

NOVEL PYRAZOLO PYRIMIDINE DERIVATIVES AND THEIR USE AS MALT1 INHIBITORS

The present invention describes new pyrazolo-pyrimidine derivatives which are generally interacting with MALT1 proteolytic and/or autoproteolytic activity, and in particular which may inhibit said activity. The present invention further describes the synthesis of said new pyrazolo-pyrimidine derivatives, their use as a medicament, especially by interacting with MALT1 proteolytic and/or autoproteolytic activity.

Field of the Invention

The present invention relates to compounds of formula (I) or pharmaceutically acceptable salts thereof, and to their use in the treatment of a wide range of diseases or disorders, particularly MALT1-related diseases or disorders. This may include, but is not limited to autoimmune disorders and inflammatory diseases, such as rheumatoid arthritis, multiple sclerosis, systemic lupus erythematosus or vasculitic conditions, cancers of hematopoietic origin or solid tumors, including chronic myelogenous leukemia, myeloid leukemia, non-Hodgkin lymphoma and other B cell lymphomas.

Background of the invention

The essential role of MALT1 (mucosa associated lymphoid tissue lymphoma translocation protein 1) in influencing immune responses is described in numerous publications. For example, Rudi Beyaert et al. (WO 2009/065897) describe certain compounds as inhibitors of MALT1 proteolytic and/or autoproteolytic activity.

Studies in BCL10 and MALT 1 deficient mice seem to suggest their essential role in the signaling cascade from the antigen receptors to the transcription factor NFkB. Moreover chromosomal translocations leading to overexpression of BCL10 and MALT 1, or creating the constitutively active fusion protein API2-MALT1, appear to yield in an uncontrolled and stimulus-independent activation of NFkB. Inhibitors of the proteolytic activity of MALT1 have been described with activity in preclinical lymphoma models (Vincendeau et al. Int. J. Hematol. Oncol. 2013, 2, 409).

Moreover, certain publications appear to suggest the important role of MALT1 and its proteolytic function in signaling cascades triggered by innate cell receptors like Dectin

receptors and in signaling cascades triggered by G-protein coupled receptors in many cell types.

Consequently, there appears to be a desire to discover and develop potent MALT1 inhibitors comprising valuable pharmacological properties.

Summary of the invention

The present invention describes novel pyrazolo-pyrimidine derivatives according to formula (I) or pharmaceutically acceptable salts thereof as potent inhibitors of MALT1 which may hence be useful in the treatment of a wide range of diseases or disorders, particularly MALT1-related diseases or disorders. This may include, but is not limited to autoimmune disorders and inflammatory diseases, such as rheumatoid arthritis, multiple sclerosis, systemic lupus erythematosus or vasculitic conditions. It may further include allergic diseases, airway diseases, such as asthma and chronic obstructive pulmonary disease (COPD) or conditions caused by delayed or immediate type hypersensitivity and anaphylaxis, acute or chronic transplant rejection or graft versus host disease, cancers of hematopoietic origin or solid tumors, including chronic myelogenous leukemia, myeloid leukemia, non-Hodgkin lymphoma and other B cell lymphomas.

More particularly, in embodiment 1 the present invention provides a compound of formula (I) or a pharmaceutically acceptable salt thereof;

As used herein, the terms "salt" or "salts" refers to an acid addition or base addition salt of a compound of the invention. "Salts" include in particular "pharmaceutically acceptable salts". The term "pharmaceutically acceptable salts" refers to salts that retain the biological effectiveness and properties of the compounds of this invention and, which typically are not biologically or otherwise undesirable. In many cases, the compounds of the present invention are capable of forming acid and/or base salts by virtue of the presence of amino and/or carboxyl groups or groups similar thereto.

The pharmaceutically acceptable salts of the present invention can be synthesized from a basic or acidic moiety, by conventional chemical methods. Generally, such salts can be prepared by reacting free acid forms of these compounds with a stoichiometric amount of the appropriate base (such as Na, Ca, Mg, or K hydroxide, carbonate, bicarbonate or the like), or by reacting free base forms of these compounds with a stoichiometric amount of the appropriate acid. Such reactions are typically carried out in water or in an organic solvent, or in a mixture of the two. Generally, use of non-aqueous media like ether, ethyl acetate, ethanol, isopropanol, or acetonitrile is desirable, where practicable. Lists of additional suitable salts can be found, *e.g.*, in "Remington's Pharmaceutical Sciences", 20th ed., Mack Publishing Company, Easton, Pa., (1985); and in "Handbook of Pharmaceutical Salts: Properties, Selection, and Use" by Stahl and Wermuth (Wiley-VCH, Weinheim, Germany, 2002).

Any formula given herein is also intended to represent unlabeled forms as well as isotopically labeled forms of the compounds. Isotopically labeled compounds have structures depicted by the formulas given herein except that one or more atoms are replaced by an atom having a selected atomic mass or mass number. Examples of isotopes that can be incorporated into compounds of the invention include isotopes of hydrogen, carbon, nitrogen, oxygen, phosphorous, fluorine, and chlorine, such as ^2H , ^3H , ^{11}C , ^{13}C , ^{14}C , ^{15}N , ^{18}F , ^{31}P , ^{32}P , ^{35}S , ^{36}Cl , ^{125}I respectively. The invention includes various isotopically labeled compounds as defined herein, for example those into which radioactive isotopes, such as ^3H and ^{14}C , or those into which non-radioactive isotopes, such as ^2H and ^{13}C are present. Such isotopically labeled compounds are useful in metabolic studies (with ^{14}C), reaction kinetic studies (with, for example ^2H or ^3H), detection or imaging techniques, such as positron emission tomography (PET) or single-

photon emission computed tomography (SPECT) including drug or substrate tissue distribution assays, or in radioactive treatment of patients. In particular, an ^{18}F or labeled compound may be particularly desirable for PET or SPECT studies. Isotopically-labeled compounds of formula (I) can generally be prepared by conventional techniques known to those skilled in the art or by processes analogous to those described in the accompanying Examples and Preparations using an appropriate isotopically-labeled reagents in place of the non-labeled reagent previously employed.

Further, substitution with heavier isotopes, particularly deuterium (i.e., ^2H or D) may afford certain therapeutic advantages resulting from greater metabolic stability, for example increased in vivo half-life or reduced dosage requirements or an improvement in therapeutic index. It is understood that deuterium in this context is regarded as a substituent of a compound of the formula (I). The concentration of such a heavier isotope, specifically deuterium, may be defined by the isotopic enrichment factor. The term "isotopic enrichment factor" as used herein means the ratio between the isotopic abundance and the natural abundance of a specified isotope. If a substituent in a compound of this invention is denoted deuterium, such compound has an isotopic enrichment factor for each designated deuterium atom of at least 3500 (52.5% deuterium incorporation at each designated deuterium atom), at least 4000 (60% deuterium incorporation), at least 4500 (67.5% deuterium incorporation), at least 5000 (75% deuterium incorporation), at least 5500 (82.5% deuterium incorporation), at least 6000 (90% deuterium incorporation), at least 6333.3 (95% deuterium incorporation), at least 6466.7 (97% deuterium incorporation), at least 6600 (99% deuterium incorporation), or at least 6633.3 (99.5% deuterium incorporation).

Pharmaceutically acceptable solvates in accordance with the invention include those wherein the solvent of crystallization may be isotopically substituted, e.g. D_2O , d_6 -acetone, d_6 -DMSO.

Compounds of the invention, i.e. compounds of formula (I) that contain groups capable of acting as donors and/or acceptors for hydrogen bonds may be capable of forming co-crystals with suitable co-crystal formers. These co-crystals may be prepared from compounds of formula (I) by known co-crystal forming procedures. Such procedures include grinding, heating, co-subliming, co-melting, or contacting in solution compounds

of formula (I) with the co-crystal former under crystallization conditions and isolating co-crystals thereby formed. Suitable co-crystal formers include those described in WO 2004/078163. Hence the invention further provides co-crystals comprising a compound of formula (I).

Mack Printing Company, 1990, pp. 1289-1329). Except insofar as any conventional carrier is incompatible with the active ingredient, its use in the therapeutic or pharmaceutical compositions is contemplated.

The term "a therapeutically effective amount" of a compound of the present invention refers to an amount of the compound of the present invention that will elicit the biological or medical response of a subject, for example, reduction or inhibition of an enzyme or a protein activity, or ameliorate symptoms, alleviate conditions, slow or delay disease progression, or prevent a disease, etc. In one non-limiting embodiment, the term "a therapeutically effective amount" refers to the amount of the compound of the present invention that, when administered to a subject, is effective to (1) at least partially alleviating, inhibiting, preventing and/or ameliorating a condition, or a disorder or a disease (i) mediated by MALT1, or (ii) associated with MALT1 activity, or (iii) characterized by activity (normal or abnormal) of MALT1; or (2) reducing or inhibiting the activity of MALT1; or (3) reducing or inhibiting the expression of MALT1; or (4) modifying the protein levels of MALT1. In another non-limiting embodiment, the term "a therapeutically effective amount" refers to the amount of the compound of the present invention that, when administered to a cell, or a tissue, or a non-cellular biological material, or a medium, is effective to at least partially reducing or inhibiting the activity of MALT1; or reducing or inhibiting the expression of MALT1 partially or completely.

As used herein, the term "subject" refers to an animal. Typically the animal is a mammal. A subject also refers to for example, primates (*e.g.*, humans, male or female),

cows, sheep, goats, horses, dogs, cats, rabbits, rats, mice, fish, birds and the like. In certain embodiments, the subject is a primate. In yet other embodiments, the subject is a human.

As used herein, the term "inhibit", "inhibition" or "inhibiting" refers to the reduction or suppression of a given condition, symptom, or disorder, or disease, or a significant decrease in the baseline activity of a biological activity or process.

As used herein, the term "treat", "treating" or "treatment" of any disease or disorder refers in one embodiment, to ameliorating the disease or disorder (i.e., slowing or arresting or reducing the development of the disease or at least one of the clinical symptoms thereof). In another embodiment "treat", "treating" or "treatment" refers to alleviating or ameliorating at least one physical parameter including those which may not be discernible by the patient. In yet another embodiment, "treat", "treating" or "treatment" refers to modulating the disease or disorder, either physically, (e.g., stabilization of a discernible symptom), physiologically, (e.g., stabilization of a physical parameter), or both. In yet another embodiment, "treat", "treating" or "treatment" refers to preventing or delaying the onset or development or progression of the disease or disorder.

As used herein, a subject is "in need of" a treatment if such subject would benefit biologically, medically or in quality of life from such treatment.

As used herein, the term "a," "an," "the" and similar terms used in the context of the present invention (especially in the context of the claims) are to be construed to cover both the singular and plural unless otherwise indicated herein or clearly contradicted by the context.

All methods described herein can be performed in any suitable order unless otherwise indicated herein or otherwise clearly contradicted by context. The use of any and all examples, or exemplary language (e.g. "such as") provided herein is intended merely to better illuminate the invention and does not pose a limitation on the scope of the invention otherwise claimed.

Any asymmetric atom (e.g., carbon or the like) of the compound(s) of the present invention can be present in racemic or enantiomerically enriched, for example the (*R*)-,

(*S*)- or (*R,S*)- configuration. In certain embodiments, each asymmetric atom has at least 50% enantiomeric excess, at least 60% enantiomeric excess, at least 70% enantiomeric excess, at least 80% enantiomeric excess, at least 90% enantiomeric excess, at least 95% enantiomeric excess, or at least 99% enantiomeric excess in the (*R*)- or (*S*)- configuration. Substituents at atoms with unsaturated double bonds may, if possible, be present in *cis*- (*Z*)- or *trans*- (*E*)- form.

Accordingly, as used herein a compound of the present invention can be in the form of one of the possible isomers, rotamers, atropisomers, tautomers or mixtures thereof, for example, as substantially pure geometric (*cis* or *trans*) isomers, diastereomers, optical isomers (antipodes), racemates or mixtures thereof.

Any resulting mixtures of isomers can be separated on the basis of the physicochemical differences of the constituents, into the pure or substantially pure geometric or optical isomers, diastereomers, racemates, for example, by chromatography and/or fractional crystallization.

Any resulting racemates of final products or intermediates can be resolved into the optical antipodes by known methods, *e.g.*, by separation of the diastereomeric salts thereof, obtained with an optically active acid or base, and liberating the optically active acidic or basic compound. In particular, a basic moiety may thus be employed to resolve the compounds of the present invention into their optical antipodes, *e.g.*, by fractional crystallization of a salt formed with an optically active acid, *e.g.*, tartaric acid, dibenzoyl tartaric acid, diacetyl tartaric acid, di-*O,O'*-*p*-toluoyl tartaric acid, mandelic acid, malic acid or camphor-10-sulfonic acid. Racemic products can also be resolved by chiral chromatography, *e.g.*, high pressure liquid chromatography (HPLC) using a chiral stationary phase.

Furthermore, the compounds of the present invention, including their salts, can also be obtained in the form of their hydrates, or include other solvents used for their crystallization. The compounds of the present invention may inherently or by design form solvates with pharmaceutically acceptable solvents (including water); therefore, it is intended that the invention embrace both solvated and unsolvated forms. The term "solvate" refers to a molecular complex of a compound of the present invention (including pharmaceutically acceptable salts thereof) with one or more solvent

molecules. Such solvent molecules are those commonly used in the pharmaceutical art, which are known to be innocuous to the recipient, *e.g.*, water, ethanol, and the like. The term "hydrate" refers to the complex where the solvent molecule is water.

The compounds of the present invention, including salts, hydrates and solvates thereof, may inherently or by design form polymorphs.

In another aspect, the present invention provides a pharmaceutical composition comprising a compound of the present invention and a pharmaceutically acceptable carrier. The pharmaceutical composition can be formulated for particular routes of administration such as oral administration, parenteral administration, and rectal administration, etc. In addition, the pharmaceutical compositions of the present invention can be made up in a solid form (including without limitation capsules, tablets, pills, granules, powders or suppositories), or in a liquid form (including without limitation solutions, suspensions or emulsions). The pharmaceutical compositions can be subjected to conventional pharmaceutical operations such as sterilization and/or can contain conventional inert diluents, lubricating agents, or buffering agents, as well as adjuvants, such as preservatives, stabilizers, wetting agents, emulsifiers and buffers, etc.

Typically, the pharmaceutical compositions are tablets or gelatin capsules comprising the active ingredient together with

- a) diluents, *e.g.*, lactose, dextrose, sucrose, mannitol, sorbitol, cellulose and/or glycine;
- b) lubricants, *e.g.*, silica, talcum, stearic acid, its magnesium or calcium salt and/or polyethyleneglycol; for tablets also
- c) binders, *e.g.*, magnesium aluminum silicate, starch paste, gelatin, tragacanth, methylcellulose, sodium carboxymethylcellulose and/or polyvinylpyrrolidone; if desired
- d) disintegrants, *e.g.*, starches, agar, alginic acid or its sodium salt, or effervescent mixtures; and/or
- e) absorbents, colorants, flavors and sweeteners.

Tablets may be either film coated or enteric coated according to methods known in the art.

Suitable compositions for oral administration include an effective amount of a compound of the invention in the form of tablets, lozenges, aqueous or oily suspensions, dispersible powders or granules, emulsion, hard or soft capsules, or syrups or elixirs. Compositions intended for oral use are prepared according to any method known in the art for the manufacture of pharmaceutical compositions and such compositions can contain one or more agents selected from the group consisting of sweetening agents, flavoring agents, coloring agents and preserving agents in order to provide pharmaceutically elegant and palatable preparations. Tablets may contain the active ingredient in admixture with nontoxic pharmaceutically acceptable excipients which are suitable for the manufacture of tablets. These excipients are, for example, inert diluents, such as calcium carbonate, sodium carbonate, lactose, calcium phosphate or sodium phosphate; granulating and disintegrating agents, for example, corn starch, or alginic acid; binding agents, for example, starch, gelatin or acacia; and lubricating agents, for example magnesium stearate, stearic acid or talc. The tablets are uncoated or coated by known techniques to delay disintegration and absorption in the gastrointestinal tract and thereby provide a sustained action over a longer period. For example, a time delay material such as glyceryl monostearate or glyceryl distearate can be employed. Formulations for oral use can be presented as hard gelatin capsules wherein the active ingredient is mixed with an inert solid diluent, for example, calcium carbonate, calcium phosphate or kaolin, or as soft gelatin capsules wherein the active ingredient is mixed with water or an oil medium, for example, peanut oil, liquid paraffin or olive oil.

Certain injectable compositions are aqueous isotonic solutions or suspensions, and suppositories are advantageously prepared from fatty emulsions or suspensions. Said compositions may be sterilized and/or contain adjuvants, such as preserving, stabilizing, wetting or emulsifying agents, solution promoters, salts for regulating the osmotic pressure and/or buffers. In addition, they may also contain other therapeutically valuable substances. Said compositions are prepared according to conventional mixing, granulating or coating methods, respectively, and contain about 0.1-75%, or contain about 1-50%, of the active ingredient.

Suitable compositions for transdermal application include an effective amount of a compound of the invention with a suitable carrier. Carriers suitable for transdermal delivery include absorbable pharmacologically acceptable solvents to assist passage through the skin of the host. For example, transdermal devices are in the form of a bandage comprising a backing member, a reservoir containing the compound optionally with carriers, optionally a rate controlling barrier to deliver the compound of the skin of the host at a controlled and predetermined rate over a prolonged period of time, and means to secure the device to the skin.

Suitable compositions for topical application, *e.g.*, to the skin and eyes, include aqueous solutions, suspensions, ointments, creams, gels or sprayable formulations, *e.g.*, for delivery by aerosol or the like. Such topical delivery systems will in particular be appropriate for dermal application, *e.g.*, for the treatment of skin cancer, *e.g.*, for prophylactic use in sun creams, lotions, sprays and the like. They are thus particularly suited for use in topical, including cosmetic, formulations well-known in the art. Such may contain solubilizers, stabilizers, tonicity enhancing agents, buffers and preservatives.

As used herein a topical application may also pertain to an inhalation or to an intranasal application. They may be conveniently delivered in the form of a dry powder (either alone, as a mixture, for example a dry blend with lactose, or a mixed component particle, for example with phospholipids) from a dry powder inhaler or an aerosol spray presentation from a pressurised container, pump, spray, atomizer or nebuliser, with or without the use of a suitable propellant.

The present invention further provides anhydrous pharmaceutical compositions and dosage forms comprising the compounds of the present invention as active ingredients, since water may facilitate the degradation of certain compounds.

Anhydrous pharmaceutical compositions and dosage forms of the invention can be prepared using anhydrous or low moisture containing ingredients and low moisture or low humidity conditions. An anhydrous pharmaceutical composition may be prepared and stored such that its anhydrous nature is maintained. Accordingly, anhydrous compositions are packaged using materials known to prevent exposure to water such that they can be included in suitable formulary kits. Examples of suitable packaging

include, but are not limited to, hermetically sealed foils, plastics, unit dose containers (e.g., vials), blister packs, and strip packs.

The invention further provides pharmaceutical compositions and dosage forms that comprise one or more agents that reduce the rate by which the compound of the present invention as an active ingredient will decompose. Such agents, which are referred to herein as "stabilizers," include, but are not limited to, antioxidants such as ascorbic acid, pH buffers, or salt buffers, etc.

Synthesis of the compounds of the present invention

The synthesis of the compounds of the invention is performed as outlined in Scheme 1:

(Scheme 1)

Treatment of an activated acid, e.g. activated as an imidazolid, with the dianion of a malonate mono-ester provides after workup β -ketoester 2. Condensation with a C1 equivalent, e.g. dimethylformamide-dimethylacetal or triethyl orthoformate, followed by

cyclo-condensation with aminopyrazoles in an organic solvent like ethanol at elevated temperature provides the substituted pyrazolo-pyrimidines 3. In case a chiral acid is used in step 1, depending on the substitution pattern, partial racemization may occur during the reaction sequence. In this case the final product may be purified to high enantiomeric purity by chiral chromatography typically as shown for example 119.

Deprotection of the ester provides acid 4. Curtius rearrangement of acid 4 provides an intermediate isocyanate which may be reacted with an appropriate aniline or aminopyridine in a one pot reaction to form the final products.

The synthesis of aminopyrazoles, like 3-amino-5-chloropyrazole can be conducted as follows (Scheme 2):

(Scheme 2)

Treatment of aminopyrazole under Sandmeyer conditions provides 3-chloropyrazole. Nitration provides the N-nitropyrazole, which upon heating rearranges to the desired 3-chloro-5-nitropyrazole. Reduction of the nitro group, using iron, tin or tin chloride finally provides the desired 3-amino-5-chloropyrazole 10.

Anilines and aminopyridines used in this invention can be prepared using the following route:

(Scheme 3)

A substituted para-nitro-chlorobenzene or p-nitrochloropyridine is treated with a nucleophile in an inert solvent like DMF, to give the substitution product **12**. The nucleophile in this case can be deprotonated alcohols, amines, lactams or heterocycles, e.g. the anion of 1,2,3 triazole. Finally reduction of the nitro substituent using tin or iron in acidic media provides the desired aminophenyl- or aminopyridyl-derivatives **13**.

Alternatively, anilines or aminopyridines can be prepared via Curtius rearrangement of suitable aryl acids (Scheme 4):

(Scheme 4)

Treatment of acid **14** with diphenyl phosphoryl azide and base in t-butanol provides the t-butoxy-carbonyl-protected amino compound **15**, which can be deprotected under acidic conditions using HCl or TFA to give the desired aniline/aminopyridine **16**.

Certain aminopyridines and anilines can be prepared by palladium-catalyzed coupling of an aryl halide with a boronic acid according to Scheme 5:

(Scheme 5)

Pyridones of this invention are generally prepared via alkylation of hydroxypyridines (Scheme 6):

(Scheme 6)

Treatment of a hydroxypyridine 19 with base, e.g. potassium carbonate and an alkylhalide leads to the formation of the pyridone 20 and the alkoxy-pyridine 22. Depending on the substitution pattern of the reactants selectivity towards one or the other reaction product can be achieved. After separation of the products, each compound can be reduced using standard iron or tin mediated reduction methods to provide the aminopyridones 21, as well as the amino-alkoxy-pyridines 23.

Biological / Pharmacological Section

The compounds of the invention exhibit valuable pharmacological properties, e.g. properties susceptible to MALT1, for example the inhibition of MALT1 proteolytic and/or autoproteolytic activity e.g. as indicated in the test assays provided infra and are therefore indicated for therapy.

Assays:

MALT1 biochemical assay:

IC₅₀ values of test compounds were determined with an enzyme activity assay using the C-domain of MALT1 (amino acids 329-824). The readout parameter is the increase of fluorescence lifetime over time, proportional to enzyme activity.

The assay employs a short peptide substrate labeled with the single fluorophore PT14 as a fluorescence lifetime probe sensitive to the cleavage state of the substrate (PT14: 6-(9-oxo-9H-acridin-10-yl)-hexanoate, AssayMetrics, UK). The peptide substrate has the following sequence: Ac-Trp-Leu-Arg-Ser-Arg[^]Cys(PT14)-NH₂ (Product number BS-9117, Biosyntan, Germany, N-terminus to C-terminus from left to right in three letter code, Ac: acetyl group, Cys(PT14): cysteine residue with the fluorophore PT14 conjugated to the cysteine sulfhydryl group via a maleimide group; C-terminus of the peptide is amidated; within the substrate sequence written above, [^] indicates the scissile bond). The assay buffer consists of 200 mM Tris/HCl at pH 7.5, 0.8 M Na citrate, 100 μ M EGTA, 100 μ M DTT and 0.05 % (w/v) CHAPS. The kinetic characterization of the enzymatic reaction led

to the determination of a Michaelis Constant (K_M) of 40 μM and a k_{cat} value of 34 s^{-1} . The assay was established for the 384-well plate format using black microtiter round well plates (Product number 95040020, Thermo Electron Oy, Finland). Test compounds were dissolved in 100% (v/v) DMSO or a mixture containing 90% (v/v) DMSO and 10% (v/v) H₂O at a stock concentration of 100 mM. Serial dilutions of test compounds were prepared using either 100% (v/v) DMSO or a mixture containing 90% (v/v) DMSO and 10% (v/v) H₂O.

For the measurement of compound inhibition, 0.25 μl of test compound were mixed with 12.5 μl of enzyme in wells of the 384-well plates, and incubated for 60 minutes at room temperature (22 °C). After that, 12.5 μl of substrate was added, and the enzymatic reaction was allowed to proceed for 60 minutes at room temperature (22 °C). The total assay volume was 25.25 μl , and the final assay concentrations for enzyme and substrate were 2.5 nM and 1 μM , respectively. The increase in assay signal over time is linear for at least 60 minutes at the assay conditions reported, and directly proportional to the concentration of active enzyme up to at least 2.5 nM. The DMSO content was between 0.9 and 1% (v/v). The final assay concentrations of the test compounds ranged typically from 100 μM to 1 nM in a serial dilution series using a dilution factor of 3.16 (i.e. half-logarithmic dilution steps). As controls, reactions were performed in multiple wells either by only adding DMSO instead of test compound, leading to an uninhibited enzymatic reaction (i.e. 0% inhibition), or by adding assay buffer without enzyme mixed with DMSO, which is the equivalent of a fully inhibited reaction (i.e. 100% inhibition). The fluorescence lifetimes were recorded using a microtiter plate reader such as the TECAN Ultra Evolution FLT instrument with fluorescence excitation at 405 nm and emission recording at 450 nm. The fluorescence lifetimes can be transformed to percentage inhibitions using the above mentioned controls as reference (for 0 and 100% inhibition). The IC₅₀ value was calculated from the plot of percentage inhibition versus inhibitor concentration using non-linear regression analysis software (Origin, OriginLab Corporation, USA). The data were fitted using a 4 Parameter Logistic Model, characterized by the following equation:

$$y = A_2 + (A_1 - A_2) / (1 + (x / \text{IC}_{50})^p)$$

where y is the %-inhibition at the inhibitor concentration, x. A₁ is the lowest inhibition value, and A₂ the maximum inhibition value. The exponent, p, is the Hill coefficient.

clAP2-MALT1-driven NFkappaB reporter gene assay (RGA) in HEK293

The fusion protein clAP2-MALT1 is driving constitutive NF- κ B activation in the MALT-type of B cell lymphoma. To monitor the activity of MALT1 inhibitors on NF- κ B signaling, a mechanistic model was established consisting of a stably transfected HEK293 cell line in which the activated clAP2-MALT1 fusion protein is constitutively expressed and the firefly luciferase reporter gene is under the control of NF- κ B response elements. Inhibition of luciferase gene expression is measured using a luciferase activity detection assay. Briefly, 1.8×10^4 cells/90 μl /well are seeded in a sterile, white-walled, clear-bottom tissue-culture-treated 96-well microplates (Costar, Cat-No 3903). After overnight

incubation at 37 °C, 10 µL of 10x 3-fold serial compound dilutions prepared initially in DMSO, followed by a 1:100 intermediated dilution in cell culture medium, is added to the cells using liquid handling robotics (Velocity Bravo 11, Agilent). Unless otherwise mentioned, compound start concentration is 10µM and the final vehicle concentration is 0.1% DMSO in all wells. After 24h compound incubation, cell viability is assessed in a first step 3 hrs following addition of 10 µl 135 µg/ml resazurin sodium salt (SIGMA Cat-Nr R7017) dissolved in phosphate-buffered saline. Following quantification of reduced resazurin at excitation/emission wavelengths of 540/590nm on a multipurpose microplate reader (e.g. Infinite M200Pro, TECAN), cells are subjected to quantification of luciferase expression levels following incubation with 70 µL ONEGlow (Promega, Cat-Nr E6120) homogenous assay buffer for 20 min at room temperature. Light emission is recorded on a multipurpose microplate reader (e.g. Infinite M200Pro, TECAN) in luminescence detection mode. Raw data are processed using an Excel analysis template. The effect of a particular test compound concentration on NF-kB activity is expressed as luciferase signal (Relative Light Units) normalized to cell viability by means of division with the reduced resazurin signal (Relative Fluorescence Units). The value obtained for vehicle-treated cells is set as 100%. Absolute (50% reduction relative to vehicle control) and relative (inflection point) IC50 values (µM) are determined using 4-parametric curve-fitting (XLfit, V4.3.2). In addition, % normalized NF-kB signal and % cell viability at the highest compound concentration tested.

Human IL2 promoter reporter gene assay (RGA) in Jurkat cells

The transfected Jurkat clone K22 290_H23 was propagated in RPMI 1640 supplemented with 10 % heat inactivated fetal calf serum, 50 µM 2-mercaptoethanol and 1 mg/ml Geneticin. The cell concentration should not exceed 1 x 10⁶ /ml during culturing. The cells should not exceed passage 30. Prior to the assay the cells were washed and prepared to the concentration of 2 x 10⁶ cells /ml.

Compound dilutions were made as 2 x-concentrated solutions then diluted ½ by addition to cells. Two hundred and fifty µl of compound dilution and 250 µl of cells were mixed together in wells of a 96-deep well plate. Cells / compounds premix were incubated 30 min at 37 °C and 5 % CO₂ directly in the deep well plate.

After pre-incubation of cells with compounds, cells were stimulated with anti-CD28 mAb (clone 15E8) at 3 µg/ml + PMA at 1 µg/ml. Both co-stimulants were diluted in culture medium at a 10 x-concentrated solution. 10 µl of co-stimulants were pipetted into the white 96-well plates and 100 µl of cell/compound mix was immediately added in duplicates. The cells were stimulated for 5.5 h at 37 °C and 5 % CO₂.

After cell stimulation, 50 µl of BriteLitePlus reagent (Perkin Elmer) was added to each well and the bioluminescence was measured with a Wallac EnVision reader (Perkin Elmer).
