

A filter fast Fourier transmultiplexer (216) divides a multi-channel communication signal into single channel communication signals through a cascade of filters (304, 314, 348, 354, 360, 366, 404-418) and mixers (604-610). The output sample rate is maintained at the input sample and memory requirements and multiplications are substantially reduced.
