b have an arc shape having the same curvature as a curvature of the wafer W (not shown in FIG. 19) as an object to be polished, which will be described later.

[0079] The pressing tool 12 includes two elastic members 40a and 40b. The elastic member 40a is put on the pressing-tool body 43 with the elastic member 40a elastically deformed, while the elastic member 40a fits in the fitting groove 45a. The elastic member 40b is put on the pressing-tool body 43 with the elastic member 40b elastically deformed, while the elastic member 40b fits in the fitting groove 45b. The elastic member 40a has a portion 41a fitting in the fitting groove 45a, and the elastic member 40b has a portion 41b fitting in the fitting groove 45b. These portions 41a and 41b protrude from the pressing surfaces 44a and 44b, respectively. The portions 41a and 41b of the elastic members 40a and 40b are curved inward toward the center line Ct and have the same curvature as the curvature of the wafer W.

[0080] The pressing-tool body 43 of the present embodiment has two fitting grooves 60a and 60b located in a back surface 46 which is an opposite side from the pressing surfaces 44a and 44b. The fitting grooves 60a and 60b extend from the side surface 48 to the other side surface 49. The elastic member 40a fits in the fitting groove 60a, and the elastic member 40b fits in the fitting groove 60b. As a result, the elastic member 40 is secured stably to the pressing-tool body 43. In one embodiment, the pressing-tool body 43 may have fitting grooves, in which the elastic members 40a and 40b fit, in the side surface 48 and/or the side surface 49.

[0081] The raised portion 43a has a tapered surface 56a extending obliquely from the pressing surface 44a, and the raised portion 43b has a tapered surface 56b extending obliquely from the pressing surface 44b. More specifically, the tapered surface 56a extends obliquely from the pressing surface 44a toward the base portion 43c and is coupled to a side surface 47a. The tapered surface 56b extends obliquely from the pressing surface 44b toward the base portion 43c and is coupled to a side surface 50a. These tapered surfaces 56a and 56b can prevent the polishing tape 3 from contacting the pressing-tool body 43 when the elastic members 40a and 40b press the polishing tape 3 against the wafer W. The coating layer 58 described with reference to FIG. 12 can be applied to the pressing tool 12 of the present embodiment.

[0082] FIGS. 22 and 23 are diagrams showing another embodiment of the pressing tool 12 described with reference to FIGS. 19 to 21. FIG. 22 is a diagram of the pressing tool 12 as viewed from the side surface 48. FIG. 23 is a diagram of the polishing tool 12 as viewed from the side surface 49. As shown in FIGS. 22 and 23, the embodiment described with reference to FIGS. 7 to 11 may be applied to the pressing tool 12 described with reference to FIGS. 19 to 21. Details of the pressing tool 12 of the present embodiment, which will not be particularly described, are the same as those of the embodiments described with reference to FIGS. 7 to 11 and FIGS. 19 to 21, and duplicated descriptions will be omitted. The pressing-tool body 43 of the present embodiment has a protrusion 54 on the side surface 48, and has a protrusion 55 on the side surface 49. The pressing-tool body 43 does not have the

fitting grooves 60a and 60b. In the present embodiment, the pressing-tool body 43 includes one protrusion 54 and one protrusion 55, while in one embodiment, the pressing-tool body 43 may have two or more protrusions 54 and two or more protrusions 55.

[0083] In the present embodiment, the two portions 41a and 41b fitting in the fitting  
5 grooves 45a and 45b, respectively, can be configured by one elastic member 40. As a result, a cost of replacement parts can be reduced. In addition, since the elastic member 40 of the present embodiment is not supported by the back surface 46 of the pressing-tool body 43, the elastic member 40 can be replaced easily.

[0084] FIG. 24 is a diagram showing an embodiment of a polishing apparatus including  
10 the polishing head 10 described with reference to FIGS. 17 and 19 to 23. A polishing apparatus 200 shown in FIG. 24 is suitably used as a polishing apparatus that polishes a periphery of a substrate (e.g., a wafer). The polishing apparatus 200 includes a substrate holder 210 configured to hold and rotate a wafer W, which is an object to be polished, polishing head 10 configured to bring a polishing tool into contact with a periphery of the  
15 wafer W held by the substrate holder 210 to polish the periphery of the wafer W, a lower supply nozzle 222 configured to supply liquid to a lower surface of the wafer W, and an upper supply nozzle 230 configured to supply liquid onto an upper surface of the wafer W. An example of the liquid supplied to the wafer W includes pure water. During the polishing of the wafer W, the liquid is supplied from the lower supply nozzle 222 to the  
20 lower surface of the wafer, and the liquid is supplied from the upper supply nozzle 230 to the upper surface of the wafer W.

[0085] FIG. 24 shows the substrate holder 210 holding the wafer W. When the wafer W is held by the substrate holder 210, the polishing head 10 faces the periphery of the wafer W. The substrate holder 210 includes a holding stage 204 configured to hold the wafer W by  
25 vacuum suction, a shaft 205 coupled to a central portion of the holding stage 204, and a holding-stage driving mechanism 207 configured to rotate and vertically move the holding stage 204. The holding-stage driving mechanism 207 is configured to be able to rotate the holding stage 204 about its own axis Cr and move the holding stage 204 in a vertical

direction along the axis Cr.

[0086] The holding stage 204, the polishing head 10, the lower supply nozzle 222, the upper supply nozzle 230, and the holding stage 204 are disposed inside a partition wall 260. The inside of the partition wall 260 constitutes a polishing chamber in which the wafer W is  
5 polished. The partition wall 260 is arranged on a base plate 265. The shaft 205 extends through the base plate 265.

[0087] The holding-stage driving mechanism 207 includes a motor 214 as a stage rotating device configured to rotate the holding stage 204, and an air cylinder 217 configured to vertically move the holding stage 204. The motor 214 is fixed to a lower surface of the  
10 base plate 265. The holding stage 204 is rotated by the motor 214 via the shaft 205, a pulley 211a coupled to the shaft 205, a pulley 211b attached to a rotating shaft of the motor 214, and a belt 212 put on the pulleys 211a and 211b. The axis of rotation of the motor 214 extends parallel to the shaft 205. With such a configuration, the wafer W held on an upper surface of the holding stage 204 is rotated by the motor 214. The shaft 205 is coupled to  
15 the air cylinder 217 via a rotary joint 216 attached to a lower end of the shaft 205, and the shaft 205 and the holding stage 204 can be raised and lowered by the air cylinder 217.

[0088] The wafer W is placed on the upper surface of the holding stage 204 by a not-shown transfer mechanism such that the center O1 of the wafer W is on the axis Cr of the holding stage 204. The wafer W is held on the upper surface of the holding stage 204 with  
20 a device surface of the wafer W facing upward. With such a configuration, the substrate holder 210 can rotate the wafer W about the axis Cr of the holding stage 204 (i.e., the axis of the wafer W), and can raise and lower the wafer W along the axis Cr of the holding stage 204.

[0089] In the present embodiment, a polishing tape 3 having abrasive grains on its surface  
25 is used as an example of the polishing tool. The polishing apparatus 200 further includes a polishing-tape supply mechanism 242 configured to supply the polishing tape 3 to the polishing head 10 and configured to collect the polishing tape 3 from the polishing head 10. The polishing-tape supply mechanism 242 is arranged outside the partition wall 260. The

polishing-tape supply mechanism 242 includes a tape feeding reel 243 configured to supply the polishing tape 3 to the polishing head 10, and a tape take-up reel 244 configured to collect the polishing tape 3 that has been used for the polishing of the wafer W. Not-shown tension motors are coupled to the tape feeding reel 243 and the tape take-up reel 244,  
5 respectively. The tension motors apply a predetermined torque to the tape feeding reel 243 and the tape take-up reel 244, so that a predetermined tension can be generated in the polishing tape 3.

[0090] The polishing tape 3 is supplied to the polishing head 10 such that a polishing surface of the polishing tape 3 faces the periphery of the wafer W. The polishing tape 3 is  
10 supplied from the tape feeding reel 243 to the polishing head 10 through an opening 260a provided in the partition wall 260, and the used polishing tape 3 is collected by the tape take-up reel 244 through the opening 260a. The polishing-tape supply mechanism 242 further includes a plurality of guide rollers 245, 246, 247, and 248 for supporting the polishing tape 3. An advancing direction of the polishing tape 3 is guided by the guide rollers 245, 246,  
15 247, and 248.

[0091] The polishing apparatus 200 further includes a not-shown tilting mechanism. The polishing apparatus 200 can polish the periphery of the wafer W while changing a tilt angle of the polishing head 10 by the tilting mechanism. FIG. 25 is a diagram showing the polishing head 10 tilted upward by the tilting mechanism (not shown). FIG. 26 is a  
20 diagram showing the polishing head 10 tilted downward by the tilting mechanism.

[0092] As shown in FIG. 25, when the polishing head 10 is tilted upward, the portion 41a of the elastic member 40a is located above the periphery of the wafer W and faces the top-edge portion. As shown in FIG. 26, when the polishing head 10 is tilted downward, the portion 41b of the elastic member 40b is located below the periphery of the wafer W and  
25 faces the bottom-edge portion. When the top-edge portion is to be polished, the polishing surface 3a of the polishing tape 3 is pressed against the periphery (i.e., the top-edge portion) of the wafer W by the portion 41a of the elastic member 40a with the polishing head 10 tilted upward. When the bottom-edge portion is to be polished, the polishing surface 3a of the

polishing tape 3 is pressed against the periphery (i.e., the bottom-edge portion) of the wafer W by the portion 41b with the polishing head 10 tilted downward. Pressing forces of these portions 41a and 41b can be regulated by the air cylinder 251. During the polishing of the wafer W, a back surface of the polishing tape 3 is supported by the elastic member 40a or the elastic member 40b.

[0093] The polishing apparatus 200 includes an operation controller 280 configured to control operations of each component of the polishing apparatus 200. The polishing head 10, the substrate holder 210, the lower supply nozzle 222, the upper supply nozzle 230, the polishing-tape supply mechanism 242, and the tilting mechanism are electrically coupled to the operation controller 280. The operations of the polishing head 10, the substrate holder 210, the lower supply nozzle 222, the upper supply nozzle 230, the polishing-tape supply mechanism 242, and the tilting mechanism are controlled by the operation controller 280. During the polishing, the operation controller 280 operates the polishing-tape supply mechanism 242 and the tape advancing device 252 to advance the polishing tape 3 in a longitudinal direction thereof with a predetermined speed while a predetermined tension is exerted on the polishing tape 3.

[0094] The operation controller 280 is composed of at least one computer. The operation controller 280 includes a memory 280a and an arithmetic device 280b. The arithmetic device 280b includes a CPU (central processing unit), a GPU (graphic processing unit), etc. configured to perform arithmetic operations according to instructions contained in programs stored in the memory 280a. The memory 280a includes a main memory (e.g., a random-access memory) to which the arithmetic device 280b is accessible, and an auxiliary memory (e.g., a hard disk drive or a solid state drive) storing data and the programs therein.

[0095] FIG. 27 is a diagram showing a top-edge portion of the wafer W being polished. The polishing head 10 is moved with a constant speed in a direction indicated by arrows in FIG. 27 (i.e., a radially outward direction of the wafer W) by a moving mechanism constituted of a linear actuator (not shown) or the like, while pressing the polishing tape 3 against the wafer W. The operation of the moving mechanism is controlled by the

operation controller 280. In the present embodiment, since the portion 41a of the elastic member 40a fitting in the fitting groove 45a is curved along the periphery of the wafer W, a time when the polishing tape 3 is in contact with the wafer W is uniform over the entire top-edge portion. As a result, the entire top-edge portion can be polished uniformly. In addition, use of the curved portion 41a of the elastic member 40a can increase a contact length between the polishing tape 3 and the wafer W, and can therefore increase a polishing rate.

[0096] Since the fitting groove 45a and the fitting groove 45b are arranged symmetrically about the center line Ct, the portion 41b extends along the bottom-edge portion of the wafer W when the polishing head 10 is tilted downward such that the portion 41b of the elastic member 40b faces the bottom-edge portion as shown in FIG. 26. Therefore, as with the polishing of the top-edge portion, the bottom-edge portion can be polished accurately and uniformly by the portion 41b of the elastic member 40b.

[0097] In one embodiment, as shown in FIG. 28, the pressing tool 12 may further have a pressing pad (or bevel pad) 270 disposed between the raised portions 43a and 43b. The pressing pad 270 is made of an elastic closed-cell foam material, such as silicone rubber. When the pressing tool 12 is moved toward the wafer W by the air cylinder 251, the pressing pad 270 presses the polishing tape 3 from its back side against the bevel portion of the wafer W, and the polishing head 10 polishes the bevel portion of the wafer W. In order to reduce friction with the back surface of the polishing tape 3, a sheet whose front surface is covered with fluororesin may be attached to a front surface (pressing surface) of the pressing pad 270. The pressing pad 270 is removable by bolts or the like. The pressing tool 12 of the present embodiment can be applied to the embodiment described with reference to FIGS. 22 and 23.

[0098] FIG. 29 is a diagram showing the polishing head 10 when polishing the bevel portion of the wafer W. When the periphery of the wafer W is polished, as shown in FIG. 29, the polishing tape 3 is pressed against the periphery (e.g., the bevel portion) of the wafer W by the pressing mechanism 241 while the tilt angle of the polishing head 10 is continuously changed by the tilting mechanism (not shown).

[0099] Further, in one embodiment, when the polishing head 10 polishes any one of the top-edge portion and the bottom-edge portion, the pressing-tool body 43 may include only one of the two raised portions 43a and 43b, and may include only one of the two elastic members 40a and 40b. Further, in one embodiment, the polishing apparatus 200 may  
5 include a plurality of polishing heads 10 arranged in a circumferential direction of the holding stage 204.

[0100] The previous description of embodiments is provided to enable a person skilled in the art to make and use the present invention. Moreover, various modifications to these embodiments will be readily apparent to those skilled in the art, and the generic principles  
10 and specific examples defined herein may be applied to other embodiments. Therefore, the present invention is not intended to be limited to the embodiments described herein but is to be accorded the widest scope as defined by limitation of the claims.

### **Industrial Applicability**

[0101] The present invention is applicable to a polishing head for pressing a polishing tool  
15 against a substrate, such as a wafer. Further, the present invention is applicable to a polishing apparatus for polishing the substrate with such a polishing head.

## CLAIMS

[Claim 1] A polishing head for polishing a substrate, comprising:

an annular elastic member configured to press a polishing tool against the substrate;

and

5 a pressing-tool body having a pressing surface configured to press the polishing tool against the substrate via the elastic member,

wherein the pressing surface has a first fitting groove in which a first portion of the elastic member fits,

the first portion protrudes from the pressing surface,

10 the elastic member is put on the pressing-tool body with the elastic member elastically deformed, and

the polishing head is configured to press the polishing tool against the substrate by the first portion.

15 [Claim 2] The polishing head according to claim 1, wherein the elastic member is detachably put on the pressing-tool body.

[Claim 3] The polishing head according to claim 1 or 2, wherein the elastic member has a circular cross section.

20

[Claim 4] The polishing head according to any one of claims 1 to 3, wherein the elastic member is covered with a coating layer containing a fluororesin.

[Claim 5] The polishing head according to any one of claims 1 to 4, wherein the pressing-tool body further has a tapered surface extending obliquely from the pressing surface.

25 [Claim 6] The polishing head according to any one of claims 1 to 5, wherein a side

surface of the pressing-tool body has a second fitting groove in which a second portion of the elastic member fits.

[Claim 7]           The polishing head according to any one of claims 1 to 5, wherein  
5           the pressing-tool body has a protrusion on a side surface of the pressing-tool body,  
and  
          the protrusion supports the elastic member.

[Claim 8]           The polishing head according to any one of claims 1 to 7, wherein  
10           the first fitting groove comprises a plurality of first fitting grooves located away  
from each other, and  
          the first portion comprises a plurality of first portions fitting in the plurality of first  
fitting grooves, respectively.

15 [Claim 9]           The polishing head according to any one of claims 1 to 8, wherein the first  
fitting groove has an arc shape having the same curvature as a curvature of the substrate.

[Claim 10]          A polishing apparatus comprising:  
          a substrate holder configured to hold a substrate; and  
20           the polishing head, according to any one of claims 1 to 9, configured to press a  
polishing tool against the substrate to polish the substrate.
