5 The present invention relates to novel potent PPAR-alpha-activating compounds for treating, for example, coronary heart disease, and to their preparation.

10 In spite of many successful therapies, coronary heart disease (CHD) remains a serious public health problem. Treatment with statins, which inhibit HMG-CoA reductase, successfully lowers both LDL cholesterol plasma concentrations and the mortality of patients at risk; however, convincing treatment strategies for the therapy of patients having an unfavourable HDL/LDL cholesterol ratio or hypertriglyceridaemia are still not available to date.

15 Currently, fibrates are the only therapy option for patients of these risk groups. They act as weak agonists of the peroxisome-proliferator-activated receptor (PPAR)-alpha (*Nature* 1990, 347, 645-50). A disadvantage of the fibrates which have hitherto been approved is that their interaction with the receptor is only weak, requiring high daily doses and causing considerable side-effects.

20 WO 00/23407 describes PPAR modulators for treating obesity, atherosclerosis and/or diabetes.

It was an object of the present invention to provide novel compounds which can be used as PPAR-alpha modulators.

10 The process according to the invention is generally carried out at atmospheric pressure. However, it is also possible to carry out the process under elevated pressure or under reduced pressure (for example in a range of from 0.5 to 5 bar).

15 Solvents which are suitable for the process are customary organic solvents which do not change under the reaction conditions. These include ethers, such as diethyl ether, dioxane, tetrahydrofuran, glycol dimethyl ether, or hydrocarbons, such as benzene, toluene, xylene, hexane, cyclohexane or mineral oil fractions, or halogenated hydrocarbons, such as dichloromethane, trichloromethane, carbon tetrachloride, dichloroethylene, trichloroethylene or chlorobenzene, or ethyl acetate, pyridine, 20 dimethyl sulphoxide, dimethylformamide, N,N'-dimethylpropyleneurea (DMPU), N-methylpyrrolidone (NMP), acetonitrile, acetone or nitromethane. It is also possible to use mixtures of the solvents mentioned.

25 Solvents which are preferred for process step (II) + (III) $\rightarrow$ (Ia) are dichloromethane and dimethylformamide. For process step (IV) + (V) $\rightarrow$ (Ia), preference is given to dimethylformamide.

Particular preference is

Preference is given to sodium bicarbonate.
30

The hydrolysis of the carboxylic acid esters in the process step (Ia) or (Ib) $\rightarrow$ (Ic) is carried out by customary methods by treating the esters in inert solvents with bases, the salts that are initially formed being converted by treatment with acid into the free carboxylic acids. In the case of the tert-butyl esters, the hydrolysis is preferably carried out using acids.

Suitable solvents for the hydrolysis of the carboxylic acid esters are water or the organic solvents which are customary for ester cleavage. These preferably include alcohols, such as methanol, ethanol, propanol, isopropanol or butanol, or ethers, such as tetrahydrofuran or dioxane, dimethylformamide, dichloromethane or dimethyl sulphoxide. It is also possible to use mixtures of the solvents mentioned. Preference is given to water/tetrahydrofuran and, in the case of the reaction with trifluoroacetic acid, to dichloromethane and, in the case of hydrogen chloride, to tetrahydrofuran, diethyl ether, dioxane or water.

Bases suitable for the hydrolysis are the customary inorganic bases. These preferably include alkali metal hydroxide or alkaline earth metal hydroxide, such as, for example, sodium hydroxide, lithium hydroxide, potassium hydroxide or barium hydroxide, or alkali metal carbonates, such as sodium carbonate or potassium carbonate, or sodium bicarbonate. Particular preference is given to using sodium hydroxide or lithium hydroxide.

Suitable acids are, in general, trifluoroacetic acid, sulphuric acid, hydrogen chloride, hydrogen bromide and acetic acid, or mixtures thereof, if appropriate with addition of water. Preference is given to hydrogen chloride or trifluoroacetic acid in the case of the tert-butyl esters and to hydrochloric acid in the case of the methyl esters.

In the case of compounds of the general formula (Ia) or (Ib) prepared by solid-phase synthesis and attached to a polymeric support via the carboxylic acid group, the cleavage from the resin to give the compounds of the general formula (Ic) is likewise

carried out by the above-described customary methods for carboxylic acid ester hydrolysis. Here, preference is given to using trifluoroacetic acid.

When carrying out the hydrolysis, the base or the acid is generally employed in an amount of from 1 to 100 mol, preferably from 1.5 to 40 mol, based on 1 mole of the ester.

The hydrolysis is generally carried out in a temperature range of from 0°C to +100°C, preferably from 0°C to +50°C.

and finally selectively hydrolysing the carboxylic acid ester grouping $-COOR^{15}$ in these compounds to the carboxylic acid.

10 The entire process can also be carried out as solid-phase synthesis. In this case, the compounds of the general formula (VII) or (XII) are attached as carboxylic acid esters to a suitable support resin, the further reactions are carried out on solid phase and the target compound is finally cleaved off from the resin. Solid-phase synthesis and the attachment and the cleavage from the resin are customary standard
15 techniques. To mention but one example from the extensive literature, reference is made to the publication "Linkers for Solid Phase Organic Synthesis", Ian W. James, *Tetrahedron* 55, 4855-4946 (1999).

20 The reaction (VII) + (VIII) $\rightarrow$ (IX) or (XII) + (XIII) $\rightarrow$ (XIV) is carried out in the solvents which are customary for reductive amination and inert under the reaction conditions, if appropriate in the presence of an acid. The solvents include, for example, water, dimethylformamide, tetrahydrofuran, dichloromethane, dichloroethane, or alcohols such as methanol, ethanol, propanol, isopropanol or butanol; it is also possible to use mixtures of the solvents mentioned. Preference is given to
25 methanol and ethanol in each case with addition of acetic acid.

Suitable reducing agents for the reaction (VII) + (VIII) $\rightarrow$ (IX) or (XII) + (XIII) $\rightarrow$ (XIV) are complex aluminium hydrides or boron hydrides, such as, for example, diisobutylaluminium hydride, sodium borohydride, sodium triacetoxyborohydride, sodium cyanoborohydride or tetrabutylammonium borohydride, or else catalytic hydrogenation in the presence of transition metal catalysts such as, for example, palladium, platinum, rhodium or Raney nickel. Preferred reducing agents are sodium cyanoborohydride, sodium triacetoxyborohydride and tetrabutylammonium borohydride.

The reaction (VII) + (VIII) $\rightarrow$ (IX) or (XII) + (XIII) $\rightarrow$ (XIV) is generally carried out in a temperature range of from 0°C to +40°C.

The reaction (IX) + (X) $\rightarrow$ (XI) or (XIV) + (XV) $\rightarrow$ (XVI) is carried out in the customary solvents which are inert under the reaction conditions. Preference is given to dimethylformamide, tetrahydrofuran and dioxane.

Suitable bases for the reaction (IX) + (X) $\rightarrow$ (XI) or (XIV) + (XV) $\rightarrow$ (XVI) are the customary inorganic or organic bases. Preference is given to triethylamine.

The reaction (IX) + (X) $\rightarrow$ (XI) or (XIV) + (XV) $\rightarrow$ (XVI) is generally carried out in a temperature range of from 0°C to +100°C.

The reaction (XI) $\rightarrow$ (II) or (XVI) $\rightarrow$ (II) is carried out in the solvents which are customary for ester cleavage and inert under the reaction conditions. In the case of the ester hydrolysis, these are preferably tetrahydrofuran, dioxane and alcohols, such as methanol and ethanol, in each case in a mixture with water. In the case of the cleavage of silyl esters, preference is given to using dioxane or tetrahydrofuran.

Suitable bases for the reaction (XI) $\rightarrow$ (II) or (XVI) $\rightarrow$ (II) are, in the case of the hydrolysis, the customary inorganic bases. Preference is given to lithium hydroxide,

sodium hydroxide and potassium hydroxide. In the case of the cleavage of silyl esters, preference is given to using tetrabutylammonium fluoride.

5 The reaction (XI) $\rightarrow$ (II) or (XVI) $\rightarrow$ (II) is generally carried out in a temperature range of from 0°C to +100°C.

The compounds of the general formula (IV) correspond to the compounds of the general formula (IX) or (XIV) and can be prepared as described above.

10 The compounds of the general formulae (III), (V), (VI), (VII), (VIII), (X), (XII), (XIII) and (XV) are commercially available, known or can be prepared by customary methods [cf., for example, P.J. Brown et al., *J. Med. Chem.* 42, 3785-88 (1999)].

15 The compounds of the formula (I) according to the invention have a surprising and useful spectrum of pharmacological activity and can therefore be used as versatile medicaments. In particular, they are suitable for treating coronary heart diseases, for the prophylaxis of myocardial infarction and for the treatment of restenosis after coronary angioplasty or stenting. The compounds of the formula (I) according to the invention are preferably suitable for treating arteriosclerosis and
20 hypercholesterolaemia, for increasing pathogenically low HDL levels and for lowering elevated triglyceride, fibrinogen and LDL levels. In addition, they can be used for treating obesity, diabetes, for treating the metabolic syndrome (glucose intolerance, hyperinsulinaemia, dyslipidaemia and high blood pressure owing to insulin resistance), hepatic fibrosis and cancer.

25 The activity of the compounds according to the invention can be examined, for example, *in vitro* by the transactivation assay described in the experimental section.

The activity of the compounds according to the invention *in vivo* can be examined,
30 for example, by the tests described in the experimental section.

Suitable administration forms for administering the compounds of the general formula (I) are all customary administration forms, i.e. oral, parenteral, inhalative, nasal, sublingual, rectal or external, for example transdermal, preferably oral or parenteral, administration forms. In the case of parenteral administration, particular
5 mention has to be made of intravenous, intramuscular and subcutaneous administration, for example as a subcutaneous depot. Very particular preference is given to oral administration.

Here, the active compounds can be administered on their own or in the form of
10 preparations. Preparations suitable for oral administration are, inter alia, tablets, capsules, pellets, sugar-coated tablets, pills, granules, solid and liquid aerosols, syrups, emulsions, suspensions and solutions. Here, the active compound has to be present in such an amount that a therapeutic effect is obtained. In general, the active compound can be present in a concentration of from 0.1 to 100% by weight, in
15 particular from 0.5 to 90% by weight, preferably from 5 to 80% by weight. In particular, the concentration of active compound should be 0.5 – 90% by weight, i.e. the active compound should be present in amounts sufficient to reach the dosage range stated.

20 To this end, the active compounds can be converted in a manner known per se into the customary preparations. This is carried out using inert non-toxic pharmaceutically suitable excipients, auxiliaries, solvents, vehicles, emulsifiers and/or dispersants.

Auxiliaries which may be mentioned are, for example: water, non-toxic organic
25 solvents, such as, for example, paraffins, vegetable oils (for example sesame oil), alcohols (for example ethanol, glycerol), glycols (for example polyethylene glycol), solid carriers, such as natural or synthetic ground minerals (for example talc or silicates), sugar (for example lactose), emulsifiers, dispersants (for example polyvinylpyrrolidone) and glidants (for example magnesium sulphate).

In the case of oral administration, the tablets may, of course, also contain additives such as sodium citrate, together with additives such as starch, gelatine and the like. Aqueous preparations for oral administration may furthermore comprise flavour improvers or colorants.

5

In the case of oral administration, preference is given to administering dosages of from 0.001 to 5 mg/kg, preferably from 0.005 to 3 mg/kg, of body weight per 24 hours.

At -78°C, 34.7 ml (69.4 mmol) of a 2 M lithium diisopropylamide solution are slowly added dropwise to a solution of 10.0 g (69.34 mmol) of *tert*-butyl 2-methylpropionate (Example I-1) in 100 ml of tetrahydrofuran. After the addition has ended, the mixture is stirred at -78°C for 1 h, and a solution of 15.76 g

The combined organic phases are washed with NaHCO_3 solution, dried over sodium sulphate and freed from the solvent under reduced pressure. Distillative purification of the residue under oil pump vacuum gives 16.75 g (85%) of *tert*-butyl 3-(4-bromophenyl)-2,2-dimethylpropionate.

$^1\text{H-NMR}$ (200 MHz, DMSO): δ = 1.06 (s, 6H); 1.38 (s, 9H); 2.74 (s, 2H); 7.10 (d, 2H); 7.47 (d, 2H).

0.842 g (1.49 mmol) of the compound from Example 3-7 is initially charged in 10 ml of dichloromethane. At room temperature, 10 ml of trifluoroacetic acid are added. The reaction mixture is stirred at room temperature for 2 hours. The mixture is then concentrated under reduced pressure using a rotary evaporator. The residue is taken up in ethyl acetate and washed with water, 20% strength sodium acetate solution, water and saturated sodium chloride solution. The organic phase is dried over magnesium sulphate and freed from the solvent under reduced pressure. The product is purified chromatographically on silica gel (dichloromethane/methanol 30:1) and then dried under reduced pressure. This gives 0.648 g (85% of theory) of the title compound.

0.4 g (0.78 mmol) of the compound from Example 3-7 are dissolved in 4 ml of ethyl acetate. At 40°C, first 8 ml of 1N hydrochloric acid (in diethyl ether) and then 12 ml of diethyl ether are added. The precipitated crystals are filtered off with suction, washed with a mixture of ethyl acetate and diethyl ether (ratio 1:1) and then dried at 40°C under reduced pressure for 20 hours. This gives 0.362 g (84.5% of theory) of the title compound.

0.303 g (0.94 mmol) of tert-butyl 2-(4-[[2-methoxyethyl]amino]methyl]phenoxy)-2-methylpropanoate (Example III-33) is initially charged in 5 ml of dimethylformamide. At room temperature, 0.319 g (1.03 mmol) of 2-bromo-N-(4-cyclohexyl-2-methylphenyl)acetamide (Example III-19) and 0.086 g (1.03 mmol) of sodium bicarbonate are added. The mixture is stirred at 90°C for 2 hours. The reaction mixture is then allowed to cool, and water is added. The mixture is extracted with ethyl acetate and the organic phase is washed with water and saturated sodium chloride solution. The organic phase is dried over sodium sulphate and freed from the solvent under reduced pressure. The residue is purified chromatographically on silica gel (cyclohexane/ethyl acetate 3:1) and the product is dried under reduced pressure. This gives 0.464 g (90% of theory) of the title compound.

¹H-NMR (300 MHz, CDCl₃): δ = 1.20-1.45 (m, 14H); 1.50 (s, 6H); 1.70-1.90 (m, 5H); 2.25 (s, 3H); 2.36-2.48 (m, 1H); 2.80 (t, 2H); 3.25 (s, 5H); 3.5 (t, 2H); 3.69 (s, 2H); 6.80 (d, 2H); 6.98- 7.06 (m, 2H); 7.15-7.25 (m, 2H); 7.85 (d, 1H); 9.25 (br s, 1H).

0.398 g (0.72 mmol) of the compound from Example 3-10 is initially charged in 5 ml of dichloromethane. At room temperature, 5 ml of trifluoroacetic acid are added. The reaction mixture is stirred at room temperature for 2 hours. The mixture is then concentrated under reduced pressure using a rotary evaporator. The residue is taken

up in ethyl acetate and washed with water, 20% strength sodium acetate solution, water and saturated sodium chloride solution. The organic phase is dried over magnesium sulphate and freed from the solvent under reduced pressure. The product is purified chromatographically on silica gel (dichloromethane/methanol 30:1). With heating, the residue is dissolved in dichloromethane, 1N hydrochloric acid in diethyl ether is added and n-heptane is added dropwise until the mixture becomes slightly turbid. The product is filtered off with suction, washed with diethyl ether and dried at 40°C under reduced pressure. This gives 0.187 g (49% of theory) of the title compound.

20

Example A

Cellular transactivation assay:

25

Test principle:

A cellular assay is used to identify activators of the peroxisome proliferator-activated receptor alpha (PPAR-alpha).

Since mammalian cells contain different endogenous nuclear receptors which may complicate an unambiguous interpretation of the results, an established chimera system is used in which the ligand binding domain of the human PPAR α receptor is fused to the DNA binding domain of the yeast transcription factor GAL4. The resulting GAL4-PPAR α chimera is co-transfected and stably expressed in CHO cells having a reporter construct.

Cloning:

The GAL4-PPAR α expression construct contains the ligand binding domain of PPAR α (amino acids 167-468), which is PCR-amplified and cloned into the vector pcDNA3.1. This vector already contains the GAL4 DNA binding domain (amino acids 1-147) of the vector pFC2-dbd (Stratagene). The reporter construct, which contains five copies of the GAL4 binding site upstream of a thymidine kinase promoter, expresses firefly luciferase (*Photinus pyralis*) following activation and binding of GAL4-PPAR α .

Transactivation assay (luciferase reporter):

CHO (chinese hamster ovary) cells are sown in DMEM/F12 medium (BioWhittaker), supplemented by 10% foetal calf serum, 1% penicillin/streptomycin (GIBCO), at a cell density of 2×10^3 cells per well in a 384 well plate (Greiner). The cells are cultivated at 37°C for 48 h and then stimulated. To this end, the substances to be tested are taken up in CHO-A-SFM medium (GIBCO), supplemented by 10% foetal calf serum, 1% penicillin/streptomycin (GIBCO) and added to the cells. After a stimulation period of 24 hours, the luciferase activity is measured using a video camera. The relative light units measured give, as a function of the substrate concentration, a sigmoidal stimulation curve. The EC₅₀ values are calculated using the computer programme GraphPad PRISM (Version 3.02).

In this test, the compounds according to the invention of Examples 3-4, 3-6, 3-60, 1-9, 2-7 and 2-12 show EC₅₀ values of from 0.04 to 200 nM.

Example B

Determination of fibrinogen:

To determine the effect on the plasma fibrinogen concentration, male Wistar rats are
5 treated with the substance to be examined for a period of 4-9 days, by administration
via a stomach tube or by mixing the substance with the feed. In terminal anaesthesia,
citratated blood is then obtained by heart puncture. The plasma fibrinogen levels are
determined using the Clauss method [Clauss A., *Acta Haematol.* 17, 237-46 (1957)]
by measuring the thrombin time using human fibrinogen as standard. In some cases,
10 parallel determinations are carried out using a turbidometric method [Becker U.,
Bartl K., Wahlefeld A. W., *Thrombosis Res.* 35, 475-84 (1984)] where batroxobin is
used instead of thrombin.

Example C

15 **Description of the test for finding pharmacologically active substances which
increase apoprotein A1 (ApoA1) and HDL cholesterol (HDL-C) concentrations
in the serum of transgenic mice transfected with the human ApoA1 gene
(hApoA1):**

20 The substances to be examined in vivo for their HDL-C-increasing activity are
administered orally to male transgenic hApoA1 mice. One day prior to the start of the
experiment, the animals are randomized into groups with the same number of
animals, generally n = 7-10. During the entire experiment, the animals have drinking
water and feed ad libitum. The substances are administered orally once a day for
25 7 days. To this end, the test substances are dissolved in a solution of Solutol HS 15 +
ethanol + saline (0.9%) in a ratio of 1+1+8 or in a solution of Solutol HS 15 + saline
(0.9%) in a ratio of 2+8. The dissolved substances are administered in a volume of
10 ml/kg of body weight using a stomach tube. Animals which have been treated in
exactly the same manner but have only been given the solvent (10 ml/kg of body
30 weight), without test substance, serve as control group.

Prior to the first administration of substance, a blood sample from each of the mice is taken by puncture of the retroorbital venous plexus, to determine ApoA1, serum cholesterol, HDL-C and serum triglycerides (TG) (zero value). Subsequently, using a stomach tube, the test substance is administered for the first time to the animals.

5 24 hours after the last administration of substance (on day 8 after the start of the treatment), another blood sample is taken from each animal by puncture of the retroorbital venous plexus, to determine the same parameters. The blood samples are centrifuged and, after the serum has been obtained, cholesterol and TG are determined photometrically using an EPOS Analyzer 5060 (Eppendorf-Gerätebau,

10 Netheler & Hinz GmbH, Hamburg). The said determinations are carried out using commercial enzyme tests (Boehringer Mannheim, Mannheim).

To determine the HDL-C, the non-HDL-C fraction is precipitated using 20% PEG 8000 in 0.2 M glycine buffer pH 10. From the supernatant, the cholesterol is

15 determined UV-photometrically (BIO-TEK Instruments Inc. USA) in a 96-well plate using a commercial reagent (Ecoline 25, Merck, Darmstadt).

Human mouse ApoA1 is determined with a Sandwich ELISA method using a polyclonal antihuman ApoA1 and a monoclonal antihuman ApoA1 antibody

20 (Biodesign International, USA). Quantification is carried out UV-photometrically (BIO-TEK Instruments, USA) using peroxidase-coupled anti-mouse-IGG antibodies (KPL, USA) and peroxidase substrate (KPL, USA)

The effect of the test substances on the HDL-C concentration is determined by

25 subtracting the value measured for the 1st blood sample (zero value) from the value measured for the 2nd blood sample (after the treatment). The mean of the differences of all HDL-C values of one group is determined and compared to the mean of the differences of the control group.

30 Statistical evaluation is carried out using student's t-test, after the variances have been checked for homogeneity.

Substances which increase the HDL-C of the treated animals in a statistically significant ($p < 0.05$) manner by at least 20%, compared to the control group, are considered to be pharmacologically effective.
