

MODIFIED BLACK OIL MODEL FOR CALCULATING MIXING OF DIFFERENT FLUIDS IN A COMMON SURFACE NETWORK

CROSS-REFERENCE TO RELATED APPLICATIONS

The present application claims the benefit of U.S. Provisional Patent Application
5 No. 61/951,819, filed on March 12, 2014, titled "Procedure for Using a Modified Black Oil Model for Calculating Mixing of Different Fluids in a Common Surface Network," which is incorporated herein by reference in its entirety.

FIELD OF THE DISCLOSURE

The present disclosure relates generally to the recovery of subterranean deposits and
10 more specifically to the recovery of subterranean hydrocarbon deposits from multiple reservoirs through a common surface network.

BACKGROUND

When multiple reservoirs are produced through a common facility network, the capability to integrate the modeling of surface and subsurface can be critical to field
15 development and optimization. The shared facility network imposes constraints that the combined production cannot exceed, determines the pressure drop in the flow lines, and the composition and volume of the sales and reinjection streams. Pressure drop in flow lines is particularly important in deepwater field development, where flow lines are long, and production from multiple reservoirs can flow through the same riser.

Often, the fluid characterizations of these reservoirs have been derived
20 independently. In each case, the appropriate fluid representation was selected that provided an optimum combination of accuracy and computational efficiency. The two most common fluid characterizations are the equation of state (EOS) model and the black oil model. Examples of common EOS models in the industry include the Peng-Robinson EOS
25 (Peng, Robinson, 1976) and the Soave-Redlich-Kwong EOS (Soave, 1972).

A hydrocarbon fluid may actually be composed of hundreds of distinct components. When modeling using an EOS, the engineer must specify the number of pseudo-components (typically 5 to 12) and their EOS properties. Pseudo-components are combinations of actual components. Alternatively, black-oil modeling involves
30 specification of a number of common engineering measurements in tables that vary with

pressure. However, it is inherently a model with two pseudo-components. The net result is that the different connected reservoirs are being modeled with a variable number of pseudo-components, some of which may be common. However, even the common pseudo-components may have different fluid properties in the different reservoirs.

5 Several examples have been presented in the literature, including from Ghorayeb et al. in 2003 and Ghorayeb and Holmes in 2005, for various approaches in which the black oil models are first converted to a common compositional model and then an EOS is used to calculate the fluid properties. However, these approach lead to an EOS model with a large number of components that is extremely computationally expensive to solve.

BRIEF DESCRIPTION OF THE DRAWINGS

10 Illustrative embodiments of the present disclosure are described in detail below with reference to the attached drawing figures.

15 FIGS. 1A and 1B illustrate examples of production wells suitable for hydrocarbon production and exploration from a subsurface reservoir.

 FIG. 2 is a block diagram of an exemplary system for simulating fluid production in a multi-reservoir system with a common surface network.

 FIG. 3 is a diagram illustrating an exemplary of a multi-reservoir system with a common surface network.

20 FIG. 4A is a flowchart of an exemplary method of generating a modified black oil model to simulate fluid production in a multi-reservoir system with a common surface network.

 FIG. 4B is a flowchart of an exemplary method of using a modified black oil model to simulate fluid production in a multi-reservoir system with a common surface network.

25 FIG. 5 is a block diagram of an exemplary computer system in which embodiments of the present disclosure may be implemented.

 The illustrated figures are only exemplary and are not intended to assert or imply any limitation with regard to the environment, architecture, design, or process in which different embodiments may be implemented.

DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS

Embodiments of the present disclosure relate to using a modified black oil model to simulate fluid production in a multi-reservoir system with a common surface network. While the present disclosure is described herein with reference to illustrative embodiments for particular applications, it should be understood that embodiments are not limited thereto. The description of the present disclosure has been presented for purposes of illustration and description, but is not intended to be exhaustive or limited to the embodiments in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in the art without departing from the scope and spirit of the disclosure. The illustrative embodiments described herein are provided to explain the principles of the disclosure and the practical application thereof, and to enable others of ordinary skill in the art to understand that the disclosed embodiments may be modified as desired for a particular implementation or use. The scope of the claims is intended to broadly cover the disclosed embodiments and any such modification. Any actual data values listed in the detailed description are provided for illustrative purposes only and embodiments of the present disclosure are not intended to be limited thereto. Thus, the operational behavior of embodiments will be described with the understanding that modifications and variations of the embodiments are possible, given the level of detail presented herein.

In the detailed description herein, references to “one embodiment,” “an embodiment,” “an example embodiment,” etc., indicate that the embodiment described may include a particular feature, structure, or characteristic, but every embodiment may not necessarily include the particular feature, structure, or characteristic. Moreover, such phrases are not necessarily referring to the same embodiment. Further, when a particular feature, structure, or characteristic is described in connection with an embodiment, it is submitted that it is within the knowledge of one skilled in the art to implement such feature, structure, or characteristic in connection with other embodiments whether or not explicitly described.

As used herein, the singular forms “a,” “an” and “the” are intended to include the plural forms as well, unless the context clearly indicates otherwise. It will be further understood that the terms “comprise” and/or “comprising,” when used in this specification and/or the claims, specify the presence of stated features, integers, steps, operations,

elements, and/or components, but do not preclude the presence or addition of one or more other features, integers, steps, operations, elements, components, and/or groups thereof. The corresponding structures, materials, acts, and equivalents of all means or step plus function elements in the claims below are intended to include any structure, material, or act for performing the function in combination with other claimed elements as specifically claimed.

The disclosed embodiments and advantages thereof are best understood by referring to the drawings, in which like numerals are used for like and corresponding parts of the various drawings. Other features and advantages of the disclosed embodiments will be or will become apparent to one of ordinary skill in the art upon examination of the following figures and detailed description. It is intended that all such additional features and advantages be included within the scope of the disclosed embodiments. Further, the illustrated figures are only exemplary and are not intended to assert or imply any limitation with regard to the environment, architecture, design, or process in which different embodiments may be implemented.

The disclosed embodiments relate to providing a modified black oil model of reservoir fluids to simulate fluid production in a multi-reservoir system with a common surface network. As will be described in further detail below, reservoir fluids from multiple hydrocarbon reservoirs may be produced through a common gathering point or shared facility of the common surface network. Thus, heterogeneous fluids from different reservoirs that flow into the common gathering point may combine or mix together.

In one example, fluid production through the common surface network in such a multi-reservoir system may be simulated using a black oil representation of reservoir fluids. During a simulation of fluid production using such a black oil model, fluid properties may be determined from black oil tables with measurements of reservoir fluid pressure relative to commonly measured laboratory quantities of reservoir fluid parameters. Examples of such fluid parameters include, but are not limited to, an oil formation volume factor and a solution gas-to-oil ratio. In some implementations, the black oil model may be transformed into a multi-component compositional model of reservoir fluids. The multi-component compositional model may then be used during the simulation in this example to determine the properties of mixed fluids with different components that have been combined from multiple reservoir fluids produced through the common gathering point of the common

surface network. The properties of the multi-component fluid may be calculated using, for example, a cubic equation of state model (EOS). One example of a reservoir simulator in which such a compositional model described herein may be used is the Nexus® reservoir simulator available from Landmark Graphics Corporation of Houston, Texas.

5 As will be described in further detail below, the multi-reservoir fluid simulation techniques disclosed herein may use the multi-component compositional model as the basis for determining mixed fluid properties. In an embodiment, a modified black oil model may be provided for determining fluid properties at different points in the common surface network during a simulation of fluid production in a multi-reservoir system. The
10 simulation may be based in part on production system data including various measurements collected downhole from a well drilled within each hydrocarbon reservoir, e.g., in the form of a production well for an oil and gas reservoir. Further, multiple production wells may be drilled for providing access to the reservoir fluids underground. Measured well data may be collected regularly from each production well to track changing conditions in the
15 reservoir, as will be described in further detail below with respect to the production well examples illustrated in FIGS. 1A and 1B.

FIGS. 1A is a diagram of an exemplary production well 100A with a borehole 102 that has been drilled into a reservoir formation. Borehole 102 may be drilled to any depth and in any direction within the formation. For example, borehole 102 may be drilled to ten
20 thousand feet or more in depth and further, may be steered horizontally for any distance through the formation, as desired for a particular implementation. The production well 100A also includes a casing header 104 and a casing 106, both secured into place by cement 103. A blowout preventer (BOP) 108 couples to casing header 104 and a production wellhead 110, which together seal in the well head and enable fluids to be
25 extracted from the well in a safe and controlled manner.

Measured well data may be periodically sampled and collected from the production well 100A and combined with measurements from other wells within a reservoir, enabling the overall state of the reservoir to be monitored and assessed. These measurements may be taken using a number of different downhole and surface instruments, including but not
30 limited to, a temperature and pressure sensor 118 and a flow meter 120. Additional devices may also be coupled in-line to a production tubing 112 including, for example, a downhole choke 116 (e.g., for varying a level of fluid flow restriction), an electric submersible pump

(ESP) 122 (e.g., for drawing in fluid flowing from perforations 125 outside ESP 122 and production tubing 112), an ESP motor 124 (e.g., for driving ESP 122), and a packer 114 (e.g., for isolating the production zone below the packer from the rest of well 100A). Additional surface measurement devices may be used to measure, for example, the tubing head pressure and the electrical power consumption of ESP motor 124.

FIG. 1B is a diagram showing an alternative embodiment of the production well 100A of FIG. 1A, which includes many of the same components as well 100A but has been adapted for artificial gas lift. As shown in FIG. 1B, a production well 100B further includes a gas lift injector mandrel 126 in addition to the above-described components of well 100A. In an embodiment, gas lift injector mandrel 126 is coupled in-line with production tubing 112 for controlling a flow of injected gas into a portion of production tubing 112 located above-ground or at the surface of the well near wellhead 110. Although not shown in FIG. 1B, the gas lift production well 100B may also include the same type of downhole and surface instruments as shown for production well 100A in FIG. 1A for providing the above-described measurements.

As shown in FIGS. 1A and 1B, each of the devices along production tubing 112 couples to a cable 128, which may be attached to an exterior portion of production tubing 112. Cable 128 may be used primarily to provide power to the devices to which it couples. Cable 128 also may be used to provide signal paths (e.g., electrical or optical paths), through which control signals may be directed from the surface to the downhole devices as well as telemetry signals from the downhole devices to the surface. The respective control and telemetry signals may be sent and received by a control unit 132 at the surface of the production well. Control unit 132 may be coupled to cable 128 through blowout preventer 108. In an embodiment, field personnel may use control unit 132 to control and monitor the downhole devices locally, e.g., via a user interface provided at a terminal or control panel integrated with control unit 132. Additionally or alternatively, the downhole devices may be controlled and monitored by a remote processing system 140. Processing system 140 may be used to provide various supervisory control and data acquisition (SCADA) functionality for the production wells associated with each reservoir in a field. For example, a remote operator may use processing system 140 to send appropriate commands for controlling wellsite operations to control unit 132. Communication between control unit 132 and processing system 140 may be via one or more communication networks, e.g.,

in the form of a wireless network (e.g., a cellular network), a wired network (e.g., a cabled connection to the Internet) or a combination of wireless and wired networks.

As shown in FIGS. 1A and 1B, processing system 140 may include a computing device 142 (e.g., a server) and a data storage device 144 (e.g., a database). Although only one computing device and one data storage device are shown in FIGS. 1A and 1B, it should be appreciated that processing system 140 may include additional computing devices and data storage devices. Computing device 142 may be implemented using any type of computing device having at least one processor, a memory and a networking interface capable of sending and receiving data to and from control unit 132 via a communication network. In an embodiment, computing device 142 may be a type of server. Examples of such a server include, but are not limited to, a web server, an application server, a proxy server, and a network server. In some implementations, computing device 142 may represent a group of computing devices in a server farm.

In an embodiment, control unit 132 may periodically send wellsite production data via a communication network to processing system 140 for processing and storage. Such wellsite production data may include, for example, production system measurements from various downhole devices, as described above. In some implementations, such production data may be sent using a remote terminal unit (RTU) of control unit 132. In an embodiment, data storage device 144 may be used to store the production data received from control unit 132. In an example, data storage device 144 may be used to store historical production data including a record of actual and simulated production system measurements obtained or calculated over a period of time, e.g., multiple simulation time-steps, as will be described in further detail below.

While production wells 100A and 100B are described in the context of a single reservoir, it should be noted that the embodiments disclosed herein are not limited thereto and that the disclosed embodiments may be applied to fluid production from multiple reservoirs in a multi-reservoir production system with a common surface or gathering network, as will be described in further detail below with respect to FIG. 3. Thus, a plurality of surface control units similar to control unit 132 may be used to send production system data from the respective wellsites of different reservoirs in the production system to processing system 140. In addition to the above-described SCADA functionality,

processing system 140 may be used to process the received data and simulate fluid production in the multi-reservoir system, as will be described in further detail below.

FIG. 2 is a block diagram of an exemplary system 200 for simulating fluid production in a multi-reservoir system. For example, system 200 may be used to implement a processing system, e.g., processing system 140 of FIGS. 1A and 1B, as described above, for processing wellsite data sent by a surface control unit (e.g., control unit 132 of FIGS. 1A and 1B) of a production well associated with each reservoir in the production system. As shown in FIG. 2, system 200 includes a reservoir simulator 210, a memory 220, a user interface (UI) 230 and a network interface 240. Reservoir simulator 210 includes a fluid model generator 212, a flow simulator 214 and a data presentation unit 216. In an embodiment, reservoir simulator 210 and its components (including fluid model generator 212, flow simulator 214 and presentation unit 216), memory 220, UI 230 and network interface 240 may be communicatively coupled to one another via an internal bus of system 200.

In an embodiment, system 200 can be implemented using any type of computing device having at least one processor and a processor-readable storage medium for storing data and instructions executable by the processor. Examples of such a computing device include, but are not limited to, a desktop computer, a workstation, a server, a cluster of computers (e.g., in a server farm) or similar type of computing device. Such a computing device may also include an input/output (I/O) interface for receiving user input or commands via a user input device (not shown). The user input device may be, for example and without limitation, a mouse, a QWERTY or T9 keyboard, a touch-screen, a graphics tablet, or a microphone. The I/O interface may also include a display interface for outputting or presenting information on a display (not shown) coupled to or integrated with the computing device.

While only reservoir simulator 210, memory 220, UI 230 and network interface 240 are shown in FIG. 2, it should be appreciated that system 200 may include additional components, modules, and/or sub-components as desired for a particular implementation. It should also be appreciated that reservoir simulator 210 and its components may be implemented in software, firmware, hardware, or any combination thereof. Furthermore, it should be appreciated that embodiments of reservoir simulator 210, or portions thereof, can be implemented to run on any type of processing device including, but not limited to, a

computer, workstation, embedded system, networked device, mobile device, or other type of processor or computer system capable of carrying out the functionality described herein.

In an embodiment, system 200 may use network interface 240 to communicate with different devices and other systems via a network 204. Network 204 can be any type of network or combination of networks used to communicate information between different computing devices. Network 204 can include, but is not limited to, a wired (e.g., Ethernet) or a wireless (e.g., Wi-Fi or mobile telecommunications) network. In addition, network 204 can include, but is not limited to, a local area network, medium area network, and/or wide area network such as the Internet.

In an embodiment, system 200 may use network interface 240 to send and receive information to and from a wellsite control and monitoring device, e.g., surface control unit 132 of FIGS. 1A and 1B, as described above, via network 204. Such information may include, for example, production system data sent from the wellsite control and monitoring device to system 200 via network 204. Likewise, various control signals and commands may be sent by system 200 to the wellsite control and monitoring device via network 204, e.g., for purposes of controlling wellsite operations or requesting wellsite production system data from the device. In some implementations, such control signals may be in the form of telemetry signals sent using a telemetry transceiver integrated within network information 240 of system 200.

In an embodiment, the control signals or commands sent by system 200 to the device at the wellsite may be based on input received from a user 202 via UI 230. User 202 may interact with UI 230 via a user input device (e.g., a mouse, keyboard, or touch-screen) and a display coupled to system 200 to configure, control or monitor the execution of production system simulation. In accordance with user input received by reservoir simulator 210 via UI 230, production system data may be requested and received from a wellsite control and monitoring device via network 204, as described above. The data received from the device may be processed and used by reservoir simulator 210 in the production system simulation. The results of the simulation may then be presented by presentation unit 216 to user 202 via UI 230.

In an embodiment, memory 220 may be used to store the production system data from the device in the above example in addition to various other types of data accessible by reservoir simulator 210 and its components (including fluid model generator 212, flow

simulator 214 and presentation unit 216) for implementing the production system simulation functionality disclosed herein. Memory 220 can be any type of recording medium coupled to an integrated circuit that controls access to the recording medium. The recording medium can be, for example and without limitation, a semiconductor memory, a hard disk, or similar type of memory or storage device. In some implementations, memory 220 may be a remote cloud-based storage location accessible to system 200 via network interface 240 and network 204.

In the example shown in FIG. 2, the data stored in memory 220 may include production data 222, fluid data 224 and simulation data 226. As will be described in further detail below, reservoir simulator 210 may use a combination of production data 222, fluid data 224 and simulation data 226 to derive a desired set of operating points for a given time-step of the production system simulation.

Production data 222 may include, for example, actual and/or simulated production system measurements. Actual production system measurements may include, for example, surface and downhole well measurements from various production wells in the multi-reservoir system. Such measurements may include, but are not limited to, pressure, temperature and fluid flow measurements taken downhole near the well perforations, along the production string, at the wellhead and within the gathering network prior to the point where the fluids mix with fluids from other reservoirs. Likewise, the simulated measurements may include, for example and without limitation, estimates of pressure, temperature and fluid flow. Such estimates may be determined based on, for example, simulation results from one or more previous time-steps.

Fluid data 224 may represent different reservoir fluid components (e.g., heavy crude, light crude, methane, etc.) and related properties including, for example, their proportions, fluid density and viscosity for various compositions, pressures and temperatures, or other data. In an embodiment, fluid data 224 may include black oil data, e.g., in the form of one or more black oil tables, representing the fluids of each reservoir within the multi-reservoir production system.

In an embodiment, fluid model generator 212 may generate a fluid model for each reservoir in the multi-reservoir system based on corresponding production data 222 and fluid data 224. For example, fluid model generator 212 may determine parameters for each fluid component or group of components of the reservoir based on actual and simulated

production system measurements (e.g., from one or more prior simulation time-steps) and fluid component characterizations associated with each reservoir. The resulting model for each component/group can then be applied to known state variables to calculate unknown state variables at each simulation point or “gridblock” within the reservoir, at the wellbore perforations or “sandface,” and within the common gathering network of the production system. These unknown variables may include, for example and without limitation, each gridblock’s liquid volume fraction, solution gas-oil ratio and formation volume factor.

In an embodiment, the resulting fluid component state variables, both measured and calculated, may be provided as inputs to flow simulator 214 for simulating the flow of fluids through the multi-reservoir production system. Additional inputs to flow simulator 214 may include, for example, various floating parameters, fixed parameters and characterization data related to the production system and constraints thereof. The floating parameters may include, for example, various enhanced oil recovery (EOR) parameters including, but not limited to, gas lift injection rates, reservoir gas injection rates and reservoir liquid injection rates. Examples of fixed parameters may include facility constraints (e.g., a production capacity limit) and default production rates for individual wells. Reservoir characterization data may include, for example, geological data describing reservoir formations (e.g., log data previously collected during drilling and/or prior logging of the well) and formation characteristics (e.g., porosity). The above-described fluid component state variables along with the other simulation inputs, parameters and production system constraints may be stored in memory 220 as simulation data 226.

In an embodiment, flow simulator 214 may employ set of a fully-coupled equations to perform the simulation and determine optimal operating settings for the production system such that production of the reservoirs can be maximized over time without exceeding any facility constraints. The equations are characterized as “fully-coupled” because all the equations for all the reservoirs and the gathering network may be solved simultaneously, rather than solving the reservoir and gathering network separately and iterating between the reservoir and gathering network solutions to determine appropriate boundary conditions for each set of equations (i.e., loosely-coupled).

In an embodiment, the fully-coupled equations may be used with any of various numerical analysis techniques (e.g., a Newton-Raphson method) to determine a set of mass and/or volume balance values for each gridblock. The equations also may be used to

determine the flow of fluids through the production system and provide a solution that includes operating settings that honor the various production system constraints, e.g., one or more facility constraints, gathering network constraints, well constraints, or reservoir constraints. Further, the equations may be used by flow simulator 214 to determine
 5 updated fluid properties (e.g., updated fluid component mass and volume values for each gridblock) at the end of the simulation time-step. At least some of the updated parameters may be provided, for example, as previous time-step data for subsequent simulation time-steps. In addition, the simulation performed by flow simulator 214 may be repeated for each of a plurality of different time-steps, where the simulation results for a given time-step
 10 are used to update the simulation for the next time-step.

With the state of the fluids known throughout the production system, the flow of fluid can be simulated using mass/volume balance equations representative of the reservoir, of perforations in the wellbore and of the gathering network. In an embodiment, the facility equations representing the gathering network include molar balance equations at the
 15 nodes, hydraulic equations, constraint equations, and composition equations. The independent variables for the facility equations include pressure and composition for the nodes, and molar flow rates for the connections.

The full system of equations can be expressed as follows:

$$\begin{bmatrix} A_{rr} & A_{rf} \\ A_{rp} & A_{pf} \\ A_{fp} & A_{ff} \end{bmatrix} \begin{bmatrix} \delta x_r \\ \delta x_p \\ \delta x_f \end{bmatrix} = - \begin{bmatrix} R_r \\ R_p \\ R_f \end{bmatrix} \quad (1)$$

where $\mathbf{R}$ denotes the residuals, and $\mathbf{A}$ the Jacobian for a Newton iteration of the production system simulation. $\mathbf{A}$ contains the derivatives of the residuals with respect to the variables x , where x_r includes gridblock moles and pressures, x_p includes perforation flow rates, and x_f includes facility node compositions and pressures and the total molar flow rate of the facility connections. The first row of equations represents the reservoir equations
 25 (simulating fluid flow through the reservoir), the second row represents the perforation equations (simulating fluid flow through the perforations), and the third row represents the facility equations (simulating fluid flow through the gathering network).

In an embodiment, the reservoir equations include molar balance equations of the form:

$$R_{ri} = F_i^{in} - F_i^{out} - a_i + G_i - \sum_{p \in p_r} Q_{rpi} \quad (2)$$

where the residual R_{ri} of component i for each reservoir gridblock r is driven to zero at full convergence of the equations. For component i , F_i^{in} and F_i^{out} are the molar flow rates across reservoir gridblock faces, a_i is the rate of accumulation, G_i is the rate of generation and Q_{rpi} is the perforation flow rate (positive for production, negative for injection) between a reservoir gridblock r and a wellbore through perforation p . The Q_{rpi} are summed over the perforations within gridblock r . The independent variables are the mass (in moles) of each component i , and the gridblock pressure. In addition to the molar balance equations, in at least some illustrative embodiments a volume balance equation operates to constrain the pore volume so that it equals the fluid volume. This can be written in residual form as:

$$R_{r,nc_r+1} = V_{Pr} - V_{Fr} \quad (3)$$

where nc_r is the number of reservoir pseudo-components, V_{Pr} is the pore volume and V_{Fr} is the fluid volume for gridblock r .

In at least some illustrative embodiments, the perforation equations are expressed as flow equations for each perforation within a reservoir gridblock. Starting with the simpler case of a single reservoir and a gathering network with the same number of pseudo-components, the perforation equation for producing perforations can be expressed using the flow equation,

$$Q_{rpi} = C_p \Delta\Phi_p \sum_{m=1}^{Nphases} \frac{krel_{rm}}{\mu_{rm}} \rho_{rm} z_{rmi} \quad (4)$$

where Q_{rpi} is the perforation flow rate of fluid pseudo-component i for perforation p within gridblock r , C_p is the wellbore constant (equal to the well index multiplied by the permeability-thickness product), $\Delta\Phi_p$ is the permeability-thickness product (i.e., the potential difference from the reservoir to the wellbore for perforation p), and where for phase m within gridblock r , $krel_{rm}$ is the relative permeability, μ_{rm} is the viscosity, ρ_{rm} is the density, and z_{rmi} is the mole fraction of fluid pseudo-component i . Similarly, the perforation equation for injecting perforations can be expressed using the flow equation,

$$Q_{rpi} = C_p \lambda_p^{inj} \rho_p^{inj} \Delta\Phi_p z_{rpi} \quad (5)$$

where λ_p^{inj} is the fluid mobility (e.g., the sum of the gridblock phase mobilities or an endpoint mobility), ρ_p^{inj} is the perforation-injected fluid density, and z_{rpi} is the component mole fraction at a node in the wellbore.

The above-described simulation assumes a configuration of the production system in which multiple reservoirs are coupled to a common surface or gathering network. Such a gathering network may include, for example, a plurality of nodes with connections between the nodes and various reservoir gridblocks. Nodes may represent physical locations of relevant components or devices (e.g., separator 310 of FIG. 3, as will be described below) within the gathering network and/or the production wells of various reservoirs. Connections may represent pipes or flow control devices, for example, pumps, compressors, valves, or similar types of devices. An example of such a production system configuration is shown in FIG. 3.

FIG. 3 is a diagram illustrating an exemplary multi-reservoir system including a common surface or gathering network. As shown in FIG. 3, a group of N reservoirs 302-1 through 302-N are coupled together through a gathering network 320. Individual well lines 304 (1 through N) from each well couple to a corresponding reservoir node 306 (1 through N), with each node coupling through a reservoir line 305 (1 through N) to a common node 308. Common node 308 may provide, for example, mixed fluids produced from reservoirs 302-1 to 302-N through riser 309 to a processing facility 300. The mixed fluids that are produced at common node 308 through riser 309 may include fluids produced from any number of reservoirs 302-1 to 302-N, for example, all of the reservoirs or any subset thereof. In the example shown, processing facility 300 includes a separator 310 that receives the mixed product from facility riser 309 and separates the product into water, oil and gas. These separated products are respectively stored in water storage 312, oil storage 316 and gas storage 314 for later use and/or delivery further downstream (e.g., to a refining facility). Alternatively, some of the separated product may be used to assist with the removal of product from the reservoir. For example, a portion of the separated gas and/or water may be reinjected into one or more reservoirs as part of an enhanced oil recovery (EOR) operation, as indicated by the dashed arrows in FIG. 3.

Maximizing fluid production in the multi-reservoir production system of FIG. 3 may involve controlling the production of each individual well such that the combined

production of the wells, or a selected group of the wells, provides the greatest possible amount of hydrocarbon (e.g., oil and/or gas) production within the operating limits of processing facility 300 and without exceeding any production system constraints. In an embodiment, optimal well operating points that maximize fluid production over time and enable processing facility 300 to operate within its limits may be determined from the results of a simulation of fluid production in the multi-reservoir system. For example, reservoir simulator 210 of FIG. 2, as described above, may be used to identify the optimal well operating points from a simulation of fluid production in the multi-reservoir system of FIG. 3 based on production system measurements, reservoir characterizations and constraints related to reservoirs 302-1 to 302-N and processing facility 300. In some implementations, such operating points may be expressed as a solution to a simultaneous set of fully-coupled equations, as described above.

In addition to using simulation results to determine optimal well operating points and maximize fluid production in the multi-reservoir system, a reservoir engineer (e.g., user 202 of reservoir simulator 210 of FIG. 2) might be interested in improving the computational efficiency of the simulation itself and the accuracy of the simulation results. As will be described in further detail below, the fluid modeling and production simulation techniques disclosed herein may allow such improvements to be achieved for the simulation by using a modified black oil model representing the mixed fluids produced from the multiple reservoirs of the above-described multi-reservoir production system.

Referring to FIG. 3, each of reservoirs 302-1 to 302-N may be associated with a black oil model, e.g., in the form of one or more black oil tables, representing the fluids within that reservoir. In this example, each reservoir may have at least two fluid components, e.g., an oil component and a gas component, which can be produced into gathering network 320. In an embodiment, it may be assumed for purposes of the simulation that the gas components of reservoirs 302-1 to 302-N are identical while the oil components maintain their separate identities for each reservoir. However, it should be noted that the gas components also may retain their separate identities in some implementations, e.g., for more flexibility when dealing with condensate reservoirs.

In an embodiment, a modified black oil model, e.g., in the form of a multi-dimensional or expanded black oil table, may be used to represent mixed fluids produced at different points in the common surface network from different reservoirs coupled to the

network. In an embodiment, the multi-dimensional or expanded black oil table may be generated in terms of pressure and the mass fractions of each of the oil components (of which there may be more than one per reservoir). Such a multi-dimensional table may include, for example, at least as many oil components as the number of reservoirs in the multi-reservoir production system.

As will be described in further detail below with respect to the process shown in FIG. 4, the multi-dimensional table for the modified black oil model may be generated based on matching one or more black oil tables representing the fluids in each reservoir with an EOS model. While the EOS models for the reservoirs in the multi-reservoir system may have at least some light components in common, the disclosed embodiments do not require the EOS model for each reservoir to have the same EOS components as in conventional approaches, which generally convert black oil properties for each reservoir to a common EOS model. For example, in accordance with the disclosed embodiments, there may be at least one unique heavy component for each reservoir in the multi-reservoir system.

Conventional approaches also tend to delump black oil fluids at the sandface to a master EOS component set for use in the gathering network. The delumping may involve, for example, extracting a detailed compositional breakdown of fluids produced in the network based on previously lumped fluid components. In contrast with such conventional approaches, the disclosed embodiments use a modified black oil model, as described above, which may be generated by combining different proportions of the production streams from individual reservoirs in their EOS component forms. Thus, the disclosed embodiments avoid delumping the fluids in their black oil form to a common compositional form. Instead, the disclosed embodiments use the original black oil model or table(s) associated with each reservoir to calculate fluid properties during the simulation for points in the network where there is no commingling or mixing of fluids from different reservoirs. For other points in the network where mixing occurs, a multi-dimensional or expanded black oil table may be generated and used to calculate the properties of the mixed fluids from different reservoirs, as described above.

Without having to generate a detailed compositional breakdown of the produced fluids as with conventional approaches that use a delumping process, the expanded or multi-dimensional black oil tables described herein may be used to calculate properties of

the fluids produced at different points in the common surface/gathering network with significant improvements in computational efficiency and simulation results that are at least as accurate, if not more accurate, than the results obtained using such conventional approaches.

5 FIG. 4A is a flowchart of an exemplary method 400A of generating a modified black oil model for determining the properties of mixed fluids produced in a multi-reservoir system having a common surface network. For discussion purposes, method 400 will be described using the above-described multi-reservoir system of FIG. 3 but is not intended to be limited thereto. As shown in FIG. 4A, method 400A includes steps 402 and
10 404. However, it should be noted that method 400 may include additional steps to perform the techniques disclosed herein, as desired for a particular implementation. The steps of method 400 may be performed by, for example, reservoir simulator 210 of FIG. 2, as described above, but method 400 is not intended to be limited thereto.

Method 400A begins in step 402, which includes matching black oil data with a
15 common EOS model for each of a plurality of reservoirs (e.g., reservoirs 302-1 to 302-N of FIG. 3) in the multi-reservoir system. The black oil data for each reservoir in this example may represent the fluids within that reservoir. In an embodiment, the black oil data may be stored in the form of one or more black oil tables associated with each reservoir in the multi-reservoir system. In an embodiment, a single EOS model may be generated for the
20 common network. However, some of the components may not exist in all of the reservoirs, and the fluids from different reservoirs will have different compositions. A pseudoized light fluid component may be created, which represents the common gas from all the reservoirs. In some cases, unique light fluid components may be required for each reservoir fluid. At least one pseudoized heavy oil component may be generated for each
25 reservoir. The mass fraction of the heavy components are used, for example, as interpolation parameters in the generated modified black oil table. In an embodiment, the common light fluid components may be gas components and the unique heavy oil component may be an oil component.

Method 400A then proceeds to step 404, which includes generating at least one
30 multi-dimensional or expanded black oil table representing the mixed fluids produced from the different reservoirs. The multi-dimensional black oil table may be generated, for example, as a function of the temperature, pressure and the mass fractions of the respective

oil components produced from each of the reservoirs. In an embodiment, the EOS model from step 402 is used to generate saturated and under-saturated black oil fluid property tables at different temperatures and for mixtures comprised of different proportions of the reservoir fluids. Additionally, a unique oil pseudo-component may be used to interpolate
5 between tables at the same temperature. As shown in FIG. 4A, method 400A may then proceed to, for example, method 400B, as shown in FIG. 4B. However, it should be noted that method 400A is not intended to be limited thereto.

FIG. 4B is a flowchart of an exemplary method 400B of using the modified black oil model generated in method 400A of FIG. 4A, as described above. The modified black
10 oil model in this example may be used to determine the properties of mixed fluids produced in a multi-reservoir system having a common surface network, e.g., as described above with respect to FIG. 3. However, method 400B is not intended to be limited thereto. As shown in FIG. 4B, method 400B includes steps 406, 408, 410, 412 and 414. However, it should be noted that method 400B may include additional steps to perform the techniques
15 disclosed herein, as desired for a particular implementation. The steps of method 400B may be performed by, for example, reservoir simulator 210 of FIG. 2, as described above.

Method 400B begins in step 406, which includes simulating fluid production in the multi-reservoir system at different points in the common surface network. The simulation points may correspond to, for example, different nodes (e.g., nodes 306-1 to 306-N of FIG.
20 3) in the common surface network, as described above. In step 408, it is determined for each simulation point whether there are mixed fluids produced from different reservoirs. In step 410, the results of the determination from step 408 may be used to decide whether method 400B will proceed to step 412 or step 414. In an example, if it is determined in step 408 that the fluids at a particular simulation point in the network are produced from
25 only a single reservoir, method 400B may proceed from step 410 to step 412. Step 412 may include calculating fluid properties using the original black oil table(s) (e.g., also used in step 402 of method 400A of FIG. 4A, described above) of the corresponding reservoir from which the fluids are produced. For example, in cases where fluid production occurs from only a single reservoir, the fluid properties may only be a function of pressure and the
30 original black oil data associated with the reservoir from which the fluids are produced may be used to calculate fluid properties.

Alternatively, if it is determined in step 408 that there is a commingling or mixing of fluids from different reservoirs at the particular simulation point in the above example, method 400B may proceed from step 410 to step 414. In step 414, the multi-dimensional black oil table(s), e.g., as generated in step 404 of method 400A of FIG. 4A, as described
 5 above, may be used to calculate the properties of the mixed fluids from the different reservoirs in this example.

Referring back to FIG. 4A, examples of the input black oil tables (in step 402 of method 400A) and the resulting multi-dimensional black oil tables of the modified black oil model (in step 404 of method 400A) will now be described in the context of simulating
 10 fluid production from two reservoirs through a common surface network, as described above. It should be noted that the data in the following tables are provided for illustrative purposes only and do not represent any particular reservoir fluid.

Table 1 below includes the black oil data for reservoir 1 in this example:

Table 1: Original Black Oil Model Data for Reservoir 1

Pressure (psia)	Rs (MSCF/STB)	Bo (STB/RB)
3000	1.2	1.3
2000	0.8	1.2
1000	0.4	1.1
14.7	0.00001	1

The black oil data in Table 1 may provide, for example, a black oil model description of the fluids in reservoir 1, which can be input to a reservoir simulator, e.g., reservoir simulator 210 of FIG. 2, as described above, for performing the simulation. As
 20 shown in Table 1 above, the main data columns of this input table may be for the pressure (in psia), the solution gas oil ratio (Rs) in units of MSCF/STB, and the oil formation volume factor (Bo) in units of STB/RB. While only these three main columns are shown below, it should be noted that embodiments are not intended to be limited thereto and that the table may have additional columns representing other black oil data parameters
 25 including, for example and without limitation, gas FVF, solution gas-oil ratio, oil viscosity, and gas viscosity. Additionally, undersaturated data may be associated with at least one of the pressures.

Table 2 below shows the modified black oil model data for reservoir 1. As shown in Table 2 below, reservoir 1 may include two types of fluid components: (a) component o1, the oil component of reservoir 1, and (2) component g, the common gas component of reservoirs 1 and 2, where the Rs value is converted into the ratio of the mass fractions of component 1 and component g:

Table 2: Modified Black Oil Model Data for Reservoir 1

Pressure (psia)	Mass o1/Mass g	Bo (STB/RB)
3000	0.6667	1.3
2000	1.0	1.2
1000	2.0	1.1
14.7	10000.	1

Table 3 shows the original black oil model data for reservoir 2, which is similar to Table 1 of the black oil data for reservoir 1:

Table 3: Original Black Oil Model Data for Reservoir 2

Pressure (psia)	Rs (MSCF/STB)	Bo (STB/RB)
3000	0.9	1.15
2000	0.6	1.1
1000	0.3	1.05
14.7	0.00001	1

Table 4 shows the modified black oil model data for reservoir 2. According to Table 4, two types of components exist in reservoir 2: (a) component o2, the oil component of reservoir 2, and (2) component g, the common gas component that exists in all reservoirs. As before, the Rs value is converted into the ratio of the mass fractions of component o2 and component g.

Table 4: Modified Black Oil Model Data for Reservoir 2

Pressure (psia)	Mass o2/Mass g	Bo (STB/RB)
3000	0.5333	1.15
2000	0.8	1.1
1000	1.6	1.05
14.7	8000.	1

In an embodiment, an EOS characterization of the reservoir fluid components may be generated using the modified black oil model data in Tables 2 and 4 for reservoirs 1 and 2 when fluids produced from these two reservoirs are commingled or mixed. Such an EOS characterization may be generated using any of various techniques.

In one example, a set of reservoir pseudo-components may be defined using common pseudo-components that overlap between reservoirs 1 and 2. Each of the “pseudo-components” may represent, for example, any number of real fluid components that are grouped together or “lumped” into a single component that can be processed as an individual unit. The use of overlapping common pseudo-components may enable the application of fully-coupled mass/volume balance equations to multiple reservoirs, wells and the gathering network using a larger but still relatively small number of common pseudo-components (e.g., less than the total of all the reservoir pseudo-components). The common pseudo-components represent a common fluid characterization that includes sufficient components to represent the behavior of multiple fluids in different reservoirs.

The common characterization in this example may be based on an expression of the components as common pseudo-components that are defined based on the components’ bulk hydrocarbon composition or carbon number up to C45. N₂, CO₂, C₁, C₂, C₃, nC₄, iC₄, nC₅, iC₅ and C₆ are used with their commonly accepted properties, while the C₇+ heavy components are defined using a probability distribution function that provides the molecular weight and mole fraction for each carbon number from C₇ to C₄₅. It should be appreciated that any of various techniques may be used to define the C₇+ heavy components. Once a set of molecular weights and mole fractions are established, a Watson or other type of characterization factor may be calculated for each common pseudo-component, which in turn may be used to calculate the specific gravity of each common pseudo-component. It should be appreciated that any of various techniques may be used to calculate pseudo-component specific gravities and/or other pseudo-component characteristics will become apparent to those of ordinary skill in the art, and all such techniques are within the scope of the present disclosure. The true boiling point (TBP) for each common pseudo-component may also be calculated. The molecular weights, TBPs and specific gravities can be combined using any of a number of correlation techniques to

calculate the critical properties needed by the fluid models. Non-zero interaction coefficients may also need to be estimated through correlations.

At this stage, a large number of pseudo-components may be used, far larger than the usual number normally used to simulate reservoir and network systems. In typical approaches previously published, the next step would be to combine the pseudo-components into a smaller set of components (a process called pseudoization) in order to reduce the costs of the calculations. In our approach, the pseudoization approach is unnecessary because the fluid representation is only used to generate the black oil tables so the number of components is immaterial.

The critical properties and the interaction coefficients generated in the above manner may need to be adjusted to adequately match the fluid properties represented by the original black oil tables. Regression methods may be applied to adjust the values of the fluid parameters.

After the common EOS model has been generated by fitting the data of all the black oil models, we are left with an EOS that has most of the components shared by all fluids and perhaps some components which are unique to a particular fluid. The distinguishing characteristic of fluids from different reservoirs is that the composition of each fluid is different.

We introduce the idea of a unique oil pseudo-component for each of the reservoirs fluids. Some reservoirs have multiple black oil models input, and may require multiple oil pseudo-components. During the mixture calculations used to calculate the modified black oil table, different proportions of each reservoir oil are mixed together. The oil compositions are expanded to their EOS component representation so that the fluid properties of the mixture can be calculated.

To generate black oil properties at a particular temperature using the EOS model, the composition of the mixed fluid is first set by mixing the different black oil fluids at different pressures and different proportions.

For example, with two reservoirs, an additional interpolation parameter is introduced, the mass fraction of the oil component in reservoir 2 (mass of component o2/(mass of component o1 + mass of component o2)). This interpolation parameter is referenced herein as x2. A table is created for each tabulated value of x2. When x2 is equal to 0, the data is equivalent to the modified black oil model data for reservoir 1.

When x_2 is equal to 1, the data is equivalent to the modified black oil model data for reservoir 2. Other data will be entered for values of x_2 between 0 and 1. The intermediate data is calculated by the characterized equation of state and the results will be non-linear.

Tables 5-7 below show examples of the modified black oil model data for different values of x_2 :

Table 5: Modified Black Oil Model Data for $x_2 = 0.0$

Pressure (psia)	Mass o1/Mass g	Mass o2/Mass g	Bo (STB/RB)
3000	0.6667	0	1.3
2000	1.0	0	1.2
1000	2.0	0	1.1
14.7	10000.	0	1

Table 6: Modified Black Oil Model Data for $x_2 = 0.5$

Pressure (psia)	Mass o1/Mass g	Mass o2/Mass g	Bo (STB/RB)
3000	0.333	0.2517	1.22
2000	0.5	0.4	1.15
1000	1	0.8	1.08
14.7	5000	4000	1

Table 7: Modified Black Oil Model Data for $x_2 = 1.0$

Pressure (psia)	Mass o1/Mass g	Mass o2/Mass g	Bo (STB/RB)
3000	0	0.5333	1.15
2000	0	0.8	1.1
1000	0	1.6	1.05
14.7	0	8000	1

At any pressure, the mass ratios of all the components are combined to yield a ratio of total oil mass over total gas mass. This provides the equilibrium state of the mixture.

These tables are used to look up the properties of the saturated black oil. Another table or coefficients of equations are used to calculate the properties of the undersaturated properties.

For example, the undersaturated oil formation oil factor (B_o) is commonly calculated in equation form by:

$$B_o = B_{o,b} \exp(c_o(p - p_b)) \quad (6)$$

where $B_{o,b}$ is the formation volume factor at the bubblepoint pressure, p_b , and c_o is the oil compressibility. The oil compressibility can be entered for each oil type, and we can

calculate a modified value for a mixed fluid. For example, if we have n fluids, we could calculate a mixture value for c_o by weighting the values of the individual compressibilities.

A possible formula would be as follows:

$$c_{o,mix} = \sum_{i=1}^n w_i c_{o,i} \quad (7)$$

5 where the weightings w_i would be a function of the mass fractions x_i .

It should be noted that in a surface network, a set of tables must be also be generated for a range of temperatures, so temperature becomes another interpolation parameter.

The produced fluids from each reservoir may have a special or unique oil component and a special/unique or common gas component. For each additional reservoir added, another level of interpolation may be added. Further, if the gas components in each reservoir maintain their uniqueness, another interpolation parameter related to the fraction of the gas component from one of the reservoirs will be added to the tables.

Accordingly, the disclosed embodiments provide systems and method for matching black oil models tied to a common network to EOS models without the requirement that all components must exist within each fluid. Also, in contrast to other approaches that delump the black oil fluids to the common EOS model at the sandface, the disclosed embodiments generate a multi-dimensional black oil table with the oil component (and possibly gas component) from each reservoir as a parameter.

Advantages of the disclosed embodiments over conventional approaches include increasing computational efficiency and accuracy in most cases, may be more. Additionally, in parts of the reservoir that have no commingling of fluids from different reservoirs, the original black oil table data may be used. Accordingly, the disclosed embodiments allow reservoir operators to keep their original black oil fluid characterizations, while creating a reasonable basis for generating properties for mixed black oil fluids. The disclosed embodiments may be implemented within, for example, an integrated reservoir and surface network simulator. The disclosed fluid modeling and simulation may be used, for example, as a basis for calculating the fluid properties of fluids that are created from the mixing of black oil fluids from different reservoirs in different proportions, and also for generating fluid properties at temperatures other than those for which the original model was generated.

FIG. 5 is a block diagram of an exemplary computer system 500 in which embodiments of the present disclosure may be implemented. The system 500 may be any type of computing device including, but not limited to, a desktop computer, a laptop, a server, a tablet, and a mobile device. The system 500 includes, among other components, a processor 510, main memory 502, secondary storage unit 504, an input/output interface module 506, and a communication interface module 508.

The processor 510 may be any type or any number of single core or multi-core processors capable of executing instructions for performing the features and functions of the disclosed embodiments. The input/output interface module 506 enables the system 500 to receive user input (e.g., from a keyboard and mouse) and output information to one or more devices such as, but not limited to, printers, external data storage devices, and audio speakers. The system 500 may optionally include a separate display module 511 to enable information to be displayed on an integrated or external display device. For instance, the display module 511 may include instructions or hardware (e.g., a graphics card or chip) for providing enhanced graphics, touchscreen, and/or multi-touch functionalities associated with one or more display devices.

Main memory 502 is volatile memory that stores currently executing instructions/data or instructions/data that are prefetched for execution. The secondary storage unit 504 is non-volatile memory for storing persistent data. The secondary storage unit 504 may be or include any type of data storage component such as a hard drive, a flash drive, or a memory card. In one embodiment, the secondary storage unit 504 stores the computer executable code/instructions and other relevant data for enabling a user to perform the features and functions of the disclosed embodiments.

For example, in accordance with the disclosed embodiments, the secondary storage unit 504 may permanently store executable code/instructions 520 for performing the above-described procedure for using a modified black oil model for calculating mixing of different fluids in a common surface network. The executable code/instructions 520 are then loaded from the secondary storage unit 504 to main memory 502 during execution by the processor 510 for performing the disclosed embodiments. In addition, the secondary storage unit 504 may store other executable code/instructions and data 522 such as, but not limited to, a reservoir simulation application (e.g., Nexus® reservoir simulation software) for use with the disclosed embodiments.

The communication interface module 508 enables the system 500 to communicate with the communications network 530. For example, the network interface module 508 may include a network interface card and/or a wireless transceiver for enabling the system 500 to send and receive data through the communications network 530 and/or directly with other devices.

The communications network 530 may be any type of network including a combination of one or more of the following networks: a wide area network, a local area network, one or more private networks, the Internet, a telephone network such as the public switched telephone network (PSTN), one or more cellular networks, and/or wireless data networks. The communications network 530 may include a plurality of network nodes (not depicted) such as routers, network access points/gateways, switches, DNS servers, proxy servers, and other network nodes for assisting in routing of data/communications between devices.

For example, in one embodiment, the system 500 may interact with one or more servers 534 or databases 532 for performing the features of the disclosed embodiments. For instance, the system 500 may query the database 532 for well log information for creating a reservoir model in accordance with the disclosed embodiments. Further, in certain embodiments, the system 500 may act as a server system for one or more client devices or a peer system for peer to peer communications or parallel processing with one or more devices/computing systems (e.g., clusters, grids).

As described above, embodiments of the present disclosure, including the modified black oil modeling techniques disclosed herein, are particularly useful for calculating properties of mixed fluids produced in a multi-reservoir system with a common surface network. In one embodiment of the present disclosure, a computer-implemented method of simulating fluid production in a multi-reservoir system with a common surface network includes: matching black oil data with a common equation of state (EOS) model for each of a plurality of reservoirs, the black oil data representing fluids within each reservoir; generating at least one multi-dimensional black oil table representing a mix of the fluid components to be produced from each of the plurality of reservoirs via the common surface network, based on the EOS model that matches the one or more black oil tables for each reservoir; and calculating properties of the fluids in the mix during a simulation of fluid

production from the plurality of reservoirs, based on the generated multi-dimensional black oil table for each reservoir.

In a further embodiment, the different fluid components represented by the EOS model for each reservoir are lumped into at least one heavy fluid component that is unique to that reservoir, and the one or more black oil tables are matched with the EOS model for each reservoir based on the reservoir's unique heavy fluid component. In a further embodiment, the different fluid components further include at least one light fluid component that is common amongst the plurality of reservoirs. In a further embodiment, the heavy fluid component is a unique heavy oil component and the light fluid component is a common gas component. In a further embodiment, the multi-dimensional black oil table represents the fluids of each of the plurality of reservoirs in proportion to the unique heavy oil component of each reservoir relative to the reservoir's fluid pressure. In a further embodiment, the generating of the at least one multi-dimensional black oil table includes determining a mass fraction of the unique heavy oil component of each reservoir, based on the corresponding EOS model and generating at least one multi-dimensional black oil table based on the mass fraction determined for each reservoir and the reservoir's fluid pressure. In a further embodiment, the multi-dimensional black oil tables are generated as a function of pressure, temperature and a proportion of the unique heavy oil component of the EOS model for each reservoir. In a further embodiment, the light fluid component is a unique gas component and the multi-dimensional black oil tables are generated as a function of pressure, temperature and a proportion of the unique gas component of the EOS model for each reservoir.

In another embodiment of the present disclosure, a system for defining non-linear petrofacies for a reservoir simulation model includes at least one processor and a memory coupled to the processor has instructions stored therein, which when executed by the processor, cause the processor to perform functions, including functions to: match black oil data with a common equation of state (EOS) model for each of a plurality of reservoirs, the black oil data representing fluids within each reservoir; generate at least one multi-dimensional black oil table representing a mix of the fluid components to be produced from each of the plurality of reservoirs via the common surface network, based on the EOS model that matches the one or more black oil tables for each reservoir; and calculate

properties of the fluids in the mix during a simulation of fluid production from the plurality of reservoirs, based on the generated multi-dimensional black oil table for each reservoir.

In yet another embodiment of the present disclosure, a computer-readable storage medium has instructions stored therein, which when executed by a computer cause the computer to perform a plurality of functions, including functions to: match black oil data with a common equation of state (EOS) model for each of a plurality of reservoirs, the black oil data representing fluids within each reservoir; generate at least one multi-dimensional black oil table representing a mix of the fluid components to be produced from each of the plurality of reservoirs via the common surface network, based on the EOS model that matches the one or more black oil tables for each reservoir; and calculate properties of the fluids in the mix during a simulation of fluid production from the plurality of reservoirs, based on the generated multi-dimensional black oil table for each reservoir.

While specific details about the above embodiments have been described, the above hardware and software descriptions are intended merely as example embodiments and are not intended to limit the structure or implementation of the disclosed embodiments. For instance, although many other internal components of the system 500 are not shown, those of ordinary skill in the art will appreciate that such components and their interconnection are well known.

In addition, certain aspects of the disclosed embodiments, as outlined above, may be embodied in software that is executed using one or more processing units/components. Program aspects of the technology may be thought of as “products” or “articles of manufacture” typically in the form of executable code and/or associated data that is carried on or embodied in a type of machine readable medium. Tangible non-transitory “storage” type media include any or all of the memory or other storage for the computers, processors or the like, or associated modules thereof, such as various semiconductor memories, tape drives, disk drives, optical or magnetic disks, and the like, which may provide storage at any time for the software programming.

Additionally, the flowchart and block diagrams in the figures illustrate the architecture, functionality, and operation of possible implementations of systems, methods and computer program products according to various embodiments of the present invention. It should also be noted that, in some alternative implementations, the functions noted in the block may occur out of the order noted in the figures. For example, two blocks

shown in succession may, in fact, be executed substantially concurrently, or the blocks may sometimes be executed in the reverse order, depending upon the functionality involved. It will also be noted that each block of the block diagrams and/or flowchart illustration, and combinations of blocks in the block diagrams and/or flowchart illustration, can be
5 implemented by special purpose hardware-based systems that perform the specified functions or acts, or combinations of special purpose hardware and computer instructions.

The above specific example embodiments are not intended to limit the scope of the claims. The example embodiments may be modified by including, excluding, or combining one or more features or functions described in the disclosure.

CLAIMS

WHAT IS CLAIMED IS:

1. A computer-implemented method of simulating fluid production in a multi-reservoir system with a common surface network, the method comprising:

matching black oil data with a common equation of state (EOS) model for each of a plurality of reservoirs, the black oil data representing fluids within each reservoir;

generating at least one multi-dimensional black oil table representing a mix of the fluid components to be produced from each of the plurality of reservoirs via the common surface network, based on the EOS model that matches the one or more black oil tables for each reservoir; and

calculating properties of the fluids in the mix during a simulation of fluid production from the plurality of reservoirs, based on the generated multi-dimensional black oil table for each reservoir.

2. The method of claim 1, wherein the different fluid components represented by the EOS model for each reservoir are lumped into at least one heavy fluid component that is unique to that reservoir, and the one or more black oil tables are matched with the EOS model for each reservoir based on the reservoir's unique heavy fluid component.

3. The method of claim 2, wherein the different fluid components further include at least one light fluid component that is common amongst the plurality of reservoirs.

4. The method of claim 3, wherein the heavy fluid component is a unique heavy oil component and the light fluid component is a common gas component.

5. The method of claim 4, wherein the multi-dimensional black oil table represents the fluids of each of the plurality of reservoirs in proportion to the unique heavy oil component of each reservoir relative to the reservoir's fluid pressure.

6. The method of claim 5, wherein generating at least one multi-dimensional black oil table comprises:

determining a mass fraction of the unique heavy oil component of each reservoir, based on the corresponding EOS model; and

5 generating at least one multi-dimensional black oil table based on the mass fraction determined for each reservoir and the reservoir's fluid pressure.

7. The method of claim 5, wherein the multi-dimensional black oil tables are generated as a function of pressure, temperature and a proportion of the unique heavy oil component of the EOS model for each reservoir.

8. The method of claim 7, wherein the light fluid component is a unique gas component and the multi-dimensional black oil tables are generated as a function of pressure, temperature and a proportion of the unique gas component of the EOS model for each reservoir.

9. A system of simulating fluid production in a multi-reservoir system with a common surface network, the system comprising:

at least one processor; and

20 a memory coupled to the processor having instructions stored therein, which when executed by the processor, cause the processor to perform functions including functions to:

match black oil data with a common equation of state (EOS) model for each of a plurality of reservoirs, the black oil data representing fluids within each reservoir;

25 generate at least one multi-dimensional black oil table representing a mix of the fluid components to be produced from each of the plurality of reservoirs via the common surface network, based on the EOS model that matches the one or more black oil tables for each reservoir; and

calculate properties of the fluids in the mix during a simulation of fluid production from the plurality of reservoirs, based on the generated multi-dimensional black oil table for each reservoir.

10. The system of claim 9, wherein the different fluid components represented by the EOS model for each reservoir are lumped into at least one heavy fluid component that is unique to that reservoir, and the one or more black oil tables are matched with the EOS model for each reservoir based on the reservoir's unique heavy fluid component.

5

11. The system of claim 10, wherein the different fluid components further include at least one light fluid component that is common amongst the plurality of reservoirs.

10

12. The system of claim 11, wherein the heavy fluid component is a unique heavy oil component and the light fluid component is a common gas component.

15

13. The system of claim 12, wherein the multi-dimensional black oil table represents the fluids of each of the plurality of reservoirs in proportion to the unique heavy oil component of each reservoir relative to the reservoir's fluid pressure.

14. The system of claim 13, wherein the functions performed by the processor further include functions to:

20

determine a mass fraction of the unique heavy oil component of each reservoir, based on the corresponding EOS model; and

generate at least one multi-dimensional black oil table based on the mass fraction determined for each reservoir and the reservoir's fluid pressure.

25

15. The system of claim 13, wherein the multi-dimensional black oil tables are generated as a function of pressure, temperature and a proportion of the unique heavy oil component of the EOS model for each reservoir.

30

16. The method of claim 16, wherein the light fluid component is a unique gas component and the multi-dimensional black oil tables are generated as a function of pressure, temperature and a proportion of the unique gas component of the EOS model for each reservoir.

17. A computer-readable storage medium having instructions stored therein, which when executed by a computer cause the computer to perform a plurality of functions, including functions to:

match black oil data with a common equation of state (EOS) model for each of a plurality of reservoirs, the black oil data representing fluids within each reservoir;

generate at least one multi-dimensional black oil table representing a mix of the fluid components to be produced from each of the plurality of reservoirs via the common surface network, based on the EOS model that matches the one or more black oil tables for each reservoir; and

calculate properties of the fluids in the mix during a simulation of fluid production from the plurality of reservoirs, based on the generated multi-dimensional black oil table for each reservoir.

18. The computer-readable storage medium of claim 17, wherein the different fluid components represented by the EOS model for each reservoir are lumped into at least one heavy fluid component that is unique to that reservoir, and the one or more black oil tables are matched with the EOS model for each reservoir based on the reservoir's unique heavy fluid component.

19. The computer-readable storage medium of claim 18, wherein the different fluid components further include at least one light fluid component that is common amongst the plurality of reservoirs, the heavy fluid component is a unique heavy oil component and the light fluid component is a common gas component.

20. The system of claim 19, wherein the multi-dimensional black oil table represents the fluids of each of the plurality of reservoirs in proportion to the unique heavy oil component of each reservoir relative to the reservoir's fluid pressure.
