

PRESS-FITTING DEVICE, PRESS-FITTING JIG, AND MANUFACTURING DEVICE

TECHNICAL FIELD

5 The present disclosure relates to a press-fitting device, a press-fitting jig, and a manufacturing device.

BACKGROUND ART

10 Press-fitting devices for manufacturing a press-fit product by press-fitting a press-fitting component into or with a press-fitting target component are known from Patent document 1 etc. Patent document 1 discloses a press-fitting device that measures a distance between a work and a press-fitting tool with a sensor and keeps a press-fitting distance constant based on an output of the sensor.

[Patent document 1] JP-A-H06-126551

15 Incidentally, the press-fitting device disclosed in Patent document 1 measures a distance between the work and the press-fitting tool with the sensor and a control portion acquires a measurement value of the distance measured by the sensor. The control portion calculates, based on a measurement value, a movement distance value by which to move the press-fitting tool. To move the press-fitting tool, the control portion sends an operation instruction value to a motor based on the movement distance value calculated by itself. The control portion acquires, in real time, a value of a measurement distance between the work and the press-fitting tool measured by the sensor as the press-fitting tool is moved, and compares the measurement distance value with the calculated movement distance value. The control portion performs information processing for sending a stop instruction value to the motor so that the press-fitting tool stops when having moved by a prescribed distance corresponding to the calculated movement distance value that coincides with the measurement distance value.

25 However, the above press-fitting device has a problem that a delay occurs from intended timing to stop the press-fitting tool due to times taken by the detection by the sensor, the calculation by the control portion, the driving of the motor, etc. and, as a result, the press-fitting tool advances to a position past the intended position where to stop it. As such, the above press-fitting device cannot necessarily manufacture a press-fit product with high accuracy.

SUMMARY OF INVENTION

In view of the above circumstances in the art, and an object of the present invention is therefore to provide a press-fitting device, a press-fitting jig, and a manufacturing device that make it possible to manufacture a press-fit product that is higher in accuracy.

5 To attain the above object, one aspect of the invention provides a press-fitting device for press-fitting a press-fitting component with a press-fitting target component, comprising:

a support portion which supports the press-fitting target component; and

10 a pressing mechanism having a press-fitting tool configured to move in a press-fitting direction with respect to the support portion, wherein:

the press-fitting tool comprises:

a pressing portion having a pressing surface which presses the press-fitting component;

15 a restriction portion having a restriction surface configured to come into contact with the press-fitting target component; and

a position setting mechanism which sets a pressing position of the pressing surface of the pressing portion in the press-fitting direction and a restriction position of the restriction surface of the restriction portion in the press-fitting direction according to the press-fitting component and the press-fitting target component.

20 To attain the above object, another aspect of the invention provides a press-fitting jig used in a press-fitting device for press-fitting a press-fitting component with a press-fitting target component, wherein:

the press-fitting device comprises:

25 a support portion which supports the press-fitting target component; and a pressing mechanism having a press-fitting tool configured to move in a press-fitting direction with respect to the support portion;

the press-fitting tool comprises:

30 a pressing portion having a pressing surface which presses the press-fitting component;

a restriction portion having a restriction surface configured to come into contact with the press-fitting target component; and

a position setting mechanism which sets a pressing position of the

pressing surface of the pressing portion in the press-fitting direction and a restriction position of the restriction surface of the restriction portion in the press-fitting direction according to the press-fitting component and the press-fitting target component;

plural restriction portions are arranged in the press-fitting jig at a prescribed interval and the press-fitting jig is provided so as to be configured to move in an arrangement direction of the plural restriction portions; and

the press-fitting jig comprises:

an arrangement portion in which plural restriction portions are arranged at a prescribed interval;

a main body provided with the arrangement portion; and

a main body portion which is supported to the main body movably.

To attain the above object, a further aspect of the invention provides a manufacturing device for manufacturing a press-fit product in which a press-fitting component is fitted with the press-fitting target component, comprising:

a first measuring portion which measures a dimension of the press-fitting target component;

a second measuring portion which measures a dimension of the press-fitting component; and

a press-fitting portion which press-fits the press-fitting component with the press-fitting target component, wherein:

the press-fitting portion comprises a press-fitting device which performs press-fitting based on the dimension of the press-fitting target component and the dimension of the press-fitting component;

the press-fitting device comprises:

a support portion which supports the press-fitting target component; and

a pressing mechanism having a press-fitting tool configured to move in a press-fitting direction with respect to the support portion; and

the press-fitting tool comprises:

a pressing portion having a pressing surface which presses the press-fitting component;

a restriction portion having a restriction surface configured to come into contact with the press-fitting target component; and

a position setting mechanism which sets a pressing position of the pressing surface of the pressing portion in the press-fitting direction and a restriction position of the restriction surface of the restriction portion in the press-fitting direction according to the press-fitting component and the press-fitting target component.

5

The invention provides a press-fitting device, a press-fitting jig, and a manufacturing device that make it possible to manufacture a press-fit product that is higher in accuracy.

DESCRIPTION OF EMBODIMENT

An embodiment of the present invention will be herein described with reference to the drawings. For the sake of convenience, sets of dimensions of individual components shown in the drawings may be different from actual ones of those components.

A press-fitting method that is performed by a press-fitting device and a manufacturing device according to the embodiment is to manufacture a press-fit product C by a press-fitting method of press-fitting one of a press-fitting component A and a press-fitting target component B into or with the other of them by moving the former in a press-fitting direction by a press-fitting tool. The following description will be directed to a case that the press-fitting component A is press-fitted with the press-fitting target component B. More specifically, a rotary assembly C (press-fit product C) of a motor is manufactured by press-fitting an impeller A (press-fitting component A) with a rotor shaft B (press-fitting target component B) of the rotary assembly C.

Fig. 1 shows the rotary assembly C (press-fit product C) to be manufactured by the press-fitting device and the manufacturing device according to the embodiment. As shown in Fig. 1, the rotor shaft B has a shaft portion B1 and a rotary main body B2 which rotates together with the shaft portion B1. The shaft portion B1 is a cylindrical, rod-shaped member having a prescribed length H and diameter. The shaft portion B1 includes, on one side, an attachment target portion B1a to which the impeller A is to be fitted with and is integrated with the rotary main body B2 on the other side. The rotary main body B2 has a prescribed length Hb that is shorter than the length H of the shaft portion B1 and a diameter that is longer than the diameter of the shaft portion B1, and is formed with, as a surface perpendicular to the axial direction, one surface B3a on one side in the axial direction which is parallel with the rotation axis of the

rotary main body B2 and is also formed with, as a surface perpendicular to the axial direction, another surface B3b on the other side in the axial direction.

The impeller A has an impeller main body a having a prescribed length that is shorter
 5 than the length H of the of the shaft portion B1 and a diameter that is longer than the diameter of the shaft portion B1, a top surface A2 that is located on one side, in the axial direction, of the impeller main body a and is perpendicular to the axial direction, a bottom surface A3 that is located on the other side, in the axial direction, of the impeller main body a and is perpendicular to the axial direction, and plural blade portions Aw provided around the impeller main body a.
 10 An insertion hole A1 penetrates through the impeller main body a at its center along the rotation axis Ax so as to have openings in the top surface A2 and the bottom surface A3. The shaft portion B1 of the rotor shaft B is inserted into the insertion hole A1.

In the embodiment, the dimensional accuracy of the separation distance Ha between
 15 the one surface B3a of the rotary main body B2 of the rotor shaft B and the bottom surface A3 of the impeller A is managed. That is, to obtain the preset separation distance dimension Ha, a press-fitting length (also referred to as a “third dimension”) H3 from a top surface B4 (reference surface) of the shaft portion B1 of the rotor shaft B to the top surface A2 of the impeller A is calculated on the basis of the length H1 of a portion, that can be fitted with the
 20 impeller A, of the shaft portion B1 of the rotor shaft B and a thickness H2 dimension of the impeller A in the fitting direction. A rotary assembly C (press-fit product C) having the preset separation distance dimension Ha is manufactured by press-fitting the impeller A with the shaft portion B1 of the rotor shaft B based on the calculated press-fitting length H3. The press-fitting method according to the embodiment makes it possible to manufacture each press-fit
 25 product C in which the dimensional accuracy of a portion that is set as a target portion is high even if any combination of the press-fitting component A and the press-fitting target component B having dimensional variations by managing the separation distance Ha

Fig. 2 is a block diagram of a manufacturing device 1 that performs the press-fitting
 30 method according to the embodiment. As shown in Fig. 2, the manufacturing device 1 includes a measuring portion ME, a press-fitting portion PR, an inspection portion 6, and a control portion 7. The measuring portion ME employed in the embodiment includes a first measuring portion 2 and a second measuring portion 3. The press-fitting portion PR employed

in the embodiment also includes a tentative press-fitting portion 4 (first press-fitting portion) and a press-fitting portion 5 (second press-fitting portion). In the manufacturing device 1, the measuring portion ME measures dimensions of the press-fitting component A and the press-fitting target component B. After a tentative press-fit product is produced by fitting the press-fitting component A with the press-fitting target component B tentatively by the press-fitting portion PR, a press-fit product C is manufactured by fitting the press-fitting component A of the tentative press-fit product with the press-fitting target component B at a prescribed position. Then the press-fit product C is measured.

The first measuring portion 2 includes a measurement instrument (not shown) for measuring the rotor shaft B (press-fitting target component B), and the measurement instrument measures a dimension of the rotor shaft B located at a prescribed measurement position. More specifically, the rotor shaft B is set at a measurement position by a transfer portion (not shown) or an operator and a length H1 of the shaft portion B1 of the rotor shaft B shown in Fig. 1 is measured by the measurement instrument of the first measuring portion 2.

The second measuring portion 3 includes a measurement instrument (not shown) for measuring the impeller A (press-fitting component A), and the measurement instrument measures a dimension of the impeller A located at a prescribed measurement position. More specifically, the impeller A is set at a measurement position by the transfer portion (not shown) or an operator and a length (thickness) H2 of the impeller A in the direction of the rotation axis Ax is measured by the measurement instrument of the second measuring portion 3.

The tentative press-fitting portion 4 includes a press-fitting apparatus (not shown) for press-fitting the impeller A (press-fitting component A) with the rotor shaft B (press-fitting target component B), and the impeller A that is set at a prescribed tentative press-fit position is press-fitted with the rotor shaft B to a tentative position. In the embodiment, the impeller A is moved by the press-fitting apparatus (i.e., the shaft portion B1 is inserted into the impeller A) to such an extent that the impeller A does not come off the rotor shaft B, to a tentative position of the shaft portion B1 of the rotor shaft B, whereby the impeller A (located at the tentative position) and the shaft portion B1 of the rotor shaft B are integrated with each other.

The control portion 7, which is, for example, a PLC (programmable controller),

includes a processing portion 71 such as a CPU, a storage portion 72 having a RAM, a ROM, etc., and an interface portion 73 that interfaces between the processing portion 71 and the devices outside the control portion 7. By running programs stored in the storage portion 72, the processing portion 71 performs processing corresponding to an operation of the manufacturing device 1. The storage portion 72 is stored with the programs to be run by the processing portion 71 and various kinds of data. The processing portion 71 communicates with the first measuring portion 2, the second measuring portion 3, the tentative press-fitting portion 4, the press-fitting portion 5, and the inspection portion 6 via the interface portion 73.

The control portion 7 records, in a first recording portion 11, first measurement information that is measurement information of the rotor shaft B measured by the first measuring portion 2. The control portion 7 records, in a second recording portion 12, second measurement information that is measurement information of the impeller A measured by the second measuring portion 3. The control portion 7 controls a press-fitting operation of the press-fitting portion 5 based on the pieces of measurement information obtained by the first measuring portion 2 and the second measuring portion 3. These operations will be described later in detail.

The press-fitting portion 5 includes a press-fitting device 10 for press-fitting the impeller A that is set at the prescribed press-fitting position with the rotor shaft B. Fig. 3 is a perspective view of the press-fitting device 10. As shown in Fig. 3, the press-fitting device 10 has a frame 21, a support portion 22, and a pressing mechanism 30. Figs. 3, 4, and 7 are perspective views of the press-fitting device 10 or its part as viewed from different directions. The upward, downward, leftward, rightward, forward, and backward directions to be used in the following description are denoted by respective symbols U, D, L, R, F, and B in Figs. 3, 4, and 7 (the leftward direction L and the rightward direction R are as viewed from the back side).

The frame 21 includes a frame main body 21a in which a pair of plate-like members are spaced from each other and portions of the plate-like members are connected to each other, a base portion 21b to which the frame main body 21a is fixed, a frame bottom portion 21c which is disposed at a low position in the frame main body 21a and provided with the support portion 22 which is disposed at a press-fitting position, and a frame top portion 21d which is disposed at the top of the frame main body 21a and provided with a pressing mechanism 30.

The support portion 22 is fixed to the frame bottom portion 21c and defines a press-fitting position. The support portion 22 includes a bottom end support portion 22a which supports the bottom end of the rotor shaft B so that it is not movable and a press-fitting holding mechanism 22b which holds the rotor shaft B (supported by the bottom end support portion 22a) so that its axis is parallel with the press-fitting direction. The bottom end of the rotor shaft B is brought into contact with the bottom end support portion 22a, whereby the bottom end support portion 22a determines one position (lower position) of the rotor shaft B in the press-fitting direction (top-bottom direction in Fig. 3) and restricts movement of the rotor shaft B. The press-fitting holding mechanism 22b includes a holding mechanism 22b1 which comes into contact with horizontal peripheral portions, perpendicular to the axis of the rotor shaft B, and holds the rotor shaft B and a holding drive portion 22b2 for moving the holding mechanism 22b1 to a holding position and a holding cancellation position.

In the embodiment, the shaft portion B1 of the rotor shaft B is mounted on and held by the support portion 22, whereby the rotor shaft B is supported at the press-fitting position while keeping a press-fit posture. More specifically, the rotor shaft B is supported by the support portion 22 in a state that the impeller A is press-fitted with the rotor shaft B at the tentative press-fitting position.

The frame top portion 21d is provided with the pressing mechanism 30. Fig. 4 is a perspective view showing the pressing mechanism 30. As shown in Fig. 4, the pressing mechanism 30 has a press-fitting drive portion 30a (see Fig. 3), a movable portion 31, and a press-fitting tool 32. The pressing mechanism 30 includes a pressure detecting means (not shown) for detecting a pressure state at the time of press fitting. The movable portion 31 is a rod-shaped member that extends in the press-fitting direction and has a prescribed length. The press-fitting drive portion 30a is attached and fixed to the frame top portion 21d so as to be able to move the movable portion 31 in the press-fitting direction. The movable portion 31 moves the press-fitting tool 32 between a press-fitting operation position where is set on one side in the press-fitting direction and a press-fitting standby position that is set over the press-fitting operation position by operation of the press-fitting drive portion 30a.

The pressing mechanism 30 can move the movable portion 31 in the top-bottom direction. Attached to the movable portion 31, the press-fitting tool 32 is moved in the top-

bottom direction together with the movable portion 31. The pressing mechanism 30 monitors, by means of the pressure detecting means, a pressure state during a press-fitting operation of the movable portion 31 being driven by the press-fitting drive portion 30a.

5 The press-fitting tool 32 has a pressing portion 33, restriction portions 34, and a position setting mechanism 40. The pressing portion 33 includes a pressing surface 33a to come into contact with the top surface A2 of the impeller A. When the press-fitting tool 32 is moved in the pressing direction (press-fitting direction), the pressing surface 33a of the pressing portion 33 comes into contact with the impeller A (press-fitting component A). When the
10 pressing surface 33a is moved in the pressing direction in a state that it is in contact with the impeller A, the impeller A is moved to a pressing completion position. In the embodiment, the pressing surface 33a comes into contact with the top surface A2 of the impeller A and pushes and moves it in the pressing direction, whereby the impeller A is moved to the pressing completion position.

15 When the press-fitting tool 32 is moved in the pressing direction, a restriction surface 34a of one of the restriction portions 34 comes into contact with the rotor shaft B (press-fitting target component B) and its movement in the press-fitting direction is thereby restricted. In the embodiment, when the press-fitting tool 32 is moved in the pressing direction, the restriction
20 surface 34a comes into contact with the top surface B4 of the shaft portion B1 of the rotor shaft B, whereby movement of the rotor shaft B in the press-fitting direction is restricted.

The position setting mechanism 40 sets a positional relationship between a position of the pressing surface 33a of the pressing portion 33 in the press-fitting direction and a position
25 of the restriction surface 34a of one of the restriction portions 34 in the press-fitting direction according to the impeller A (press-fitting component A) and the rotor shaft B (press-fitting target component B). In the embodiment, the press-fitting direction is the vertical direction.

The position setting mechanism 40 will be described below in detail. The position
30 setting mechanism 40 has a press-fitting jig 50 and a jig support unit 100.

Fig. 5 is a perspective view showing the press-fitting jig 50. As shown in Fig. 5, in the press-fitting jig 50, plural restriction portions 34 are arranged at prescribed intervals and a

movable body that is provided with the plural restriction portions 34 is provided so as to be movable in their arrangement direction. The press-fitting jig 50 employed in the embodiment has an axis that extends in a prescribed direction and is provided so as to be rotatable about the axis. The press-fitting jig 50 has a main body 51 having a prescribed length in the axial direction and shaped like a regular polygonal prism and an arrangement portion 52 that constitutes an outer circumferential surface of the main body 51. In the embodiment, the main body 51 is shaped like a regular decagonal prism.

The arrangement portion 52 constitutes the entire outer circumferential surface of the main body 51. The plural (an even number of) restriction portions 34 are arranged at regular intervals. The main body 51 is a member that is supported so as to be movable with respect to the pressing portion 33. In the embodiment, the center axis of the regular polygonal prism coincides with a rotation axis Bx. The press-fitting jig 50 is attached the press-fitting device 10 in a posture that the rotation axis Bx extends in a horizontal direction.

As shown in Fig. 4, the main body 51 is supported rotatably by the press-fitting tool 32. The arrangement portion 52 has plural flat surfaces 521 that are parallel with the rotation axis Bx. The flat surfaces 521 are arranged at prescribed intervals in the circumferential direction around the rotation axis Bx of the main body 51. As shown in Fig. 5, each flat surface 521 includes a maintaining/restricting portion 521a that is formed around a mounting portion 53 in which a restriction portion 34 is inserted and is used in restricting and maintaining rotation of the main body 51 which is supported rotatably. In the embodiment, the mounting portion 53 includes a hole that is formed in the flat surface 521 and a surface on which the associated restriction portion 34 is seated when it is attached. The mounting portion 53 is located at the center of the flat surface 521 and the maintaining/restricting portion 521a is formed around it. Each mounting portion 53 is coaxial with another mounting portion 53 that is line-symmetrical with the former mounting portion 53 when viewed from a point on the axis of the main body 51.

The main body 51 is provided with a rotation axis portion 54 that is formed with an insertion hole that penetrates through it at the center in the horizontal direction, that is, along the rotation axis Bx. A switching shaft portion 82 (described later) is inserted through and fixed to the insertion hole formed in the rotation axis portion 54. When the switching shaft

portion 82 is rotated, the press-fitting jig 50 is also rotated about the rotation axis Bx which extends in the horizontal direction (front-rear direction shown in Fig. 3).

Radial projection heights H4 of the respective restriction portions 34 which project in radial directions from the arrangement portion 52 are different from each other. One of the plural restriction portions 34 is selected according to a combination of an impeller A (press-fitting component A) and a rotor shaft B (press-fitting target component B), moved to the contact position by rotating the main body 51, and stopped (set) there.

Fig. 6 is a perspective view showing how each restriction portion 34 is attached to the main body 51 of the press-fitting jig 50. As shown in Fig. 6, the arrangement portion 52 is formed with a mounting portion 53 into which a restriction portion 34 is inserted. The restriction portion 34 is provided with a cylindrical height adjustment shaft portion 347 and an attachment leg (engagement portion 346) that is smaller in diameter than the height adjustment shaft portion 347 and is inserted in the mounting portion 53. The height adjustment shaft portion 347 has a restriction surface 34a to come into contact with the top surface B4 of the rotor shaft B, a seating surface 34c having a surface that is parallel with the restriction surface 34a, and an outer circumferential surface 34S located between the restriction surface 34a and the seating surface 34c. The lengths of the height adjustment shaft portions 347 in their axial directions (i.e., the directions of the center axes of the cylinders) of the respective restriction portions 34 are different from each other. In the following description, the axial length H4 of each height adjustment shaft portion 347 from the seating surface 34c to the restriction surface 34a may be referred to as a “projection height H4.”

The engagement portion 346 has a prescribed diameter and a prescribed length by which it projects in the axial direction from the seating surface 34c that is to come into contact with the associated flat surface 521 when each restriction portion 34 is attached to the mounting portion 53. Each restriction portion 34 is attached to the main body 51 of the press-fitting jig 50 detachably by engaging the engagement portion 346 of the restriction portion 34 with the hole of the associated mounting portion 53 of the press-fitting jig 50.

Returning to Fig. 4, the press-fitting device 10 includes a rotation mechanism 80 for rotating the press-fitting jig 50 about the rotation axis Bx and a switching drive source 8 that is

fixed to the frame 21 and causes the rotation mechanism 80 to operate. In the press-fitting device 10, when the rotation mechanism 80 operates, a desired one of the plural restriction portions 34 of the press-fitting jig 50 is selected and the restriction surface 34a of the selected restriction portion 34 is placed at such a position as to be able to touch the rotor shaft B (press-fitting target component B).

The rotation mechanism 80 has a switching drive portion 81 which is rotated by the switching drive source 8, the switching shaft portion 82 to which the main body 51 of the press-fitting jig 50 is fixed and which extends along the rotation axis Bx of the press-fitting jig 50, and a drive power transmission portion 83 for transmitting rotational power of the switching drive portion 81 to the switching shaft portion 82.

The frame 21 includes a switching fixing member 21e to which the switching drive source 8 is fixed. The switching drive source 8 is a motor for generating rotational torque. The switching drive portion 81 is a shaft portion that is rotated about a rotation axis Cx which extends in a horizontal direction (front-rear direction shown in Fig. 4) and is coupled to an output shaft of the switching drive source 8. The rotation axis Cx is set parallel with the rotation axis Bx of the press-fitting jig 50.

The drive power transmission portion 83 includes a first magnet body 831 which rotates together with the switching drive portion 81 and a second magnet body 832 which rotates in link with the rotation of the first magnet body 831 and transmits rotational power to the switching shaft portion 82. The first magnet body 831 is a cylindrical member in which N poles and S poles are arranged alternately in the circumferential direction around its central axis. The first magnet body 831 is provided at the tip of the switching drive portion 81 and is rotated together with the switching drive portion 81. In the embodiment, the first magnet body 831 is fixed to the tip of the switching drive portion 81 in such a manner that its center is located on the rotation axis Cx of the switching drive portion 81. The first magnet body 831 is disposed at a position corresponding to a press-fitting standby position where the press-fitting tool 32 stands by.

The second magnet body 832 is a cylindrical member in which N poles and S poles are arranged alternately in the circumferential direction around its central axis. The second

magnet body 832 is provided at the tip of the switching shaft portion 82 and is rotated as the first magnet body 831 rotates. In the embodiment, the second magnet body 832 is fixed to the tip of the switching shaft portion 82 in such a manner that its center is located on the rotation axis Bx that coincides with the center axis of the switching shaft portion 82. The second magnet body 832 is reciprocated in the press-fitting direction together with the press-fitting tool 32.

The first magnet body 831 which is provided on the switching drive portion 81 and the second magnet body 832 which is provided on the switching shaft portion 82 are arranged adjoining each other in such a range that a magnetic pole of one polarity of one of the first magnet body 831 and the second magnet body 832 attracts a magnetic pole of other polarity of the other of the first magnet body 831 and the second magnet body 832. Thus, the drive power transmission portion 83 can transmit rotational power of the switching drive source 8 to the switching shaft portion 82 as an N pole (or S pole) of the first magnet body 831 attracts and then repels an S pole (or N pole) of the second magnet body 832. That is, when the switching drive portion 81 is rotated by causing the switching drive source 8 to operate, rotational power of the switching drive portion 81 is transmitted to the press-fitting jig 50 via the drive power transmission portion 83 and the press-fitting jig 50 is rotated. Since drive power is transmitted through magnetic force, drive power of the first magnet body 831 can be transmitted to the second magnet body 832 through the magnetic force even if a gap exists between them.

In the embodiment, the switching shaft portion 82 is connected to the main body 51 of the press-fitting jig 50. Since the press-fitting jig 50 is provided on the movable portion 31, the switching shaft portion 82 can move in the top-bottom direction with respect to the frame 21. That is, as the press-fitting tool 32 moves in the top-bottom direction, the first magnet body 831 and the second magnet body 832 of the drive power transmission portion 83 come closer to or go away from each other. More specifically, when the press-fitting tool 32 is located at the press-fitting standby position, the first magnet body 831 and the second magnet body 832 are set adjoining each other. When the press-fitting jig 50 is moved downward from this state, the press-fitting jig 50 is made rotatable. When the press-fitting jig 50 is moved upward, rotation of the press-fitting jig 50 comes to be restricted.

Next, a mechanism for moving the press-fitting jig 50 in the top-bottom direction

with respect to a press-fitting movable body 90 will be described with reference to Figs. 4 and 7. Fig. 7 is a perspective view as viewed from the side that is opposite to the viewing side of Fig. 4 and includes the press-fitting jig 50 and the pressing mechanism 30. As shown in Figs. 4 and 7, the pressing mechanism 30 has the movable portion 31 which is moved to the press-fitting standby position and the press-fitting operation position that are set in the press-fitting direction when a press-fitting operation is performed. The press-fitting tool 32 has the press-fitting movable body 90 which is connected to the movable portion 31 and is moved together with it.

The press-fitting movable body 90 includes a connection portion 91, a pair of pressing link portions 90b (see Fig. 4), the pressing portion 33, a drive support portion 90a, and a guide portion 92. The connection portion 91 is provided on one side of the press-fitting movable body 90 in the press-fitting direction and connected to the movable portion 31. The pair of pressing link portions 90b are spaced from each other and project downward by a prescribed length from a bottom end portion of the connection portion 91. The pressing portion 33 is provided on the other side of the press-fitting movable body 90 in the press-fitting direction at the tips of the pair of pressing link portions 90b. The drive support portion 90a is provided on the connection portion 91 and supports a jig support unit 100 (described later). The guide portion 92 guides the jig support unit 100 (described later) in the press-fitting direction.

In the embodiment, the press-fitting movable body 90 is a cuboid member. The connection portion 91 is a top portion of the press-fitting movable body 90 and the pressing portion 33 is connected to a bottom portion of the press-fitting movable body 90. An elevation drive portion 102 for moving the jig support unit 100 in the press-fitting direction is connected to the drive support portion 90a. The guide portion 92 is a projection strip that is provided on a side surface of the press-fitting movable body 90 and extends in the top-bottom direction.

A pressing surface 33a of the pressing portion 33 of the press-fitting movable body 90 is formed with a hole 96 at such a position that it faces the restriction surface 34a (bottom surface) of one selected restriction portion 34 that is set at the restriction position. Thus, when the press-fitting movable body 90 is lowered, the pressing surface 33a of the pressing portion 33 that is provided as the bottom portion of the press-fitting movable body 90 pushes the impeller A and the shaft portion B1 of the rotor shaft B comes into contact with the restriction

surface 34a that is set at the restriction position through the hole 96 of the pressing surface 33a. A circumferential wall surface 33b (see Figs. 8 and 9) of the hole 96 of the pressing portion 33 restricts movement of the rotor shaft B in a radial direction that is perpendicular to the center axis of the rotor shaft B when the rotor shaft B is in contact with the restriction surface 34a.

5

The jig support unit 100 of the position setting mechanism 40 is attached to the press-fitting movable body 90 so as to be movable with respect to it in the press-fitting direction. The jig support unit 100 has a jig support portion 60 which supports the press-fitting jig 50 rotatably, a guide engagement portion 101, and the elevation drive portion 102. The guide engagement portion 101 is engaged with the guide portion 92 of the press-fitting movable body 90 and guides the jig support portion 60 in the top-bottom direction with respect to the press-fitting movable body 90.

In the illustrated example, the jig support portion 60 has a pair of support portions 60a that are adjacent to a pair of pressing link portions 90b (that provide a pair of side surfaces of the press-fitting movable body 90), respectively, and a connection portion 60b which connect the pair of support portions 60a. The pair of support portions 60a of the jig support portion 60 are equipped with a pair of switching support portions 60c, respectively, which support the switching shaft portion 82 rotatably. The switching support portions 60c are provided in the respective support portions 60a. The switching support portions 60c employed in the embodiment constitute respective bearing portions. The guide engagement portion 101 is a rail portion that is provided in the connection portion 60b (opposed to the guide portion 92) so as to extend in the top-bottom direction.

The elevation drive portion 102 is an actuator for moving the jig support unit 100 in the top-bottom direction with respect to the press-fitting movable body 90. The elevation drive portion 102 includes an elevation moving portion 102b which is connected to the drive support portion 90a and an elevation operation portion 102a which causes the elevation moving portion 102b to operate. The elevation moving portion 102b is formed so as to be able to protrude from and retract into the elevation operation portion 102a and is connected to the drive support portion 90a. The elevation operation portion 102a is fixed to the connection portion 60b so that the elevation moving portion 102b can protrude from and retract into the elevation operation portion 102a in the press-fitting direction. When operating to cause the elevation

moving portion 102b to protrude or retract, the elevation operation portion 102a comes closer to or goes away from the drive support portion 90a.

When the elevation drive portion 102 operates, the jig support unit 100 is moved in the top-bottom direction with respect to the press-fitting movable body 90 together with the elevation operation portion 102a because of the engagement between the guide portion 92 and the guide engagement portion 101. When the jig support unit 100 is moved, the press-fitting jig 50 is moved between a rotary movement possible position and a rotary movement restricted position that are set in the press-fitting movable body 90. When having moved to the rotary movement possible position, the press-fitting jig 50 can be rotated by causing the switching drive source 8 to operate in a state that the first magnet body 831 and the second magnet body 832 are set close to each other.

Next, a mechanism for placing one desired restriction portion 34 at such a position as to be able to touch the rotor shaft B (press-fitting target component B) will be described with reference to Figs. 8 and 9. Fig. 8 shows a state that the press-fitting jig 50 is rotatable. Fig. 9 shows a state that the press-fitting jig 50 is not rotatable. To facilitate understanding of the structure, Figs. 8 and 9 include sectional views of the press-fitting movable body 90 and the jig support unit 100 and a side view of the press-fitting jig 50.

As shown in Fig. 8, a housing portion 93 to house the press-fitting jig 50 is formed inside the press-fitting movable body 90. The housing portion 93 is formed by the pair of pressing link portions 90b which are located on the two respective sides of the housing portion 93 and opposed to each other, the pressing portion 33 which is located under the housing portion 93, and the connection portion 91 which is located over the housing portion 93. The connection portion 91 is provided with a rotation stop surface 94 for restricting rotation of the press-fitting jig 50 by coming into contact with a flat surface 521 of the arrangement portion 52 of the press-fitting jig 50.

Furthermore, the pair of pressing link portions 90b which are located on the two respective sides of the housing portion 93 are formed with respective insertion holes 95 through which the switching shaft portion 82 is inserted and which allow movement of the switching shaft portion 82 in the press-fitting direction. The insertion holes 95 are elongated holes having a prescribed length in the top-bottom direction.

A height dimension H93 of the housing portion 93 is larger than the maximum diameter of the main body 51 and is determined by the rotation stop surface 94 that defines one end, in the height direction, of the housing portion 93 and a pressing top surface 94L (of the pressing portion 33) that is the top surface of the pressing portion 33 and defines the other end, in the height direction, of the housing portion 93. A width dimension W93 of the housing portion 93 is larger than the width of the main body 51 and is determined by the confronting surfaces, defining the housing portion 93 from the two respective sides, of the pair of pressing link portions 90b.

As shown in Fig. 8, when the jig support unit 100 is moved downward with respect to the press-fitting movable body 90 and the press-fitting jig 50 is placed at the center of the housing portion 93 in the height direction, a flat surface 521, located at such a position as to be opposed to the rotation stop surface 94, of the press-fitting jig 50 is separated from the rotation stop surface 94 and the rotation unable state of the press-fitting jig 50 is canceled, that is, it is made rotatable. Since the press-fitting jig 50 is made rotatable, a desired one of the plural restriction portions 34 which are provided on the circumferential surface of the press-fitting jig 50 can be selected and positioned at the position where it is opposed to the pressing portion 33.

As shown in Fig. 9, when the jig support unit 100 is moved upward with respect to the press-fitting movable body 90 and the flat surface 521, located at such a position as to be opposed to the rotation stop surface 94, of the press-fitting jig 50 comes into contact with the rotation stop surface 94, the press-fitting jig 50 is made not rotatable. When the movable portion 31 is lowered in the state that the flat surface 521 of the press-fitting jig 50 is in contact with the rotation stop surface 94, the restriction portion 34, opposed to the pressing portion 33, of the press-fitting jig 50 comes into contact with the rotor shaft B (press-fitting target component B). The rotation stop surface 94 can receive, reliably, a reaction force that the press-fitting jig 50 receives from the rotor shaft B.

That is, when the press-fitting jig 50 is rotated so that a selected restriction portion 34 that is desired to be brought into contact with the rotor shaft B is located at the lowest position and the press-fitting jig 50 is moved upward in this state via the jig support unit 100, the selected restriction portion 34 is held in such a state as to be able to touch the rotor shaft B. In this manner, the position of the restriction surface 34a with respect to the rotation stop surface 94

can be selected from plural prescribed positions and thus set.

Returning to Fig. 7, the manufacturing device 1 according to the embodiment includes a mechanism that makes it possible to easily judge which one of the restriction portions 34 has been selected from the plural restriction portions 34. The position setting mechanism 40 has a discrimination body 41 for discriminating among the restriction portions 34 of the press-fitting jig 50. The discrimination body 41 has plural discrimination portions 42 corresponding to the respective restriction portions 34 of the press-fitting jig 50. The press-fitting device 10 includes a detection unit 43 capable of detecting each discrimination portion 42.

The discrimination body 41 is provided on the switching shaft portion 82 which supports the press-fitting jig 50. In the illustrated example, the discrimination body 41 is a disc-shaped member having a prescribed diameter. The discrimination body 41 is fixed to an end portion, opposite to an end portion provided with the second magnetic body 832, of the switching shaft portion 82 in such a manner that the center axis of the discrimination body 41 coincides with that of the switching shaft portion 82. That is, the discrimination body 41 rotates together with the press-fitting jig 50.

The plural discrimination portions 42 are provided in the same number as the plural restriction portions 34 of the press-fitting jig 50. The plural discrimination portions 42 have different pieces of discrimination information. For example, the discrimination portions 42 may be different marks or different pieces of magnetic information. The detection unit 43 may be a camera for taking an image of a discrimination portion 42 or a magnetic sensor for reading out magnetic information. In the embodiment, the plural discrimination portions 42 are discriminated from each other based on combinations of the number and positions of holes that are formed at prescribed intervals at respective positions where a radial line extending from the center of the discrimination body 41 perpendicularly to its center axis crosses circles that are formed at the same interval.

The detection unit 43 is fixed to the frame 21. The detection unit 43 includes a detection portion 43a for detecting a discrimination portion 42 and a detection portion attaching portion 43b which fixes the detection portion 43a to the frame 21. The detection portion 43a

detects a discrimination portion 42 when the press-fitting tool 32 is located at the press-fitting standby position. More specifically, the detection portion 43a is disposed so as to be able to detect one particular discrimination portion 42 in a state that the press-fitting tool 32 is located at the press-fitting standby position and the press-fitting jig 50 is rotatable. In the embodiment, settings are made so that when a selected restriction portion 34 is located at such a position as to be opposed to the pressing portion 33 the corresponding discrimination portion 42 is detected by the detection unit 43. An optical or magnetic rotary encoder may be employed as the detection mechanism consisting of the discrimination body 41, the discrimination portions 42, and the detection unit 43 to perform discrimination using a numerical value.

The press-fitting device 10 according to the embodiment is further equipped with a pressure sensor (not shown) capable of measuring a pressure that the movable portion 31 receives from the working target. The pressure sensor may be either provided in the connection portion 91 or incorporated in a press-fitting movement portion 31a. The pressure sensor outputs information relating to a measured pressure to the control portion 7.

<Press-fitting method and manufacturing method>

Next, a press-fitting method using the press-fitting device 10 according to the embodiment and a manufacturing method of a press-fit product C using it will be described with reference to Figs. 10A-10D. Figs. 10A-10D are diagrams schematically showing positional relationships between the impeller A (press-fitting component A), the rotor shaft B (press-fitting target component B), and the press-fitting tool 32 in respective manufacturing steps. In Figs. 10A-10D, the impeller A (press-fitting component A) is drawn as a cuboid component and the jig support unit 100 is omitted.

The manufacturing method according to the embodiment includes:

a preparing step of preparing a press-fitting component A and a press-fitting target component B; and

a press-fitting step of press-fitting one of the press-fitting component A and the press-fitting target component B into or with the other by moving the one of the press-fitting component A and the press-fitting target component B in the press-fitting direction by means of the press-fitting tool 32.

The preparing step has a setting step of setting the press-fitting component A or the press-fitting target component B in the measuring portion ME of the manufacturing device 1. The preparing step includes a second measuring step of measuring a dimension of the press-fitting component A after the setting step and a first measuring step of measuring a dimension of the press-fitting target component B. In the embodiment, the first measuring step is executed by the first measuring portion 2 which is included in the measuring portion ME and the second measuring step is executed by the second measuring portion 3 which is included in the measuring portion ME.

The press-fitting step press-fits the press-fitting component A with the press-fitting target component B by the press-fitting portion PR of the manufacturing device 1. The press-fitting step includes a tentative press-fitting step of press-fitting the press-fitting component A with the press-fitting target component B to a tentative press-fitting position of the press-fitting target component B and a press-fitting step of press-fitting the press-fitting component A being in a tentative press-fit state with the press-fitting target component B to a press-fitting completion position. In the embodiment, the tentative press-fitting step, which is executed by the by the tentative press-fitting portion 4 of the press-fitting portion PR, press-fits the press-fitting component A with the press-fitting target component B tentatively to establish a tentative press-fit state in which the press-fitting component A is integrated with the press-fitting target component B tentatively (see states of the press-fitting component A and the press-fitting target component B shown in Fig. 10A).

As shown in Fig. 10B, the press-fitting step, which is executed by the press-fitting portion 5 of the press-fitting portion PR, press-fits the press-fitting component A being in a tentative press-fit state with the press-fitting target component B to the press-fitting completion position. The press-fitting step adjusts the press-fitting interval dimension HT (see Fig. 9) in the press-fitting direction between the pressing surface 33a of the pressing portion 33 and the restriction surface 34a of a restriction portion 34 so as to obtain a press-fitting stop position of the press-fitting component A that is set in the press-fitting target component B according to related dimensions of the press-fitting component A and the press-fitting target component B (press-fitting stop position adjusting step).

In the embodiment, first, the control portion 7 selects one proper restriction portion 34 from the plural restriction portions 34 based on a first dimension H1 and a second dimension

H2. Then the control portion 7 adjusts the press-fitting interval dimension HT by rotating the press-fitting jig 50 so that the selected restriction portion 34 is placed at a confronting position where it is opposed to the pressing portion 33 when the press-fitting tool 32 is located at the press-fitting standby position that is spaced upward from the press-fitting component A that is set over the support portion 22. The control portion 7 moves the press-fitting jig 50 upward relative to the press-fitting movable body 90 in a state that the selected restriction portion 34 is located at the confronting position where it is opposed to the pressing portion 33. As a result, the arrangement portion 52 of the press-fitting jig 50 comes into contact with the rotation stop surface 94. This will be described in detail later.

Furthermore, as shown in Fig. 10C, the press-fitting component A is press-fitted with the press-fitting target component B (press-fitting step). The control portion 7 lowers the movable portion 31 so that the pressing portion 33 comes into contact with the top surface A2 of the press-fitting component A. In the illustrated example, since the pressing surface 33a of the pressing portion 33 is located under the restriction surface 34a of the restriction portion 34, the pressing surface 33a comes into contact with the top surface A2 of the press-fitting component A before the restriction surface 34a comes into contact with the top surface B4 of the press-fitting target component B. The control portion 7 continues to lower the movable portion 31 until the restriction surface 34a comes into contact with the top surface B4 of the press-fitting target component B and causes the pressing surface 33a to continue to press-fit the press-fitting component A with the press-fitting target component B.

Still further, as shown in Fig. 10D, the restriction portion 34 comes into contact with the press-fitting target component B, whereupon the press-fitting of the press-fitting component A with the press-fitting target component B is stopped (press-fitting completion step). When detecting that the restriction surface 34a has come into contact with the top surface B4 of the press-fitting target component B, the control portion 7 stops the lowering of the movable portion 31 and stops the operation of press-fitting the press-fitting component A with the press-fitting target component B.

Incidentally, in the embodiment, the pressing mechanism 30 includes the pressure sensor for measuring a pressure produced by a press-fitting operation of the movable portion 31. Fig. 11 is a graph showing a variation of an output value of the pressure sensor with

respect to the lowering distance of the movable portion 31. The horizontal axis of Fig. 11 represents the lowering distance of the movable portion 31 and its vertical axis represents the output value (the pressure value) of the pressure sensor. Symbol X1 on the horizontal axis indicates a contact-to-pressing-surface position (first press-fitting operation position) corresponding to a movement distance (lowering distance) by which the movable portion 31 has moved from the initial position (press-fitting standby position) to such a position that the pressing surface 33a comes into contact with the press-fitting component A. Symbol X2 indicates a contact-to-restriction-surface position (second press-fitting operation position) corresponding to a movement distance (lowering distance) by which the movable portion 31 has moved from the press-fitting standby position to such a position that the restriction surface 34a comes into contact with the press-fitting target component B.

While the movable portion 31 is lowered from the initial position (the lowering distance is equal to 0) to the contact-to-pressing-surface position X1, the pressing surface 33a is not in contact with the top surface A2 of the impeller A and the restriction surface 34a is not in contact with the top surface B4 of the rotor shaft B. In this state, the movable portion 31 (press-fitting tool 32) does not receive any reaction force from the working target and hence the output value of the pressure sensor is equal to 0. As the movable portion 31 is then lowered from the contact-to-pressing-surface position X1 toward the contact-to-restriction-surface position X2, the pressing surface 33a comes to touch the top surface A2 of the impeller A, whereupon the output value of the pressure sensor reaches a first threshold value P1. As the movable portion 31 is lowered further, the restriction surface 34a comes to touch the top surface B4 of the shaft portion B1 of the rotor shaft B, whereupon the output value of the pressure sensor quickly increases to a second threshold value P2 that is larger than the first threshold value P1. When the control portion 7 which receives the output value of the pressure sensor judges that the output value of the pressure sensor has reached the second threshold value P2, the control portion 7 stops the lowering of the movable portion 31.

As described above, the press-fitting operation can be stopped when the movable portion 31 has reached the contact-to-restriction-surface position X2 (i.e., the restriction surface 34a has reached the top surface B4 of the shaft portion B1 of the rotor shaft B). Where the first threshold value P1 (first pressure value) and the second threshold value P2 (second pressure value) are stored in the storage portion 72 of the control portion 7, the control portion

7 can perform pressure monitoring, that is, an operation of comparing an operation pressure value that is output from the pressure sensor in operation and received by the control portion 7 with the first pressure value and the second pressure value.

As described above, the press-fitting method according to the embodiment includes
 5 a pressure detecting step of detecting that the pressure acting on the press-fitting tool 32 has reached a preset, prescribed value.

The press-fitting stop position adjusting step shown in Fig. 10C will be described in detail below.

10 The press-fitting stop position adjusting step includes a press-fitting interval setting step of setting a press-fitting interval dimension HT so that an absolute value of the difference between a preset reference interval dimension Ha to be managed and an actual value of the reference interval dimension Ha of a press-fit product C manufactured using the press-fitting interval dimension HT becomes smaller than a predetermined allowable error value.

15 The press-fitting stop position is a stop position of the press-fitting component A that is fitted with the press-fitting target component B and is a position in the press-fitting direction (vertical direction) where the restriction surface 34a has come into contact with the press-fitting target component B.

20 The press-fitting interval dimension HT is the interval between the pressing surface 33a and the restriction surface 34a, that is, the interval between a press-fitting stop position of the pressing surface 33a and the press-fitting stop position of the restriction surface 34a. As shown in Fig. 9, in the embodiment, the press-fitting interval dimension HT is the difference between a dimension HR from the rotation stop surface 94 to the pressing surface 33a and a
 25 dimension HS from one flat surface 521 of the press-fitting jig 50 to the restriction surface 34a of the restriction portion 34 provided on the other flat surface 521 opposed to the pressing portion 33 in a state that the one flat surface 521 of the press-fitting jig 50 is in contact with the rotation stop surface 94.

That is, the press-fitting stop position is not changed by movement of the movable
 30 portion 31 in the top-bottom direction. The press-fitting interval dimension HT does not vary when the movable portion 31 is moved in the top-bottom direction, either. In the embodiment, the press-fitting stop position and the press-fitting interval dimension HT change when one of the plural restriction portions 34 having different heights of the press-fitting jig 50 is selected

as a restriction portion 34 having a restriction surface 34a.

In the above-described manufacturing device 1, the pressing surface 33a is the lower end surface of the press-fitting movable body 90 and is moved together with the movable portion 31. The pressing surface 33a and the movable portion 31 are always moved together. Thus, the interval between the rotation stop surface 94 (reference surface) and the pressing surface 33a is always the same.

On the other hand, the plural restriction portions 34 are provided on the press-fitting jig 50 which is supported rotatably by the press-fitting movable body 90. The restriction surface 34a of selected one of the plural restriction portions 34 is placed so as to be opposed to the pressing portion 33. In this manner, the press-fitting stop position can be changed by switching the restriction surface 34a to be opposed to the pressing portion 33 to one having a different height by rotating the press-fitting jig 50. That is, the interval between the rotation stop surface 94 (reference surface) and the restriction surface 34a opposed to the pressing portion 33 varies depending on which restriction surface 34a is selected.

Thus, the press-fitting interval dimension HT which is the interval between the pressing surface 33a and the restriction surface 34a opposed to the pressing portion 33 can be changed by setting one of the plural restriction surfaces 34a at such a position as to be opposed to the pressing portion 33 by rotating the press-fitting jig 50. That is, in the embodiment, the restriction position, in the press-fitting direction, of the restriction portion 34 can be set according to the press-fitting component A and the press-fitting target component B by changing the combination of the dimension between the pair of flat surfaces 521 that are line-symmetrical with respect to the center axis of the press-fitting jig 50 and the projection height dimension H4 of the restriction portion 34 to be set so as to be opposed to the pressing portion 33 by rotating the press-fitting jig 50 by the position setting mechanism 40.

For example, in the example shown in Fig. 10B, the press-fitting jig 50 is located over the pressing surface 33a. Even in a case that the restriction portion 34 having a largest projection height H4 is located on the side of the pressing surface 33a, the restriction surface 34a is located over the pressing surface 33a. In this configuration, a first press-fitting interval dimension HT of a case that a restriction portion 34 having a large projection height H4 is

located on the side of the pressing surface 33a is shorter than a second press-fitting interval dimension HT of a case that a restriction portion 34 having a small projection height H4 is located on the side of the pressing surface 33a.

Fig. 12 is a schematic diagram showing the impeller A (press-fitting component A), the rotor shaft B (press-fitting target component B), and the press-fitting jig 50 immediately after completion of the press-fitting step. Fig. 12 corresponds to Fig. 10D. As shown in Fig. 12, in this state, the pressing surface 33a is in contact with the top surface A2 of the impeller A and the restriction surface 34a is in contact with the top surface B4 of the shaft portion B1 of the rotor shaft B.

The length of the portion, from a step surface B3a of the rotor shaft B to the top surface B4 of its shaft portion B1, of the shaft portion B1 is called the first dimension H1. The first measuring portion 2 performs measurements including the first dimension H1.

The length of the impeller A along its rotation axis Ax is called the second dimension H2. The second measuring portion 3 performs measurements including measurement of the second dimension H2.

In the embodiment, the dimension that should be managed is the dimension Ha from the step surface B3a to the bottom surface A3 of the impeller A. When a press-fit product C is designed, a value of the dimension Ha is set. The value, set at the time of designing the press-fit product C, of the dimension Ha is called a “reference interval dimension Ha.” In the embodiment, it is desired to manufacture a press-fit product C so that its value of this dimension becomes as close to the reference interval dimension Ha as possible. The reference interval dimension Ha is input to and stored in the storage portion 72 of the control portion 7 before execution of a press-fitting step.

In every industrial product, an allowance (allowable error value) is set for each dimension. Also in a press-fit product C to be manufactured by the press-fitting device 10 according to the embodiment, a difference may occur between the reference interval dimension Ha that was set at the time of designing and an actual value of this dimension of a press-fit product C manufactured using the press-fitting device 10. The manufactured press-fit product C is judged a good product if an absolute value of the difference is within an allowable error value. On the other hand, the manufactured press-fit product C is judged a defective product

if the absolute value of the difference is larger than the allowable error value.

Incidentally, as seen from Fig. 12, the sum of the third dimension H3 from the top surface B4 of the shaft portion B1 of the rotor shaft B to the top surface A2 of the impeller A, the second dimension H2 from the top surface A2 to the bottom surface A3 of the impeller A, and the reference interval dimension Ha is equal to the first dimension H1 which is the length from the step surface B3a of the rotor shaft B to the top surface B4 of its shaft portion B1. That is, a relationship $H3 + H2 + Ha = H1$ holds. Whereas the reference interval dimension Ha, the first dimension H1, and the second dimension H2 have unique, fixed values, the third dimension H3 is an adjustable, variable value. By modifying the above equation, a relationship $H3 = H1 - H2 - Ha$ is obtained, according to which a third dimension H3 can be calculated which is a variable value.

In this press-fitting method, to perform press-fitting so that the reference interval dimension Ha is kept equal to a prescribed value even if the first dimension H1 and the second dimension H2 vary, the position of the impeller A in the press-fitting direction is controlled by the press-fitting tool 32. For example, where a second press-fit product CB is manufactured after a first press-fit product CA, there may occur an event that the second dimension H2 of the impeller A of the second press-fit product CB is larger than that of the impeller A of the first press-fit product CA due to, for example, a variation of that dimension of the component.

In this case, when the second press-fit product CB is manufactured, the reference interval dimension Ha at the time of manufacture of the second press-fit product CB can be made equal to that at the time of manufacture of the first press-fit product CA by adjusting the third dimension H3 so that it becomes smaller than that at the time of manufacture of the first press-fit product CA.

The third dimension H3 is a dimension that is obtained when the pressing surface 33a presses the top surface A2 of the impeller A and the restriction surface 34a comes into contact with the top surface B4 of the shaft portion B1 of the rotary shaft B. Furthermore, as described above, the press-fitting interval dimension HT is an interval dimension between the press-fitting stop position of the pressing surface 33a and the press-fitting stop position of the restriction surface 34a, the interval dimension being set according to the third dimension H3 that is set by the pressing mechanism 30 in the press-fitting step to obtain the reference interval dimension

Ha. That is, the reference interval dimension Ha can be made equal to a desired value by setting the press-fitting interval dimension HT equal to the third dimension H3.

In the press-fitting method according to the embodiment, the press-fitting position adjusting step includes an interval calculating step of calculating a press-fitting interval dimension HT based on the first dimension H1 which is a length of the press-fitting target component B in the press-fitting direction, the second dimension H2 which is a length of the press-fitting component A in the press-fitting direction, and the reference interval dimension Ha.

In the embodiment, the press-fitting interval dimension HT can be set at a value that is close to the third dimension H3 by selecting one proper restriction portion 34 from the plural restriction portions 34 that are different from each other in the projection height H4.

For example, where the first dimension H1 is 20.000 mm, the second dimension H2 is 9.979 mm, and the reference interval dimension Ha is 10.000 mm, the third dimension H3 is calculated as follows: $20.000 - 9.979 - 10.000 = 0.021$ mm. In this case, a restriction portion 34 is selected that makes the press-fitting interval dimension HT closest to 0.021 mm.

In the following, a method for selecting a restriction portion 34 so as to obtain a press-fitting interval dimension HT that makes a press-fit product C manufactured by press-fitting the impeller A with the rotor shaft B have a reference interval dimension Ha value that is closest to the intended reference interval dimension Ha.

Fig. 13 is a table of sets of pieces of information of plural restriction portions 34 of the press-fitting device 10. In this example, it is assumed that the difference between the press-fitting stop position of the flat surface 521 opposed to the pressing portion 33 and the press-fitting stop position of the pressing surface 33a is equal to 10.000 mm. And a position of the restriction surface 34a is given a positive value if it is located under the pressing surface 33a and is given a negative value if it is located over the pressing surface 33a.

The projection height H4 of a first restriction portion 341 is 10.040 mm, and hence the difference (press-fitting interval dimension HT) between the restriction surface 34a of the first restriction portion 341 and the pressing surface 33a is equal to 0.040 mm.

The projection height H4 of a second restriction portion 342 is 10.020 mm, and hence

the press-fitting interval dimension HT is equal to 0.020 mm.

The projection height H4 of a third restriction portion 343 is 10.000 mm, and hence the press-fitting interval dimension HT is equal to 0.000 mm.

5 The projection height H4 of a fourth restriction portion 344 is 9.980 mm, and hence the press-fitting interval dimension HT is equal to -0.020 mm.

The projection height H4 of a fifth restriction portion 345 is 9.960 mm, and hence the press-fitting interval dimension HT is equal to -0.040 mm.

10 In the above-described example, the press-fitting interval dimension HT is desired to be set at 0.021 mm. Thus, among the first restriction portion 341 to the fifth restriction portion 345, the second restriction portion 342 provides a press-fitting interval dimension HT that is closest to 0.021 mm. In this example, the control portion 7 selects the second restriction portion 342.

15 In the embodiment, the projection heights H4 of the respective restriction portions 34 are set taking an allowable error value into consideration. That is, the restriction portions 34 are designed so that their projection heights H4 change stepwise with an interval 0.02 mm. Thus, the range of the press-fitting interval dimension HT in which the first restriction portion 341 can be used is from 0.030 mm (inclusive) to 0.050 mm (not inclusive). The range of the
20 press-fitting interval dimension HT in which the second restriction portion 342 can be used is from 0.010 mm (inclusive) to 0.030 mm (not inclusive). The range of the press-fitting interval dimension HT in which the third restriction portion 343 can be used is from -0.010 mm (inclusive) to 0.010 mm (not inclusive). The range of the press-fitting interval dimension HT in which the fourth restriction portion 344 can be used is from -0.030 mm (inclusive) to -0.010
25 mm (not inclusive). The range of the press-fitting interval dimension HT in which the fifth restriction portion 345 can be used is from -0.050 mm (inclusive) to -0.030 mm (not inclusive).

In this example, the press-fitting interval dimension HT is set at 0.020 mm. If press-fitting is performed using the press-fitting tool 32 in which the second restriction portion 342
30 is selected, an actual value of the reference interval dimension Ha of a manufactured press-fit product becomes $20.000 - 9.979 - 0.020 = 10.001$ mm. Whereas the reference interval dimension Ha is desired to be 10.000 mm, the actual value is 10.001 mm; that is, there occurs a difference 0.001 mm. However, in this example, since the allowable error value is set at

0.010 mm, the press-fit product C manufactured by performing press-fitting working using the second restriction portion 342 is judged a good product.

Whereas the press-fitting jig 50 employed in the embodiment is provided with the 10 restriction portions 34, the above example was described for the case that the five restriction portions 34 exist. Thus, in the above example using the five restriction portions 34, an absolute value of the difference between the reference interval dimension H_a and an actual value can fall within the allowable error value 0.010 mm if the third dimension H_3 is larger than or equal to -0.050 mm and smaller than 0.050 mm.

10 The specific values of the respective members and portions used in the above example are just for description and the values of those members and portions are not limited to those values.

As described above, in the press-fitting method according to the embodiment, the 15 pressing portion 33 has the single pressing surface 33a and the press-fitting jig 50 has the plural restriction surfaces 34a that are provided in advance at prescribed intervals. The press-fitting method includes a restriction surface selecting step of selecting one of the plural restriction surfaces 34a so as to obtain a press-fitting stop position that is suitable for a press-fitting interval dimension H_T that is set according to dimensions of the press-fitting component A and the 20 press-fitting target component B.

The press-fitting stop position adjusting step includes a press-fitting interval determining step of placing the pressing portion 33 and a selected restriction portion 34 at prescribed positions in the press-fitting tool 32 that make the difference between the press- 25 fitting stop position of the pressing surface 33a of the pressing portion 33 and the press-fitting stop position of the restriction surface 34a of the restriction portion 34 equal to the press-fitting interval dimension H_T that has been set by the press-fitting interval setting step.

More specifically, after selecting, for example, the second restriction portion 342 (as in the above example), the control portion 7 rotates the press-fitting jig 50 so that the selected 30 second restriction portion 342 is located at such a position as to be opposed to the pressing portion 33. When the movable portion 31 is lowered in this state, first the pressing portion 33 comes into contact with the top surface A2 of the impeller A. When the movable portion 31 is lowered further, the impeller A is press-fitted with the rotor shaft B gradually by the pressing

portion 33. When the movable portion 31 is lowered further after the pressing portion 33 came into contact with the top surface A2 of the impeller A, the restriction portion 34 comes into contact with the top surface B4 of the shaft portion B1 of the rotor shaft B. If judging that the restriction portion 34 has come into contact with the top surface B4 of the shaft portion B1 of the rotor shaft B, the control portion 7 stops the lowering of the movable portion 31. Since the second restriction portion 342 was selected in advance so that the press-fitting interval dimension HT becomes closest to the third dimension H3 and the press-fitting operation is restricted by the second restriction portion 342, the dimensional accuracy of the reference interval dimension Ha can be made within the range of the allowable error value.

As shown in Fig. 10B, if judging, before a start of a press-fitting step, that the restriction portion 34 opposed to the pressing portion 33 is not the selected restriction portion 34, the control portion 7 switches the restriction portion 34 by rotating the press-fitting jig 50 so that the selected restriction portion 34 comes to be opposed to the pressing portion 33. That is, the press-fitting stop position adjusting step includes a switching step of switching at least one of the pressing surface 33a and the restriction surface 34a to a selected one.

Incidentally, the manufacturing method according to the embodiment includes a press-fit product C inspecting step of measuring a completion interval dimension that is an interval in the press-fitting direction between a prescribed position of the press-fitting target component B, press-fitted in the press-fitting step, of a press-fit product C and a prescribed position of the press-fitting component A (in the above example, an actual dimension from the step surface B3a of the rotor shaft B and to the bottom surface A3 of the impeller A) and comparing the measured completion interval dimension with the reference interval dimension Ha.

Whether the manufactured press-fit product C is good or defective can be judged by carrying out an inspection to check whether the dimension (completion interval dimension) corresponding to the reference interval dimension Ha of the manufactured press-fit product C. In the above example, the press-fit product C is judged good if the completion interval dimension is in a range of $10.000 \text{ mm} \pm 0.010 \text{ mm}$ and is judged defective if it is out of that range.

As described above, the press-fitting device 10 according to the embodiment is a

press-fitting device for press-fitting a press-fitting component A with a press-fitting target component B, comprising:

the support portion 22 which supports the press-fitting target component B; and

the pressing mechanism 30 having the press-fitting tool 32 capable of moving in the

5 press-fitting direction with respect to the support portion 22, wherein:

the press-fitting tool 32 comprises:

the pressing portion 33 which presses the press-fitting component A by
the pressing surface 33a;

10 the restriction portion 34 having the restriction surface 34a capable of
coming into contact with the press-fitting target component B; and

the position setting mechanism 40 which sets a press-fitting position of
the pressing surface 33a of the pressing portion 33 in the press-fitting direction and a
restriction position of the restriction surface 34a of the restriction portion 34 in the press-
fitting direction according to the press-fitting component A and the press-fitting target
15 component B.

In the press-fitting device 10 according to the embodiment, a pressing position and
a restriction position that are suitable for dimensions of the press-fitting component A and the
press-fitting target component B are set. Thus, press-fitting stop positions can be made close
20 to each other when press-fitting components A are press-fitted with respective press-fitting
target components B, the press-fitting components A and the press-fitting target components B
having different sets of dimensions. The press-fitting device 10 according to the
embodiment can manufacture a press-fit product C quickly with high accuracy because the
press-fitting tool 32 in which a pressing portion 33 and a restriction portion 34 suitable for
25 dimensions of the press-fitting component A and the press-fitting target component B are set
performs working unlike in the case of Patent document 1 in which a lowering position of the
movable portion 31 is controlled according to a sensor output.

The above-described embodiment is directed to the press-fitting device 10 in which
30 the single pressing portion 33 and the plural restriction portions 34 are provided, the restriction
position of the restriction surface 34a in the press-fitting direction is variable, and the pressing
position of the pressing surface 33a in the press-fitting direction is fixed. However, the
invention is not limited to this configuration. The press-fitting device 10 may be configured

in such a manner that it includes plural pressing portions 33 and a single restriction portion 34 and one of the plural pressing portions 33 is selected to obtain a proper press-fitting interval dimension HT. In this case, the pressing position is variable and the restriction position is fixed. As a further alternative, the press-fitting device 10 may be configured in such a manner that it includes plural pressing portions 33 and plural restriction portions 34 and a set of a pressing portion 33 and a restriction portion 34 is selected to obtain a proper press-fitting interval dimension HT. In this case, the pressing position and the restriction position are both variable.

Although in the above-described embodiment the press-fitting component A is an impeller and the press-fitting target component B is a rotor shaft, the invention can also be applied to a case of press-fitting a rotor shaft into an impeller. Furthermore, the invention can be applied to manufacture of press-fit products other than press-fit products composed of an impeller and a rotor shaft.

Although in the above-described embodiment the press-fitting direction is the vertical direction, the invention is not limited to this case. The invention can be applied irrespective of the press-fitting direction; for example, the press-fitting direction may be a horizontal direction.

The press-fitting device 10 according to the embodiment may be such that:
the position setting mechanism 40 comprises the press-fitting jig 50 in which the plural restriction portions 34 are arranged at a prescribed interval and which is provided so as to be able to move in the arrangement direction of the plural restriction portions 34; and

the press-fitting jig 50 comprises:
the arrangement portion 52 in which the plural restriction portions 34 are arranged at the prescribed interval; and
the main body 51 which is provided with the arrangement portion 52 and is supported so as to be movable with respect to the pressing portion 33.

In this press-fitting device 10 according to the embodiment, since the press-fitting jig 50 can be moved in the arrangement direction of the plural restriction portions 34, switching to a selected restriction portion 34 can be made more quickly than in a

configuration in which unlike in the embodiment switching is made each time to a selected one of plural restriction portions 34 that are prepared separately.

The press-fitting device 10 according to the embodiment may be such that:

the arrangement portion 52 is provided with the mounting portions 53 in which the plural respective restriction portions 34 are mounted; and

each of the plural restriction portions 34 is provided with an engagement portion 346 that is engaged with an associated mounting portion 53.

In this press-fitting device 10 according to the embodiment, each restriction portion 34 is attached to the main body 51 in a replaceable manner. Thus, even in a case of working on a press-fitting component A and a press-fitting target component B having such dimensions that none of the restriction portions 34 already attached in the press-fitting device 10 can accommodate, press-fitting can be performed by attaching a new restriction portion 34 to the main body 51.

Although in the above-described embodiment each restriction portion 34 is fitted in the associated mounting portion 53 (see Fig. 6), the invention is not limited to this case. A press-fitting jig 50 may be configured as shown in Figs. 14A and 14B or Fig. 15. Figs. 14A and 14B show a press-fitting jig 150 according to a first modification. Fig. 15 shows a press-fitting jig 250 according to a second modification.

In the first modification shown in Fig. 14A, each restriction portion 134 is composed of a cylindrical portion 134c having a restriction surface 134a and a shim plate 134b which is sandwiched between the cylindrical portion 134c and a flat surface 521. The cylindrical portions 134c of the respective restriction portions 134 have the same height $H4a$ (measured along the rotation-symmetry axis of each cylindrical portion 134c) (see Fig. 14B). The shim plates 134b of the respective restriction portions 134 have different thicknesses $H4b$ (see Fig. 14B). Each restriction portion 134 is attached to a main body 151 by insertion of the shim plate 134b between cylindrical portion 134c and the flat surface 521. The projection height $H4'$ of the restriction surface 134a from the flat surface 521 varies depending on the thickness of the shim plate 134b.

In the second modification shown in Fig. 15, each restriction portion 234 is composed of a cylindrical portion 234c having a restriction surface 234a and a screw portion (not shown) that projects from the bottom surface of the cylindrical portion 234c. A mounting portion 253 is a screw hole. Each restriction portion 234 can be replaced easily by screwing a restriction portion 234 into the mounting portion 253, without changing a main body 251 of the press-fitting jig 250.

The press-fitting device 10 according to the embodiment may be such that:

the main body 51 is supported rotatably in the press-fitting tool 32; and

the arrangement portion 52 has the plural flat surfaces 521 that are arranged at a prescribed interval in the circumferential direction around the rotation axis Bx of the main body 51 and extend parallel with the rotation axis Bx, and the plural flat surfaces 521 are provided with the plural respective mounting portions 53.

In this press-fitting device 10 according to the embodiment, the press-fitting jig 50 is rotatable and the restriction portions 34 are arranged in the circumferential direction around the rotation axis Bx. Thus, switching to a selected restriction portion 34 can be made by a simple operation of rotating the press-fitting jig 50.

The press-fitting device 10 according to the invention is not limited to the case that the arrangement portion 52 has the plural flat surfaces 521 that extend parallel with the rotation axis Bx. Fig. 16 is an exploded perspective view showing a press-fitting jig 350 according to a third modification of the invention. As shown in Fig. 16, the press-fitting jig 350 according to the third modification includes a disc-shaped main body 351 and plural pressing portions 333. A press-fitting device 310 according to the third modification includes one restriction portion 334 and the plural pressing portions 333. The restriction position is fixed and the pressing position is variable. The rotation axis Bx of the press-fitting jig 350 extends in the vertical direction.

The plural pressing portions 333 are provided on respective crossing points of a circle that is set on the main body 351 of the press-fitting jig 350 and radial lines that are perpendicular to the rotation axis Bx. The pressing portions 333 are arranged at prescribed intervals on a circle around the rotation axis Bx. One desired pressing portion 333 can be placed at such a position as to be able to touch the press-fitting component A by rotating this press-fitting jig

350 about the rotation axis Bx.

Fig. 17 is a sectional view of the press-fitting jig 350 according to the third modification shown in Fig. 16. Fig. 17 shows a state that the restriction portion 334 is in contact with the press-fitting target component B. A hole 333b penetrates through each pressing portion 333 at its center in the top-bottom direction. The hole 333b is composed of a lower, small-diameter hole and an upper, large-diameter hole and a boundary surface 333c is formed at their boundary. The inner diameter of the large-diameter hole is larger than the outer diameter of the restriction portion 334 and the inner diameter of the small-diameter hole is smaller than the outer diameter of the restriction portion 334. When the restriction portion 334 is lowered from a position located above, it comes into contact with the boundary surface 333c, a relative positional relationship between the restriction portion 334 and the selected pressing surface 333d is set. The length from a bottom surface 333d of the pressing portion 333 to the boundary surface 333c becomes a press-fitting interval dimension HT. When the restriction portion 334 is lowered further, it lowers the pressing portion 333 and the main body 351 together with it and can press-fit the press-fitting component A with the press-fitting target component B.

The plural pressing portions 333 are different from each other in the length from the bottom surface 333d to the boundary surface 333c. Thus, a pressing portion 333 having a press-fitting interval dimension HT to be set can be placed at such a position as to be able to touch the press-fitting component A by rotating the disc-shaped main body 351.

Although the embodiment of the invention has been described above, it goes without saying that the technical scope of the invention should not be construed restrictively by the description of the embodiment. It would be understood by those skilled in the art that the embodiment is just an example and can be modified in various manners within the confines of the invention as set forth in the claims. The technical scope of the invention should be determined on the basis of the scope of the invention as set forth in the claims and its equivalents.

WHAT IS CLAIMED IS:

1. A press-fitting device for press-fitting a press-fitting component with a press-fitting target component, comprising:

5 a support portion which supports the press-fitting target component; and
a pressing mechanism having a press-fitting tool configured to move in a press-fitting direction with respect to the support portion, wherein:

the press-fitting tool comprises:

10 a pressing portion having a pressing surface which presses the press-fitting component;

a restriction portion having a restriction surface configured to come into contact with the press-fitting target component; and

15 a position setting mechanism which sets a pressing position of the pressing surface of the pressing portion in the press-fitting direction and a restriction position of the restriction surface of the restriction portion in the press-fitting direction according to the press-fitting component and the press-fitting target component.

2. The press-fitting device according to claim 1, wherein:

20 the position setting mechanism has a press-fitting jig in which plural restriction portions are arranged at a prescribed interval and which is provided so as to be configured to move in an arrangement direction of the plural restriction portions; and

the press-fitting jig comprises:

25 an arrangement portion in which the plural restriction portions are arranged at the prescribed interval; and

a main body which is provided with the arrangement portion and is supported so as to be movable with respect to the pressing portion.

3. The press-fitting device according to claim 2, wherein:

30 the arrangement portion is provided with mounting portions on which the plural restriction portions are mounted respectively; and

each of the plural restriction portions has an engagement portion configured to be engaged with an associated mounting portion.

4. The press-fitting device according to claim 3, wherein:

the main body is supported rotatably to the press-fitting tool; and

the arrangement portion has plural flat surfaces that are arranged at a prescribed interval in a circumferential direction around a rotation axis of the main body and extend parallel with the rotation axis of the main body respectively, and the plural flat surfaces are provided with the plural mounting portions respectively.

5. The press-fitting device according to claim 3, wherein the press-fitting device includes a rotation mechanism which places the restriction surface of a desired one of the plural restriction portions at such position as to come into contact with the press-fitting target component by rotating the press-fitting jig about a rotation axis of the main body.

6. The press-fitting device according to claim 5, wherein the rotation mechanism includes:

a switching drive portion which is rotated by a switching drive source that is fixed to a frame on which the support portion is provided;

a switching shaft portion which supports the main body of the press-fitting jig and extends along the rotation axis of the press-fitting jig; and

a drive power transmission portion which transmits rotational power of the switching drive portion to the switching shaft portion.

7. The press-fitting device according to claim 4, wherein:

the pressing mechanism has a movable portion which is moved in the press-fitting direction in accordance with a press-fitting operation;

the press-fitting tool has a press-fitting movable body which is connected to and moves together with the movable portion; and

the press-fitting movable body includes:

a connection portion which is provided on one side in the press-fitting direction and is connected to the movable portion;

the pressing portion which is provided on the other side in the press-fitting direction; and

a guide portion which guides movement of the press-fitting jig in the press-fitting direction.

8. The press-fitting device according to claim 7, wherein:

the position setting mechanism has a jig support unit which is movable with respect to the press-fitting movable body; and

5 the jig support unit includes:

an elevation drive portion which moves the jig support unit with respect to the press-fitting movable body;

a jig support portion which supports the press-fitting jig rotatably; and

10 a guide engagement portion which is engaged with the guide portion and guides the jig support portion in the press-fitting direction with respect to the press-fitting movable body.

9. The press-fitting device according to claim 6, wherein the drive power transmission unit includes:

15 a first magnet body which is fixed to the switching drive portion, is provided with N poles and S poles alternately in a circumferential direction around a rotation axis of the switching drive portion, and is rotated by the switching drive source; and

a second magnet body which is fixed to the switching shaft portion, is provided with N poles and S poles alternately in a circumferential direction around a rotation axis of the
20 switching shaft portion, and is rotated by rotation of the first magnet body.

10. The press-fitting device according to claim 7, wherein:

the press-fitting jig has a switching shaft portion which extends along the rotation axis of the press-fitting jig;

25 the press-fitting movable body has a housing portion in which the press-fitting jig is disposed;

the housing portion has a rotation stop surface which restricts rotation of the press-fitting jig when a flat surface, provided with a restriction portion, of the arrangement portion of the press-fitting jig comes into contact with the rotation stop surface; and

30 the press-fitting movable body is formed with an insertion hole that enables movement of the switching shaft portion in the press-fitting direction.

11. The press-fitting device according to claim 6, wherein:

the pressing mechanism has a movable portion which is moved in the press-fitting direction in accordance with a press-fitting operation,

the press-fitting device further comprising:

a pressing drive source which moves the movable portion in the press-fitting direction
5 in accordance with the press-fitting operation; and

a frame including a pressing fixing portion to which the pressing drive source is fixed and a switching fixing member to which a switching drive source that rotates the switching shaft portion is fixed.

10 12. The press-fitting device according to claim 11, wherein:

the position setting mechanism has a discrimination body for discrimination between the plural restriction portions of the press-fitting jig;

the discrimination body has discrimination portions respectively corresponding to the restriction portions provided in the press-fitting jig; and

15 the press-fitting device further comprises a detection unit configured to detect each of the discrimination portions.

13. The press-fitting device according to any one of claims 1 to 12, further comprising:

a pressing control portion which controls the pressing mechanism, wherein:

20 the pressing control portion sets the pressing position and the restriction position so that the difference between the pressing position and the restriction position in the press-fitting direction becomes a proper value according to dimensions of the press-fitting component and the press-fitting target component; and

the pressing control portion performs a control of moving the pressing portion and
25 the restriction portion to the pressing position and restriction position set by the pressing control portion respectively.

14. A press-fitting jig used in a press-fitting device for press-fitting a press-fitting component with a press-fitting target component, wherein:

30 the press-fitting device comprises:

a support portion which supports the press-fitting target component; and

a pressing mechanism having a press-fitting tool configured to move in a press-fitting direction with respect to the support portion;

the press-fitting tool comprises:

a pressing portion having a pressing surface which presses the press-fitting component;

5 a restriction portion having a restriction surface configured to come into contact with the press-fitting target component; and

a position setting mechanism which sets a pressing position of the pressing surface of the pressing portion in the press-fitting direction and a restriction position of the restriction surface of the restriction portion in the press-fitting direction according to the press-fitting component and the press-fitting target component;

10 plural restriction portions are arranged in the press-fitting jig at a prescribed interval and the press-fitting jig is provided so as to be configured to move in an arrangement direction of the plural restriction portions; and

the press-fitting jig comprises:

15 an arrangement portion in which plural restriction portions are arranged at a prescribed interval;

a main body provided with the arrangement portion; and

a main body portion which is supported to the main body movably.

15. The press-fitting jig according to claim 14, wherein:

20 the arrangement portion is provided with mounting portions on which the plural restriction portions are mounted respectively; and

an engagement portion of each of the plural restriction portions is engaged with an associated mounting portion.

25 16. The press-fitting jig according to claim 15, wherein:

a hole that enables rotatable support of the main body by the press-fitting tool is formed through the main body; and

the arrangement portion has plural flat surfaces that are arranged at a prescribed interval in a circumferential direction around a rotation axis of the main body and extend 30 parallel with the rotation axis of the main body respectively, and the plural flat surfaces are provided with the plural mounting portions respectively.

17. The press-fitting jig according to any one of claims 14 to 16, wherein the plural

restriction portions include:

a reference restriction portion that makes the difference between the restriction position and the press-fitting position in the press-fitting direction equal to a reference length;

5 a first restriction portion that makes the difference between the restriction position and the press-fitting position in the press-fitting direction shorter than the reference length; and

a second restriction portion that makes the difference between the restriction position and the press-fitting position in the press-fitting direction longer than the reference length.

18. A manufacturing device for manufacturing a press-fit product in which a press-fitting
10 component is fitted with the press-fitting target component, comprising:

a first measuring portion which measures a dimension of the press-fitting target component;

a second measuring portion which measures a dimension of the press-fitting component; and

15 a press-fitting portion which press-fits the press-fitting component with the press-fitting target component, wherein:

the press-fitting portion comprises a press-fitting device which performs press-fitting based on the dimension of the press-fitting target component and the dimension of the press-fitting component;

20 the press-fitting device comprises:

a support portion which supports the press-fitting target component; and

a pressing mechanism having a press-fitting tool configured to move in a press-fitting direction with respect to the support portion; and

the press-fitting tool comprises:

25 a pressing portion having a pressing surface which presses the press-fitting component;

a restriction portion having a restriction surface configured to come into contact with the press-fitting target component; and

30 a position setting mechanism which sets a pressing position of the pressing surface of the pressing portion in the press-fitting direction and a restriction position of the restriction surface of the restriction portion in the press-fitting direction according to the press-fitting component and the press-fitting target component.

19. The manufacturing device according to claim 18, further comprising:
a control portion which controls the press-fitting tool, wherein;
the control portion includes:

a first recording portion which records a first dimension of the press-fitting
5 target component measured by the first measuring portion;

a second recording portion which records a second dimension of the press-
fitting component measured by the second measuring portion; and

a reference information setting portion in which a reference interval
dimension is set, the reference interval dimension being a preset press-fitting position of the
10 press-fitting component with respect to the press-fitting target component.

20. The manufacturing device according to claim 18, further comprising:

a tentative press-fitting portion which press-fits the press-fitting component with the
press-fitting target component to a tentative position in the press-fitting target component in the
15 press-fitting direction by moving the press-fitting component with respect to the press-fitting
target component.

21. The manufacturing device according to any one of claims 18 to 20, further
comprising:

20 a product measuring portion which measures a press-fitting position of the press-
fitting component in the press-fit product in which the press-fitting component is fitted with the
press-fitting target component.
