

PAYMENT METHOD, APPARATUS, AND DEVICE

ABSTRACT

Implementations of the present specification disclose a payment method, apparatus, and device. In the case of face-to-face payment, the location information and the payment information are sent to the server through the terminal device of the first user, and the server generates a corresponding payment password and returns the corresponding payment password to the first user. The first user then forwards the payment password (for example, verbally, or forwarding using communication software, etc.) to the second user, and the second user then uploads the location and payment password of the second user to the server. The server performs matching or querying within a certain range based on the location of the second user, to determine whether a same payment password exists. If the matching or query is successful, payment is made.
