New peptide derivatives

This invention relates to new competitive inhibitors of trypsin-like serine proteases, especially thrombin and kininogenases such as kallikrein, their synthesis, pharmaceutical compositions containing the compounds as active ingredients, and the use of the compounds as thrombin inhibitors and anticoagulants and as antiinflammatory inhibitors, respectively.
The invention also relates to novel use of compounds as starting materials in synthesis of a serine protease inhibitor. Furthermore the invention relates to a novel structural fragments in serine protease inhibitors.

BACKGROUND

Blood coagulation is the key process involved in both haemostasis (i.e. prevention of blood loss from a damaged vessel) and thrombosis (i.e. the pathological occlusion of a blood vessel by a blood clot). Coagulation is the result of a complex series of enzymatic reactions, where one of the final steps is conversion of the proenzyme prothrombin to the active enzyme thrombin.

Thrombin plays a central role in coagulation. It activates platelets, it converts fibrinogen into fibrin monomers, which polymerise spontaneously into filaments, and it activates factor XIII, which in turn crosslinks the polymer to insoluble fibrin. Thrombin further activates factor V and factor VIII in a positive feedback reaction. Inhibitors of thrombin are therefore expected to be effective anticoagulants by inhibition of platelets, fibrin formation and fibrin stabilization. By inhibiting the positive feedback

mechanism they are expected to excert inhibition early in the chain of events leading to coagulation and thrombosis.

Kininogenases are serine proteases that act on kininogens to produce kinins (bradykinin, kallidin, and Met-Lys-bradykinin). Plasma kallikrein, tissue kallikrein, and mast cell tryptase represent important kininogenases.

Kinins (bradykinin, kallidin) are generally involved in inflammation. For example, the active inflammation process is associated with increased permeability of the blood vessels resulting in extravasation of plasma into the tissue. The ensuing plasma exudate contains all the protein systems of circulating blood. The plasma-derived kininogens inevitably will be interacting with different kallikreins, forming kinins continually as long as the active plasma exudation process is ongoing. Plasma exudation occurs independent of the mechanisms that are involved in the inflammation, whether it is allergy, infection or other factors (Persson et al., Editorial, Thorax, 1992, 47:993-1000). Plasma exudation is thus a feature of many diseases including asthma, rhinitis, common cold, and inflammatory bowel diseases. Particulary in allergy mast cell tryptase will be released (Salomonsson et al., Am. Rev. Respir. Dis., 1992, 146:1535-1542) to contribute to kinin formation and other pathogenic events in asthma, rhinitis, and intestinal diseases.

The kinins are biologically highly active substances with smooth muscle effects, sectretory effects, neurogenic effects, and actions that may perpetuate inflammatory processes including activation of phospholipase A_2 and increasing vascular permeability. The latter action potentially induces a vicious circle

with kinins providing for the generation of more kinins etc.

Tissue kallikrein cleaves primarily low molecular weight kininogen to produce kallidin and plasma kallikrein preferably releases bradykinin from high molecular weight kininogen.

PRIOR ART

Inhibitors of thrombin based on the amino acid sequence around the cleavage site for the fibrinogen Aα chain were first reported by Blombäck et al. in J. Clin. Lab. Invest. 24, suppl 107, 59, (1969), who suggested the sequence Phe-Val-Arg (P9-P2-P1, herein referred to as the P3-P2-P1 sequence) to be the best inhibitor.

In US 4,346,078 has S. Bajusz et al. described the thrombin inhibitor H-DPhe-Pro-Agm, a dipeptidyl derivative with an aminoalkyl guanidine in the P1-position.

Inhibitors of thrombin based on peptide derivatives with a cyclic aminoalkyl guanidine, e.g. 3-aminomethyl-1-amidinopiperidine, in the P1-position have been disclosed in EP-A2-0,468,231.

In EP-A2-0,185,390 has S. Bajusz et. al. disclosed that replacing the agmatine with an arginine aldehyde gave a thrombin inhibitor which had much higher potency.

Inhibitors of kallikrein based on the amino acid sequence around the cleavage site Arg-Ser have been reported earlier.

The arginine chloromethyl ketones H-DPro-Phe-Arg-CH_2Cl

and H-D Phe-Phe-Arg-CH_2Cl were reported as plasma kallikrein inhibitors by Kettner and Shaw in Biochemistry 1978, 17:4778-4784 and Meth. Enzym. 1981, 80:826-842.

Likewise, esters and amides containing the H-DPro-Phe-Arg sequence were reported by Fareed et al. in Ann. N.Y. Acad. Sci. 1981, 370:765-784 to be plasma kallikrein inhibitors.

Inhibitors of serine proteases that are based on electrophilic ketones instead of aldehydes in the P1-position are described in the following patent documents:

EP-A2-0,195,212 describing peptidyl α-keto esters and amides, EP-A1-0,362,002 describing fluoroalkylamide ketones and EP-A2-0,364,344 describing α,β,δ- triketo compounds possessing different peptidase inhibiting properties.

Inhibitors of trypsin-like serine proteases, such as thrombin and kallikrein, based on C-terminal boronic acid derivatives of arginine and isothiouronium analogues thereof have been revealed in EP-A2-0,293,881.

WO 92/04371 describing kininogenase inhibitors, e.g. kallikrein inhibitors based on derivatives of arginine.

EP-A1-0,530,167 describing α-alkoxy ketone derivatives of arginine as thrombin inhibitors.

DISCLOSURE OF THE INVENTION

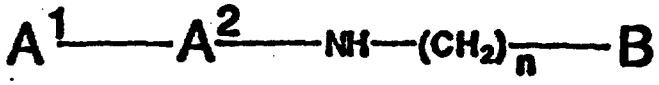

An object of the present invention is to provide novel

and potent trypsine-like serine protease inhibitors, especially anticoagulantia and antiinflammatory compounds with competitive inhibitory activity towards their enzyme i.e. causing reversible inhibition. More specifically anticoagulants for prophylaxis and treatment of thromboembolic diseases such as venous thrombosis, pulmonary embolism, arterial thrombosis, in particular myocardial infarction and cerebral thrombosis, general hypercoagulable states and local hypercoagulable states, e.g. following angioplasty and coronary bypass operations, and other situations where thrombin is believed to play a role, e.g. Alzheimers disease, as well as inhibition of kininogenases for treatment of inflammatory disorders e.g. asthma, rhinitis, urticaria, inflammatory bowel disease, and arthritis. A further object is to obtain thrombin inhibitors which are orally bioavailable and selective in inhibiting thrombin over other serine proteases. A further object of the invention is to obtain kininogenase inhibitors which can be given orally, rectally, topically e.g. dermally, or via the inhalation route.

DETAILED DESCRIPTION OF THE INVENTION

The following description is illustrative of aspects of the invention.

EXPERIMENTAL PART

General experimental Procedures.

Mass spectra were recorded on a Finnigan MAT TSQ 700 triple quadropole mass spectrometer equipped with an electrospray interface.

The ^{1}H NMR and ^{13}C NMR measurements were performed on BRUKER AC-P 300 and BRUKER AM 500 spectrometers, the former operating at a ^{1}H frequency of 500.14 MHz and a ^{13}C frequency of 125.76 MHz and the latter at ^{1}H and ^{13}C frequency of 300.13 MHz and 75.46 MHz respectively.

The samples were about 10-50 mg dissolved in 0.6 ml of either of the following solvents ; $CDCl_3$ (isotopic purity > 99.8%), CD_3OD (isotopic purity > 99.95%), D_2O (isotopic purity > 99.98%) or DMSO-d_6 (isotopic purity > 99.8%). All solvents where purchased from Dr. Glaser AG, Basel.

The ^{1}H and ^{13}C chemical shift values in $CDCl_3$ and CD_3OD are relative to tetramethylsilane as an external standard. The ^{1}H chemical shifts in D_2O are relative to the sodium salt of 3-(trimethylsilyl)-d_4-propanoic acid and the ^{13}C chemical shifts in D_2O are referenced relative to 1,4-dioxane (67.3 ppm), both as external standard. Calibrating with an external standard may in some cases cause minor shift differences compared to an internal standard, however, the difference in ^{1}H chemical shift is less than 0.02 ppm and in ^{13}C less than 0.1 ppm.

The ^1H NMR spectrum of peptide sequences containing a proline or a "proline like" residue frequently exhibits two sets of resonances. This corresponds to the existence of two contributing conformers with respect to the rotation around the amide bond, where proline is the N-part of the amide bond. The conformers are named **cis** and **trans**. In our compounds the sequences (R)Cha-Aze-, (R)Cha-Pro- and (R)Cha-Pic- often give rise to a cis-trans equilibrium with one conformer as the preponderant conformer (>90%). In those cases only the ^1H chemical shifts of the major rotamer is reported. Only in the cases where the signals of the minor rotamer are clearly resolved they are reported in the NMR documentation. The same criterium is valid for the NH-signals in $CDCl_3$, only in the cases where the signals are clearly resolved they are reported in the NMR-documentation. This implies that the number of protons reported for some of the intermediates are less than the number of protons expected from the chemical formula.

Thin-Layer Chromatography was carried out on commercial Merck Silicagel $60F_{254}$ coated glass or aluminium plates. Visualisation was by a combination of UV-light, followed by spraying with a solution prepared by mixing 372 ml of EtOH(95%), 13.8 ml of concentrated H_2SO_4, 4.2 ml of concentrated acetic acid and 10.2 ml of p-methoxy benzaldehyde or phosphomolybdic acid reagent (5-10 w.t % in EtOH(95%)) and heating.

Flash chromatography was carried out on Merck Silica gel 60 (40-63 mm, 230-400 mesh) under pressure of air.

Reversed phase high-performance liquid chromatography (in the Examples referred to as RPLC) was performed on a Waters M-590 instrument equipped with three reverse phase Kromasil 100,C8 columns (Eka-Nobel) having

This Sheet Has Been Replaced

different dimensions for analytical (4.6 mm x 250 mm), semipreparative (1" x 250 mm) and preparative (2" x 500 mm) chromatography detecting at 226 nm.

Freeze-drying was done on a Leybold-Heraeus, model Lyovac GT 2, apparatus.

Preparation of starting materials

Boc-(R)Pgl-OH

Prepared in the same way as described for Boc-(R)Cha-OH (vide infra) from H-(R)Pgl-OH.

Boc-(R)Cha-OH

To a solution of H-(R)Cha-OH, 21.55 g (125.8 mmol), in 130 ml 1 M NaOH and 65 ml THF was added 30 g (137.5 mmol) of $(Boc)_2O$ and the mixture was stirred for 4.5 h at room temperature. The THF was evaporated and an additional 150 ml of water was added. The alkaline aqueous phase was washed twice with EtOAc, then acidified with 2 M $KHSO_4$ and extracted with 3 x 150 ml of EtOAc. The combined organic phase was washed with water, brine and dried (Na_2SO_4). Evaporation of the solvent afforded 30.9 g (90.5 %) of the title compound as a white solid.

Boc-(R)Hop-OH

^{1}H-NMR (300 MHz, $CDCl_3$): δ 1.45 (s, 9H), 2.00 (m, 1H), 2.22 (m, 1H), 2.75 (bt, 2H), 4.36 (bs, 1H), 5.05 (bs, 1H), 7.15-7.33 (m, 5H).

4-(tert-butyloxycarbonylaminomethyl) pyridine

To a solution of 10.81 g (100 mmol) 4-aminomethyl pyridine in 100 ml THF was added 24 g (110 mmol) Boc_2O dissolved in 70 ml THF at 10°C for 20 minutes. The solution was allowed to reach room temperature and stirred for 4 h (a precipitate was formed during the reaction and the slurry became red).The solvent was removed and the residue was dissolved in EtOAc and filtered through silica gel. Evaporation of the solvent gave the title compound as a red oil which crystallized on standing. The crude product was used without further purification.

^{1}H-NMR (300 MHz, $CDCl_3$): δ 1.45 (s, 9H), 4.32 (d, 2H), 5.05 (bs, 1H (NH)), 7.2 (d, 2H), 8.55 (d, 2H).

A solution of 20.23 g (0.31 mol) sodium azide in 50 ml water was added to 49.15 g (251 mmol) 4-cyanobenzyl bromide in 200 ml DMF at ambient temperature. An exothermic reaction took place and after 1.5 h the reaction mixture was diluted with 200 ml toluene(**caution:** In order to avoid separation of potentially explosive azide compounds it is adviceable to add the toluene to the rection mixture before addition of the water) and 500 ml water. The aqueous phase was extracted with an additional 2x50 ml toluene. The combined organic extracts were washed with 2x50 ml water and brine and finally dried ($MgSO_4$) and filtered. The solution was used as such in the next step.

After 48 h most of the solvent was removed and 200 ml 3.75 M NaOH solution was added whereupon 4-amidino benzyl azide precipitated as colourless crystals. The crystals were isolated by filtration. At this point the yield of 4-amidino benzyl azide was 22.5 g (total 51%).

Biology

Determination of Thrombin clotting Time (TT):

Human thrombin (T 6769, Sigma Chem Co) in buffer solution, pH 7.4, 100 μl, and inhibitor solution, 100 μl, were incubated for one min. Pooled normal citrated human plasma, 100 μl, was then added and the clotting time measured in an automatic device (KC 10, Amelung).

The clotting time in seconds was plotted against the inhibitor concentration, and the IC_{50}TT was determined

This Sheet Has Been Replaced

by interpolation.

$IC_{50}TT$ is the concentration of inhibitor that doubles the thrombin clotting time for human plasma.

Determination of Activated Partial Thromboplastin Time (APTT)

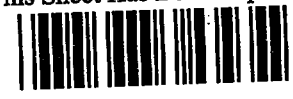

APTT was determined in pooled normal human citrated plasma with the reagent PTT Automated 5 manufactured by Stago. The inhibitors were added to the plasma (10 µl inhibitor solution to 90 µl plasma) and APTT was determined in the mixture by use of the coagulation analyser KC10 (Amelung) according to the instructions of the reagent producer. The clotting time in seconds was plotted against the inhibitor concentration in plasma and the $IC_{50}APTT$ was determined by interpolation.

$IC_{50}APTT$ is defined as the concentration of inhibitor in plasma that doubled the Activated Partial Thromboplastin Time.

Determination of thrombin time ex vivo

The inhibition of thrombin after oral administration of the compounds were examined in conscious rats that two days prior to the experiment were equipped with a catheter for blood sampling from the carotid artery. On the experimental day blood samples were withdrawn at fixed times after the administration of the compound into plastic tubes containing 1 part sodium citrate solution (0.13 mol per L.) and 9 parts of blood. The tubes were centrifuged to obtain platelet poor plasma. The plasma was used for determination of thrombin time as described below.

This Sheet Has Been Replaced

The citrated rat plasma, 100 µl, was diluted with a saline solution, 0.9%, 100 µl, and plasma coagulation was started by the addition of human thrombin (T 6769, Sigma Chem Co, USA) in a buffer solution, pH 7.4, 100 µl. The clotting time was measured in an automatic device (KC 10, Amelumg, Germany).

Determinaton of the inhibition constant K_i for plasma kallikrein

K_i determinations were made with a chromogenic substrate method, and performed on a Cobas Bio centrifugal analyzer manufactured by Roche (Basel, Switzerland). Residual enzyme activity after incubation of human plasma kallikrein with various concentrations of test compound was determined at three different substrate concentrations, and measured as change in optical absorbance at 405 nm and 37°C.

Human plasma kallikrein (E.C.3.4.21.34, Chromogenix AB, Mölndal, Sweden), 250 µl of 0.4 nkat/ml in buffer (0.05 mol/l Tris-HCl, pH 7.4, l 0.15 adjusted with NaCl) with bovine albumin 5 g/l (cat no 810033, ICI Biochemicals Ltd, High Wycombe, Bucks, GB), was incubated for 300 s with 80 µl of test compound solution in 0.15 mol/l NaCl containing albumin 10 g/l. An additional 10 µl of water was supplied in this step. Then 40 µl of kallikrein substrate (S-2302, Chromogenix AB, 1.25, 2.0 or 4.0 mmol/l in water) was added together with another 20 µl of water, and the absorbance change monitored.

K_i was evaluated from Dixon plots, i.e. diagrams of inhibitor concentration versus 1/ (ΔA/min), where the data for the different substrate concentrations form straight lines which intercept at $x = -K_i$.

New peptide derivatives

This invention relates to new competitive inhibitors of trypsin-like serine proteases, especially thrombin and kininogenases such as kallikrein, their synthesis, pharmaceutical compositions containing the compounds as active ingredients, and the use of the compounds as thrombin inhibitors and anticoagulants and as antiinflammatory inhibitors, respectively.
The invention also relates to novel use of compounds as starting materials in synthesis of a serine protease inhibitor. Furthermore the invention relates to a novel structural fragments in serine protease inhibitors.

BACKGROUND

Blood coagulation is the key process involved in both haemostasis (i.e. prevention of blood loss from a damaged vessel) and thrombosis (i.e. the pathological occlusion of a blood vessel by a blood clot). Coagulation is the result of a complex series of enzymatic reactions, where one of the final steps is conversion of the proenzyme prothrombin to the active enzyme thrombin.

Thrombin plays a central role in coagulation. It activates platelets, it converts fibrinogen into fibrin monomers, which polymerise spontaneously into filaments, and it activates factor XIII, which in turn crosslinks the polymer to insoluble fibrin. Thrombin further activates factor V and factor VIII in a positive feedback reaction. Inhibitors of thrombin are therefore expected to be effective anticoagulants by inhibition of platelets, fibrin formation and fibrin stabilization. By inhibiting the positive feedback

mechanism they are expected to excert inhibition early in the chain of events leading to coagulation and thrombosis.

Kininogenases are serine proteases that act on kininogens to produce kinins (bradykinin, kallidin, and Met-Lys-bradykinin). Plasma kallikrein, tissue kallikrein, and mast cell tryptase represent important kininogenases.

Kinins (bradykinin, kallidin) are generally involved in inflammation. For example, the active inflammation process is associated with increased permeability of the blood vessels resulting in extravasation of plasma into the tissue. The ensuing plasma exudate contains all the protein systems of circulating blood. The plasma-derived kininogens inevitably will be interacting with different kallikreins, forming kinins continually as long as the active plasma exudation process is ongoing. Plasma exudation occurs independent of the mechanisms that are involved in the inflammation, whether it is allergy, infection or other factors (Persson et al., Editorial, Thorax, 1992, 47:993-1000). Plasma exudation is thus a feature of many diseases including asthma, rhinitis, common cold, and inflammatory bowel diseases. Particulary in allergy mast cell tryptase will be released (Salomonsson et al., Am. Rev. Respir. Dis., 1992, 146:1535-1542) to contribute to kinin formation and other pathogenic events in asthma, rhinitis, and intestinal diseases.

The kinins are biologically highly active substances with smooth muscle effects, sectretory effects, neurogenic effects, and actions that may perpetuate inflammatory processes including activation of phospholipase A_2 and increasing vascular permeability. The latter action potentially induces a vicious circle

with kinins providing for the generation of more kinins etc.

Tissue kallikrein cleaves primarily low molecular weight kininogen to produce kallidin and plasma kallikrein preferably releases bradykinin from high molecular weight kininogen.

PRIOR ART

Inhibitors of thrombin based on the amino acid sequence around the cleavage site for the fibrinogen Aα chain were first reported by Blombäck et al. in J. Clin. Lab. Invest. 24, suppl 107, 59, (1969), who suggested the sequence Phe-Val-Arg (P9-P2-P1, herein referred to as the P3-P2-P1 sequence) to be the best inhibitor.

In US 4,346,078 has S. Bajusz et al. described the thrombin inhibitor H-DPhe-Pro-Agm, a dipeptidyl derivative with an aminoalkyl guanidine in the P1-position.

Inhibitors of thrombin based on peptide derivatives with a cyclic aminoalkyl guanidine, e.g. 3-aminomethyl-1-amidinopiperidine, in the P1-position have been disclosed in EP-A2-0,468,231.

In EP-A2-0,185,390 has S. Bajusz et. al. disclosed that replacing the agmatine with an arginine aldehyde gave a thrombin inhibitor which had much higher potency.

Inhibitors of kallikrein based on the amino acid sequence around the cleavage site Arg-Ser have been reported earlier.

The arginine chloromethyl ketones H-DPro-Phe-Arg-CH_2Cl

and H-D Phe-Phe-Arg-CH_2Cl were reported as plasma kallikrein inhibitors by Kettner and Shaw in Biochemistry 1978, 17:4778-4784 and Meth. Enzym. 1981, 80:826-842.

Likewise, esters and amides containing the H-DPro-Phe-Arg sequence were reported by Fareed et al. in Ann. N.Y. Acad. Sci. 1981, 370:765-784 to be plasma kallikrein inhibitors.

Inhibitors of serine proteases that are based on electrophilic ketones instead of aldehydes in the P1-position are described in the following patent documents:

EP-A2-0,195,212 describing peptidyl α-keto esters and amides, EP-A1-0,362,002 describing fluoroalkylamide ketones and EP-A2-0,364,344 describing α,β,δ- triketo compounds possessing different peptidase inhibiting properties.

Inhibitors of trypsin-like serine proteases, such as thrombin and kallikrein, based on C-terminal boronic acid derivatives of arginine and isothiouronium analogues thereof have been revealed in EP-A2-0,293,881.

WO 92/04371 describing kininogenase inhibitors, e.g. kallikrein inhibitors based on derivatives of arginine.

EP-A1-0,530,167 describing α-alkoxy ketone derivatives of arginine as thrombin inhibitors.

DISCLOSURE OF THE INVENTION

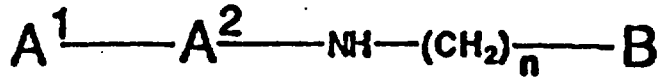

An object of the present invention is to provide novel

and potent trypsine-like serine protease inhibitors, especially anticoagulantia and antiinflammatory compounds with competitive inhibitory activity towards their enzyme i.e. causing reversible inhibition. More specifically anticoagulants for prophylaxis and treatment of thromboembolic diseases such as venous thrombosis, pulmonary embolism, arterial thrombosis, in particular myocardial infarction and cerebral thrombosis, general hypercoagulable states and local hypercoagulable states, e.g. following angioplasty and coronary bypass operations, and other situations where thrombin is believed to play a role, e.g. Alzheimers disease, as well as inhibition of kininogenases for treatment of inflammatory disorders e.g. asthma, rhinitis, urticaria, inflammatory bowel disease, and arthritis. A further object is to obtain thrombin inhibitors which are orally bioavailable and selective in inhibiting thrombin over other serine proteases. A further object of the invention is to obtain kininogenase inhibitors which can be given orally, rectally, topically e.g. dermally, or via the inhalation route.

Medical and pharmaceutical use

The invention also provides compositions and methods for the treatment, in a human or animal organism, of conditions where inhibition of thrombin is required and of physiologically disorders especially inflammatory diseases.

The thrombin inhibiting compounds of the invention are expected to be useful in particular in animals including man in treatment or prophylaxis of thrombosis and hypercoagulability in blood and tissues. They are furthermore expected to be useful in situations where there is an undesirable excess of the thrombin without signs of hypercoagulability, for example as in Alzheimers disease and pancreatitis. Disease states in which these compounds have a potential utility, in treatment and/or prophylaxis, include venous thrombosis

and pulmonary embolism, arterial thrombosis, such as in myocardial infarction, unstable angina, thrombosis-based stroke and peripheral arterial thrombosis and systemic embolism usually from the atrium during arterial fibrillation or from the left ventricule after transmural myocardial infarction. Further, these compounds have expected utility in prophylaxis of atherosclerotic diseases such as coronary arterial disease, cerebral arterial disease and peripheral arterial disease. Further, these compounds are expected to have synergistic antithrombotic effects when combined with any antithrombotic agent with a different mechanism of action, such as the antiplatelet agent acetylsalicylic acid. Further, these compounds are expected to be useful together with thrombolytics in thrombotic diseases, in particular myocardial infarction. Further, these compounds have expected utility in prophylaxis for re-occlusion after thrombolysis, percutaneous trans-luminal angioplasty (PTCA) and coronary bypass operations. Further, these compounds have expected utility in treatment and prophylaxis of disseminated intravascular coagulation caused by bacteria, multiple trauma, intoxication or any other mechanism. Further, these compounds are expected to be useful in anticoagulant treatment when blood is in contact with foreign surfaces in the body such as vascular grafts, vasculars stemts, vascular catheters, mechanical and biological prosthetic or any other medical device. Further, these compounds have expected utility in anticoagulant treatment when blood is in contact with medical devices outside the body such as during cardiovascular surgery using or heart-lung machine or in haemodialysis.

DETAILED DESCRIPTION OF THE INVENTION

The following description is illustrative of aspects of the invention.

EXPERIMENTAL PART

General experimental Procedures.

Mass spectra were recorded on a Finnigan MAT TSQ 700 triple quadropole mass spectrometer equipped with an electrospray interface.

The ^{1}H NMR and ^{13}C NMR measurements were performed on BRUKER AC-P 300 and BRUKER AM 500 spectrometers, the former operating at a ^{1}H frequency of 500.14 MHz and a ^{13}C frequency of 125.76 MHz and the latter at ^{1}H and ^{13}C frequency of 300.13 MHz and 75.46 MHz respectively.

The samples were about 10-50 mg dissolved in 0.6 ml of either of the following solvents ; $CDCl_3$ (isotopic purity > 99.8%), CD_3OD (isotopic purity > 99.95%), D_2O (isotopic purity > 99.98%) or DMSO-d_6 (isotopic purity > 99.8%). All solvents where purchased from Dr. Glaser AG, Basel.

The ^{1}H and ^{13}C chemical shift values in $CDCl_3$ and CD_3OD are relative to tetramethylsilane as an external standard. The ^{1}H chemical shifts in D_2O are relative to the sodium salt of 3-(trimethylsilyl)-d_4-propanoic acid and the ^{13}C chemical shifts in D_2O are referenced relative to 1,4-dioxane (67.3 ppm), both as external standard. Calibrating with an external standard may in some cases cause minor shift differences compared to an internal standard, however, the difference in ^{1}H chemical shift is less than 0.02 ppm and in ^{13}C less than 0.1 ppm.

The ^1H NMR spectrum of peptide sequences containing a proline or a "proline like" residue frequently exhibits two sets of resonances. This corresponds to the existence of two contributing conformers with respect to the rotation around the amide bond, where proline is the N-part of the amide bond. The conformers are named **cis** and **trans**. In our compounds the sequences (R)Cha-Aze-, (R)Cha-Pro- and (R)Cha-Pic- often give rise to a cis-trans equilibrium with one conformer as the preponderant conformer (>90%). In those cases only the ^1H chemical shifts of the major rotamer is reported. Only in the cases where the signals of the minor rotamer are clearly resolved they are reported in the NMR documentation. The same criterium is valid for the NH-signals in $CDCl_3$, only in the cases where the signals are clearly resolved they are reported in the NMR-documentation. This implies that the number of protons reported for some of the intermediates are less than the number of protons expected from the chemical formula.

Thin-Layer Chromatography was carried out on commercial Merck Silicagel $60F_{254}$ coated glass or aluminium plates. Visualisation was by a combination of UV-light, followed by spraying with a solution prepared by mixing 372 ml of EtOH(95%), 13.8 ml of concentrated H_2SO_4, 4.2 ml of concentrated acetic acid and 10.2 ml of p-methoxy benzaldehyde or phosphomolybdic acid reagent (5-10 w.t % in EtOH(95%)) and heating.

Flash chromatography was carried out on Merck Silica gel 60 (40-63 mm, 230-400 mesh) under pressure of air.

Reversed phase high-performance liquid chromatography (in the Examples referred to as RPLC) was performed on a Waters M-590 instrument equipped with three reverse phase Kromasil 100,C8 columns (Eka-Nobel) having

different dimensions for analytical (4.6 mm x 250 mm), semipreparative (1" x 250 mm) and preparative (2" x 500 mm) chromatography detecting at 226 nm.

Boc-(R)Cha-OH

To a solution of H-(R)Cha-OH, 21.55 g (125.8 mmol), in 130 ml 1 M NaOH and 65 ml THF was added 30 g (137.5 mmol) of $(Boc)_2O$ and the mixture was stirred for 4.5 h at room temperature. The THF was evaporated and an additional 150 ml of water was added. The alkaline aqueous phase was washed twice with EtOAc, then acidified with 2 M $KHSO_4$ and extracted with 3 x 150 ml of EtOAc. The combined organic phase was washed with water, brine and dried (Na_2SO_4). Evaporation of the solvent afforded 30.9 g (90.5 %) of the title compound as a white solid.

To a solution of 17.7 g 4-tert-butyloxycarbonylaminomethyl pyridine in 125 ml MeOH was added 2 g of 5 % Rh/Al_2O_3 and the mixture was hydrogenated at 0.34 MPa over night. ^{1}H-NMR showed that the hydrogenation was incomplete. Therefore, the catalyst was filtered off and the solvent removed in vaccuo and the residue was dissolved in 100 ml acetic acid, 2 g of 5 % Rh/Al_2O_3 was added and the mixture was hydrogenated for 4 days at 0.34 MPa. The catalyst was filtered off and most of the acetic acid was removed in vaccuo. After addition of 50 ml water to the residue the mixture was made alkaline with 5 M NaOH and the water phase was extracted with 1 x 200 + 1 x 100 ml CH_2Cl_2. The combined organic phase was washed with 25 ml water and dried ($MgSO_4$). Evaporation of the solvent gave a 17.2 g of a brownish oil which was dissolved in 50 ml of diethyl ether. Addition of 200 ml pentane gave a precipitate which was filtered off to give 7.7 g of a brown powder. Evaporation of the mother liqour gave 7 g of a white oil. The brown powder was dissolved in 100 ml EtOAc and the organic phase was washed with 1 x 50 ml + 1 x 25 ml 1 M $KHSO_4$. 1-4 are mixed and an aqueous solution of 5 is added. The mixture is dried and milled and 6 is admixed. The mix is then compressed in a tablet machine.

Example B6

Inhaler powder

The active compound is micronized in a jet mill to a particle size suitable for inhalation (mass diameter < 4μm).

100 mg of the micronized powder is filled into a powder multidose inhaler (Turbohaler®). The inhaler is equipped with a dosing unit which delivers a dose of 1 mg.

Biology

Determination of Thrombin clotting Time (TT):

Human thrombin (T 6769, Sigma Chem Co) in buffer solution, pH 7.4, 100 μl, and inhibitor solution, 100 μl, were incubated for one min. Pooled normal citrated human plasma, 100 μl, was then added and the clotting time measured in an automatic device (KC 10, Amelung).

The clotting time in seconds was plotted against the inhibitor concentration, and the $IC_{50}TT$ was determined

This is the replacement sheet

Date: 6 MAR 1997

by interpolation.

$IC_{50}TT$ is the concentration of inhibitor that doubles the thrombin clotting time for human plasma.

Determination of Activated Partial Thromboplastin Time (APTT)

APTT was determined in pooled normal human citrated plasma with the reagent PTT Automated 5 manufactured by Stago. The inhibitors were added to the plasma (10 µl inhibitor solution to 90 µl plasma) and APTT was determined in the mixture by use of the coagulation analyser KC10 (Amelung) according to the instructions of the reagent producer. The clotting time in seconds was plotted against the inhibitor concentration in plasma and the $IC_{50}APTT$ was determined by interpolation.

$IC_{50}APTT$ is defined as the concentration of inhibitor in plasma that doubled the Activated Partial Thromboplastin Time.

Determination of thrombin time ex vivo

The inhibition of thrombin after oral administration of the compounds were examined in conscious rats that two days prior to the experiment were equipped with a catheter for blood sampling from the carotid artery. On the experimental day blood samples were withdrawn at fixed times after the administration of the compound into plastic tubes containing 1 part sodium citrate solution (0.13 mol per L.) and 9 parts of blood. The tubes were centrifuged to obtain platelet poor plasma. The plasma was used for determination of thrombin time as described below.

The citrated rat plasma, 100 µl, was diluted with a saline solution, 0.9%, 100 µl, and plasma coagulation was started by the addition of human thrombin (T 6769, Sigma Chem Co, USA) in a buffer solution, pH 7.4, 100 µl. The clotting time was measured in an automatic device (KC 10, Amelumg, Germany).

Determinaton of the inhibition constant K_i for plasma kallikrein

K_i determinations were made with a chromogenic substrate method, and performed on a Cobas Bio centrifugal analyzer manufactured by Roche (Basel, Switzerland). Residual enzyme activity after incubation of human plasma kallikrein with various concentrations of test compound was determined at three different substrate concentrations, and measured as change in optical absorbance at 405 nm and 37°C.

Human plasma kallikrein (E.C.3.4.21.34, Chromogenix AB, Mölndal, Sweden), 250 µl of 0.4 nkat/ml in buffer (0.05 mol/l Tris-HCl, pH 7.4, I 0.15 adjusted with NaCl) with bovine albumin 5 g/l (cat no 810033, ICI Biochemicals Ltd, High Wycombe, Bucks, GB), was incubated for 300 s with 80 µl of test compound solution in 0.15 mol/l NaCl containing albumin 10 g/l. An additional 10 µl of water was supplied in this step. Then 40 µl of kallikrein substrate (S-2302, Chromogenix AB, 1.25, 2.0 or 4.0 mmol/l in water) was added together with another 20 µl of water, and the absorbance change monitored.

K_i was evaluated from Dixon plots, i.e. diagrams of inhibitor concentration versus 1/ (ΔA/min), where the data for the different substrate concentrations form straight lines which intercept at $x = -K_i$.
