

FLOATING BODY TRANSISTOR CONSTRUCTIONS, SEMICONDUCTOR CONSTRUCTIONS, AND METHODS OF FORMING SEMICONDUCTOR CONSTRUCTIONS

TECHNICAL FIELD

[0001] *The invention pertains to semiconductor constructions and to methods of forming semiconductor constructions, and in particular aspects pertains to floating body transistor constructions and to methods of forming floating body transistor constructions.*

BACKGROUND OF THE INVENTION

[0002] There is a continuing goal to produce highly-integrated, high-speed, low-power memory devices. Traditional memory devices are static random access memory (SRAM) and dynamic random access memory (DRAM). SRAM can operate at high speeds, but typically consumes a relatively large amount of semiconductor real estate relative to other types of memory. DRAM traditionally comprises a transistor and a capacitor, and individual DRAM unit cells can be formed to consume relatively small amounts of semiconductor real estate as compared to SRAM cells. However, even DRAM is becoming too large for next generation levels of integration, because it is becoming increasingly difficult to create satisfactory capacitors with increasing levels of integration.

[0003] There is currently substantial interest in a new type of capacitor-less DRAM (also referred to as a floating body cell) that may be able to achieve much higher levels of integration than the traditional DRAM that utilized a capacitor. The new memory uses a floating body of a partially or fully depleted silicon on insulator (SOI) field effect transistor (FET) as a storage node, instead of using a storage capacitor.

[0004] It would be desirable to develop floating body cells which can be readily incorporated into semiconductor fabrication processes. It would also be desirable to develop memory arrays using floating body cells, and to develop methods for forming such arrays.

[0005] Although the methods and structures described herein were developed, at least in part, for integration of floating body cells; it is to be understood that the invention can have additional applications.

BRIEF DESCRIPTION OF THE DRAWINGS

[0006] Preferred embodiments of the invention are described below with reference to the following accompanying drawings.

[0007] Figs. 1-4 are a top view and cross-sectional side views of a fragment of a semiconductor construction at a preliminary processing stage of an exemplary aspect of the present invention. The cross-sections of Figs. 2, 3 and 4 are along the lines 2-2, 3-3 and 4-4, respectively, of Fig. 1. The cross-section of Fig. 4 is along lines 4-4 of Figs. 2 and 3; and the cross-sections of Figs. 2 and 3 are along the lines 2-2 and 3-3, respectively, of Fig. 4.

[0008] Figs. 5-8 are views of the fragments of Figs. 1-4, respectively, shown at a processing stage subsequent to that of Figs. 1-4. The cross-sections of Figs. 6, 7 and 8 are along the lines 6-6, 7-7 and 8-8, respectively, of Fig. 5. The cross-section of Fig. 8 is along lines 8-8 of Figs. 6 and 7; and the cross-sections of Figs. 6 and 7 are along the lines 6-6 and 7-7, respectively, of Fig. 8.

[0009] Figs. 9-12 are views of the fragments of Figs. 1-4, respectively, shown at a processing stage subsequent to that of Figs. 5-8. The cross-sections of Figs. 10, 11 and 12 are along the lines 10-10, 11-11 and 12-12, respectively, of Fig. 9. The cross-section of Fig. 12 is along lines 12-12 of Figs. 10 and 11; and the cross-sections of Figs. 10 and 11 are along the lines 10-10 and 11-11, respectively, of Fig. 12.

[0010] Figs. 13-17 are views of the semiconductor construction of Figs. 1-4 shown at a processing stage subsequent to that of Figs. 9-12. The fragments of Figs. 13-16 correspond to those of Figs. 1-4, respectively; and the fragment of Fig. 17 is an additional view besides those of Figs. 1-4. The cross-sections of Figs. 14, 15, 16 and 17 are along the lines 14-14, 15-15, 16-16 and 17-17, respectively, of Fig. 13. The cross-section of Figs. 16 and 17 are along lines 16-16 and 17-17, respectively, of Figs. 14 and 15; and the cross-sections of Figs. 14 and 15 are along the lines 14-14 and 15-15, respectively, of Figs. 16 and 17.

[0011] Figs. 18-21 are views of the fragments of Figs. 1-4, respectively, shown at a processing stage subsequent to that of Figs. 13-17. The cross-sections of Figs. 19, 20 and 21 are along the lines 19-19, 20-20 and 21-21, respectively, of Fig. 18. The cross-section of Fig. 21 is along lines 21-21 of Figs. 19 and 20; and the cross-sections of Figs. 19 and 20 are along the lines 19-19 and 20-20, respectively, of Fig. 21.

[0012] Figs. 22-25 are views of the fragments of Figs. 1-4, respectively, shown at a processing stage subsequent to that of Figs. 18-21. The cross-sections of Figs. 23, 24 and 25 are along the lines 23-23, 24-24 and 25-25, respectively, of Fig. 22. The cross-section of Fig. 25 is along lines 25-25 of Figs. 23 and 24; and the cross-sections of Figs. 23 and 24 are along the lines 23-23 and 24-24, respectively, of Fig. 25.

[0013] Figs. 26-29 are views of the fragments of Figs. 1-4, respectively, shown at a processing stage subsequent to that of Figs. 22-25. The cross-sections of Figs. 27, 28 and 29 are along the lines 27-27, 28-28 and 29-29, respectively, of Fig. 26. The cross-section of Fig. 29 is along lines 29-29 of Figs. 27 and 28; and the cross-sections of Figs. 27 and 28 are along the lines 27-27 and 28-28, respectively, of Fig. 29.

[0014] Figs. 30-33 are views of the fragments of Figs. 1-4, respectively, shown at a processing stage subsequent to that of Figs. 26-29. The cross-sections of Figs. 31, 32 and 33 are along the lines 31-31, 32-32 and 33-33, respectively, of Fig. 30. The cross-section of Fig. 33 is along lines 33-33 of Figs. 31 and 32; and the cross-sections of Figs. 31 and 32 are along the lines 31-31 and 32-32, respectively, of Fig. 33.

[0015] Figs. 34-37 are views of the fragments of Figs. 1-4, respectively, shown at a processing stage subsequent to that of Figs. 30-33. The cross-sections of Figs. 35, 36 and 37 are along the lines 35-35, 36-36 and 37-37, respectively, of Fig. 34. The cross-section of Fig. 37 is along lines 37-37 of Figs. 35 and 36; and the cross-sections of Figs. 35 and 36 are along the lines 35-35 and 36-36, respectively, of Fig. 37.

[0016] Fig. 38 is a three-dimensional view of a fragment of the semiconductor construction at the processing stage of Figs. 13-17.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0017] In particular aspects, the invention described herein pertains to a design for floating body transistor constructions in which source and drain lines are laid out along prongs of a U-shaped semiconductor fin. The layout can be reduced to $6F^2$ or smaller with current 90 nanometer technology when utilizing current pitch doubling procedures. Full feature $8F^2$ layouts may be manufacturable up to 40 nanometers and beyond. Structures formed in accordance with the present invention are expected to have high scalability, and good data retention.

[0018] Exemplary aspects of the invention are described with reference to Figs. 1-38.

[0019] Referring initially to Figs. 1-4, a semiconductor construction 10 is illustrated at a preliminary processing stage in accordance with an aspect of the present invention.

[0020] The construction 10 comprises a semiconductor base 12, an electrically insulative mass 14 (also referred to herein as an insulator 14) over the base, and semiconductor material 16 over the electrically insulative mass. The semiconductor material 16 and insulative material 14 can be considered to together be a semiconductor on insulator (SOI) construction.

[0021] Semiconductor base 12 can comprise any suitable semiconductor material, including, for example, bulk monocrystalline silicon of a silicon wafer. In some aspects, base 12 can be considered to be a semiconductor substrate. To aid in interpretation of the claims that follow, the terms "semiconductive substrate" and "semiconductor substrate" are defined to mean any construction comprising semiconductive material, including, but not limited to, bulk semiconductive materials such as a semiconductive wafer (either alone or in assemblies comprising other materials thereon), and semiconductive material layers (either alone or in assemblies comprising other materials). The term "substrate" refers to any supporting structure, including, but not limited to, the semiconductive substrates described above.

[0022] Although base 12 will typically comprise a semiconductor material, it is to be understood that the base can comprise other materials suitable for being supporting substrates in various aspects of the invention.

[0023] The electrically insulative material of mass 14 can comprise any suitable composition or combination of compositions, and in particular aspects will comprise, consist essentially of, or consist of silicon dioxide. Mass 14 can have a thickness of, for example, from about 1000Å to about 1500Å.

[0024] Semiconductor material 16 can comprise any suitable composition or combination of compositions, and in particular aspects will comprise, consist essentially of, or consist of silicon. Semiconductor material 16 will typically be monocrystalline, but it is to be understood that the material can be in any suitable form. In the shown aspect of the invention, material 16 is directly against insulator 14.

[0025] Construction 10 comprises a patterned mask 18 over material 16, with the mask being shown to comprise layers 20 and 22. Layer 20 can correspond to pad oxide (in other words, can consist essentially of, or consist of silicon dioxide), and layer 22 can consist essentially of, or consist of silicon nitride. Layer 20 can be buffered oxide thermally grown over material 16, and can have a thickness of, for example, from about 50Å to about 100Å. Layer 22 can have a thickness of from about 500Å to about 750Å.

[0026] The mask 18 has openings 24, 26 and 28 extending therethrough, and such openings also extend into semiconductor material 16. The formation of the openings through mask 18 and into material 16 can be accomplished with any suitable processing, including, for example: formation of a photolithographically patterned resist mask (not shown) over layer 22, transference of a pattern from the resist mask to underlying layers 20 and 22 with one or more suitable etches, further transference of the pattern into material 16 with suitable etching, and removal of the resist mask.

[0027] Semiconductor material 16 is shown to have a thickness 30, and the openings 24, 26 and 28 are shown to extend only partially into material 16, and accordingly not entirely through the thickness of the material. The thickness 30 can be, for example, from about 1500Å to about 2500Å, and the openings 24, 26 and 28 can extend to, for example, about three-fourths of the way through such thickness.

[0028] The openings 24, 26 and 28 can be seen to extend linearly in the top view of Fig. 1, and further to extend substantially parallel to one another. The linear directions that the openings 24, 26 and 28 extend along can be defined to be latitudinal directions 32. In some aspects, openings 24, 26 and 28 can be considered to be first trenches extending primarily linearly along the defined latitudinal directions.

[0029] Dashed boundaries 33, 35 and 37 are provided around trenches 24, 26 and 28, respectively. The dashed boundaries correspond to locations where troughs will ultimately be patterned from semiconductor material 16, as will become more clear from the discussion follows.

[0030] Referring next to Figs. 5-9, portions of materials 16, 20 and 22 are removed to form an opening 39, and leave separated structures 34, 36 and 38 along trenches 24, 26 and 28, respectively. Subsequently, opening 39 and trenches 24, 26 and 28 are filled with electrically insulative material 40. Electrically insulative material 40 can comprise any

suitable composition or combination of compositions, and in particular aspects can comprise, consist essentially of, or consist of silicon dioxide.

[0031] The opening 39 extends entirely through the thickness of semiconductor material 16, and in the shown aspect extends partially into the electrically insulative mass 14. The opening 39 can, for example, extend about halfway through the thickness of insulative mass 14. In some aspects, opening 39 will correspond to a plurality of openings, rather than to a single large opening.

[0032] As discussed previously, trenches 24, 26 and 28 can be referred to as first trenches to distinguish them from other trenches formed within construction 10. In some aspects, the formation of opening 39 can be considered formation of one or more second trenches which leave a plurality of spaced regions of semiconductor material 16 (specifically, semiconductor material of structures 34, 36 and 38) extending along and under the first trenches. The individual spaced regions of semiconductor material are trough-shaped, as can be seen in the cross-section of Fig. 8. Such trough-shaped regions contain sidewalls 41 along the opposing sides of the first trenches 24, 26 and 28, and contain central (or bottom) regions 43 under the first trenches. The trough-shaped structures are formed in the locations 33, 35 and 37 of Figs. 1-4.

[0033] In some aspects, the semiconductor material extending around first trenches 24, 26 and 28 can be considered to be U-shaped; with the sidewalls 41 being considered to be limbs or prongs of the U-shaped structures, and with the central regions 43 considered to be base or central portions of the U-shaped structures. In yet other alternative aspects, the sidewalls 41 can be considered to be upwardly-extending from central valley portions corresponding to regions 43.

[0034] The regions 34, 36 and 38 can be seen in Fig. 5 to have elongated segments 42 extending longitudinally along the trenches, and to have ends 44 connecting the elongated segments. The sidewalls of the troughs shown in Fig. 8 are along the elongated segments 42. However, it is noted that there are also sidewalls along the ends 44, as can be seen in Fig. 6.

[0035] The insulative material 40 fills the trenches 24, 26, and 28. Such trenches can be considered to be troughs of the trough-shaped regions 34, 36 and 38 of semiconductor

material 16; and thus insulative material 40 can be considered to fill the troughs (or alternatively valleys) of the trough-shaped regions of semiconductor material 16.

[0036] Insulative material 40 is shown to have a planarized upper surface 45. Such can be formed by initially providing material 40 to overfill trenches 24, 26 and 28, as well as opening 39; and to then subject material 40 to polishing to remove the material from over layer 22 and create the planarized upper surface 45. Suitable polishing can be chemical-mechanical polishing (CMP), and layer 22 can function as a stop during such polishing.

[0037] Opening 39 can be considered a deep opening, in that it is deeper than the trenches 24, 26 and 28. The formation of the opening 39 can be accomplished with any suitable processing, including, for example: formation of a photolithographically patterned resist mask (not shown) over layer 22 and trenches 24, 26 and 28; transference of a pattern from the resist mask to underlying layers 20 and 22 with one or more suitable etches; further transference of the pattern through material 16 and then partially into insulator 14, with suitable etching; and removal of the resist mask.

[0038] Although deep opening 39 is described as being formed after shallow trenches 24, 26 and 28 in the shown exemplary aspect of the invention, it is to be understood that the invention also encompasses aspects in which the order of formation of the deep opening and shallow trenches is reversed. Also, although the deep opening and shallow trenches are shown to be simultaneously filled with insulative material 40, it is to be understood that the insulative material could be provided within the shallow trenches prior to formation of the deep opening, or vice versa. Further, it is to be understood that the insulative material within the shallow trenches may be compositionally different than that within the deep opening in some aspects the invention.

[0039] Referring next to Figs. 9-12, trenches 50, 52, 54 and 56 are formed to extend through the trough-shaped semiconductor material structures of regions 34, 36 and 38. The trenches extend through masking materials 20 and 22, through semiconductor material 16, and partially into insulator 14. In particular aspects, the trenches 50, 52, 54 and 56 can extend to about halfway through the thickness of insulator 14. The formation of trenches 50, 52, 54 and 56 can be accomplished with any suitable processing, including, for example: formation of a photolithographically patterned resist mask (not shown) across construction 10 to define locations of the trenches; transference of a pattern from the resist

mask to underlying layers 20 and 22 with one or more suitable etches; further transference of the pattern through material 16 and then partially into insulator 14, with suitable etching; and removal of the resist mask.

[0040] The trenches 50, 52, 54 and 56 subdivide the trough-shaped structures into a plurality of trough-shaped slices sandwiched adjacent between pairs of the trenches. Individual trough-shaped slices subdivided from region 36 are labeled as slices 60, 62 and 64. Slice 62 is shown in Fig. 12 to comprise upwardly-projecting sidewalls 63 joining to a central bottom region 65. The cross-sections of Figs. 10 and 11 are through the bottom portion 65 and a sidewall 63, respectively. Trenches 50, 52, 54 and 56 can be referred to as a third trenches in some aspects of the invention to distinguish them from the first trenches 24, 26 and 28, and the second trench 39 (Figs 5-8).

[0041] The trenches 50, 52, 54 and 56 have peripheries comprising the various materials 14, 16, 20 and 22; as can be seen in the cross-sections of Figs. 10-12.

[0042] In the shown aspect of the invention, the trenches 50, 52, 54 and 56 extend primarily linearly along longitudinal directions 68 which are substantially orthogonal to the latitudinal directions 32. The term "substantially orthogonal" is used indicate that the longitudinal directions are orthogonal to the latitudinal directions within tolerances of fabrication and measurement, which can include but is not limited to applications in which the longitudinal directions are absolutely orthogonal to the latitudinal directions.

[0043] The trenches 52 and 56 join at an interconnecting region 70 which is peripheral to an array of the trough-shaped slices of semiconductor material 16. Interconnecting region 70 ultimately provides electrical interconnection between conductive materials formed within trenches 52 and 56, (specifically, back gates) as will become clear from the discussion follows. Interconnecting region 70 can also provide a widened pad suitable for electrical connection to other layers, as will become clear from the discussion follows. In some aspects, (not shown) trenches 52 and 56 are not interconnected. In such aspects, back gates ultimately formed within the trenches can be interconnected at another level besides that of the trenches 52 and 56; or at least some the back gates can be left unconnected to one another so that they can be separately biased and/or modulated.

[0044] Trenches 50 and 54 comprise widened regions 72 and 74 which can ultimately be utilized for patterning widened pads of conductive material suitable for electrical connection to other layers.

[0045] Referring next to Figs. 13-17, semiconductor material regions along the peripheries of the third trenches 50, 52, 54 and 56 are lined with one or more dielectric materials 76. In particular aspects, the one or more dielectric materials comprise, consist essentially of, or consist of silicon dioxide. If the dielectric material consists of silicon oxide, such can be referred to as gate oxide. The gate oxide can be formed by thermally growing the oxide from exposed regions of semiconductor material 16.

[0046] After the dielectric material 76 is formed, conductive gate material 78 is formed within the trenches 50, 52, 54 and 56. The conductive gate material can comprise any suitable composition or combination of compositions, and in particular aspects will comprise one or more metals. For instance, the conductive gate material can comprise, consist essentially of, or consist of one or more of titanium, ruthenium and titanium nitride. In the shown aspect of the invention, the conductive gate material 78 only partially fills the trenches 50, 52, 54 and 56, and specifically upper regions of the trenches are not filled by the conductive gate material. Such construction can be achieved by initially forming the conductive material to completely fill the trenches 50, 52, 54 and 56; and then recessing the conductive material within the trenches to leave the unfilled upper portions of the trenches. In particular aspects, the unfilled upper portions will be about 500 angstroms deep.

[0047] In the shown aspect the invention, electrically insulative caps are formed within the unfilled upper portions of the trenches over conductive material 78, with such caps comprising insulative materials 80 and 82. In some aspects, material 80 can comprise, consist essentially of, or consist of silicon dioxide; and material 82 can comprise, consist essentially of, or consist of silicon nitride. Also, it is to be understood that even though the caps are shown to comprise two different insulative materials, the invention includes other aspects (not shown) in which the caps comprise only one electrically insulative material, as well as aspects in which the caps comprise more than two electrically insulative materials.

[0048] The conductive material 78 within trenches 50, 52, 54 and 56 forms gatelines within each of the trenches. The gatelines can be considered to be planar gatelines, or in some aspects gate plates, in that the gatelines have relatively tall thin shapes as shown in

the cross-sections of Figs. 14, 15 and 17. The planar gates are spaced from semiconductor material 16 by the dielectric material 76.

[0049] In particular aspects, the planar gates can be considered to be alternating front gates and back gates, with the front gates being labeled 84 and 86, and the back gates being labeled 88 and 90. Notably, the back gates are electrically connected (in other words, electrically tied) to one another in the shown aspect through interconnect region 70. Thus, the back gates can be readily maintained at a common bias. As discussed previously, the invention can include other aspects in which the back gates are electrically tied through an interconnection at another level besides that of the gates, and yet other aspects in which at least some of the back gates are not electrically tied to one another.

[0050] In the shown aspect of the invention, the front gates and back gates are formed simultaneously with one another and accordingly have the same compositions as one another. It is to be understood, however, that the invention also includes aspects (not shown) in which the front gates and back gates differ in composition relative to one another. Also, although the shown aspect of the invention has the gate dielectric materials associated with the front gates being formed at the same time and of the same composition as the dielectric materials associated with the back gates (with all of such dielectric materials being indicated by the label 76), it is to be understood that the invention can also include aspects in which the dielectric materials associated with the back gates differ from those associated with the front gates.

[0051] The masking materials 20 and 22 (Figs. 9-12) have been removed at the processing stage of Figs. 13-17, and additional semiconductor material 92 has been formed over semiconductor material 16 in place of such masking materials. A dashed-line boundary is provided between semiconductor materials 16 and 92 to indicate an interface between such semiconductor materials, but it is to be understood that semiconductor materials 16 and 92 can be identical in composition to one another so that the materials merge to form a single material.

[0052] Masking materials 20 and 22 can be removed with any suitable etch, and in some aspects regions of construction 10 peripheral to materials 20 and 22 will be protected with a photoresist mask (not shown) during removal of material 20 and 22, and possibly also during formation of semiconductor material 92, and the photoresist mask will then be

removed. Materials 20 and 22 can be referred to as sacrificial materials, in that they are ultimately removed.

[0053] In some aspects, semiconductor material 16 consists of, or consists essentially of monocrystalline silicon; and semiconductor material 92 consists of, or consists essentially of monocrystalline silicon epitaxially grown from the monocrystalline silicon of semiconductor material 16. Thus, in some aspects semiconductor material 92 can be compositionally the same as semiconductor material 16.

[0054] The semiconductor material 92 is conductively doped to form source regions 94 alternating with drain regions 96. The conductive doping of material 92 can be accomplished with any suitable processing, including in situ doping and/or implant doping of the semiconductor material. The dopant can be either n-type or p-type.

[0055] The trough-shaped semiconductor slices of the processing stage of Figs. 13-17 can be considered to comprise upwardly-projecting sidewalls (or prongs) containing the combined semiconductor materials 16 and 92. The source/drain regions 94 and 96 are within such upwardly-projecting sidewalls. The source/drain regions can extend to any suitable depth into the sidewalls, including, for example, partially into material 92, entirely through material 92 to the interface with material 16, or entirely through material 92 and partially into material 16.

[0056] The cross-section of Fig. 16 shows that each trough-shaped semiconductor slice contains a source region 94 within one upwardly-projecting sidewall and a drain region 96 within the other upwardly-projecting sidewall.

[0057] The semiconductor material slices can be considered to be semiconductor material expanses adjacent the planar gates. In operation, the planar gates in combination with the semiconductor material expanses form floating body transistors. The source and drain within the prongs of a trough-shaped semiconductor expanse are gatedly connected to one another through a floating body contained within the central region of the semiconductor material 16 between the prongs. Such as illustrated in Fig. 38 which shows a three-dimensional view of a floating body transistor 100 comprising the semiconductor expanse 62 and the gatelines 86 and 88 on opposing sides of the expanse. The semiconductor materials 16 and 92 are shown in phantom view in Fig. 38 to indicate that such are behind various layers in the shown view. The gatelines 86 and 88 comprise the

conductive material 78 which is separated from semiconductor material 16 by dielectric materials 76 (not shown in Fig. 38). The trough-shaped expanse corresponding to semiconductor materials 16 and 92 contains a pair of prongs (or upwardly projecting sidewalls) 102 and 104 which join to a central (or base) region 106. Source region 94 is within sidewall 102, and drain region 96 is within sidewall 104. The source and drain regions are gatedly connected to one another through the central region 106. In operation, gates 86 and 88 are a front gate and back gate, respectively, that control current flow through the central region 106 between the source and drain regions. The central region 106 comprises a floating body of the floating body transistor 100. As can be understood with reference to Fig. 13, such floating body transistor is one of a plurality of identical floating body transistors. Such plurality of floating body transistors can form a memory array.

[0058] The construction of Fig. 38 can be considered to comprise a front gate/back gate pair (the front gate 86 and back gate 88) having a single trough-shaped semiconductor material slice (the slice corresponding to semiconductor materials 16 and 92) sandwiched therebetween.

[0059] The arrangement of Figs. 13-17 can be considered to include a series of electrically conductive plates, with the plates alternating between front gate plates and back gate plates; and to include an array of floating body transistors. The columns of the transistor array are between front gate plates and back gate plates. Each of the individual transistors along the columns has a source region and a drain region; and the source and drain regions of the transistors alternate with one another along the columns of the array.

[0060] Referring next to Figs. 18-21, an electrically insulative material 110 is formed across an upper surface of construction 10 and patterned to have openings 112 extending therethrough to source regions 94. Material 110 can comprise any suitable composition or combination of compositions, and in particular aspects can comprise, consist essentially of, or consist of silicon dioxide. Various structures underlying material 110 are shown in phantom in Fig. 18.

[0061] Referring next to Figs. 22-25, a series a source interconnect lines 120, 122, 124 and 126 are formed to electrically connect pluralities of the source regions 94 with one another. The source interconnect lines comprise conductive material 128 and electrically

insulative capping material 130. Sidewall spacers 132 are formed along sidewall edges of the materials 128 and 130.

[0062] Conductive material 128 can comprise any suitable composition or combination of compositions, and in particular aspects will comprise metals (such as tungsten or titanium), metal compositions (such as metal nitrides or metal silicides), and/or conductively-doped semiconductor material (such as, for example, conductively-doped silicon).

[0063] Electrically insulative cap 130 can comprise any suitable composition or combination of compositions, and in particular aspects will comprise, consist essentially of, or consist of silicon nitride.

[0064] Sidewall spacers 132 can comprise any suitable composition or combination of compositions, and in particular aspects will comprise, consist essentially of, or consist of one or both of silicon nitride and silicon dioxide.

[0065] In the shown aspect of the invention, conductive material 128 extends within openings 112 to partially fill the openings, but does not entirely fill the openings; and material 130 fills the remainder of the openings. It is to be understood that the invention can also include aspects in which material 128 entirely fills openings 112.

[0066] The source interconnect lines can be formed with any suitable processing. In particular aspects, layers of materials 128 and 130 are first formed across material 110 and within the openings 112, and such layers are then patterned into desired structures utilizing a photolithographically patterned photoresist mask (not shown) and a suitable etch, after which the photoresist mask is removed. Sidewall spacers 132 are then formed by providing a layer of appropriate material across the patterned structures of materials 128 and 130, and across material 110, followed by anisotropic etching to convert the layer into the sidewall spacers.

[0067] In the shown aspect of the invention, the source regions are interconnected along directions which extend at angles of about 45° relative to the latitudinal directions 32 and longitudinal directions 68 discussed above with reference to Fig. 9. In other words, the source regions of the floating body transistors are tied to one another along diagonals extending about 45 degrees to the columns of the transistor array of Figs. 13-17.

[0068] Referring to Figs. 26-29, electrically insulative material 140 is formed across material 110 and over the source interconnect lines; and subsequently is planarized so the material 140 is between but not over the source interconnect lines. Material 140 can comprise any suitable composition or combination of compositions, and in particular aspects, can comprise, consist essentially of, or consist of one or both of silicon nitride and silicon dioxide.

[0069] Openings 142 are etched through materials 140 and 110 to the drain regions 96, and subsequently such openings are filled with conductive material 144. The locations of the openings 142 can be defined with a photolithographically patterned photoresist mask (not shown) which is removed after formation of the openings.

[0070] Conductive material 144 can comprise any suitable composition or combination of compositions, and in particular aspects, will comprise metal, metal compositions, and/or conductively-doped semiconductor material. Conductive material 144 can be formed to fill the openings by initially providing the material to overfill the openings and then planarizing the material. Also, although the material is shown filling openings, it is to be understood that the conductive material can also be formed to line the openings rather than filling the openings in other aspects of the invention (not shown).

[0071] Referring next to Figs. 30-33, bitlines 150, 152, 154, 156, 158 and 160 are provided to electrically connect the drain regions 96 along the latitudinal directions 32 (Fig. 9). The bitlines comprise conductive material 162, and an insulative cap 164. The bitlines are surrounded by sidewall spacers 166. Conductive material 162 electrically contacts to drain regions 96 through conductive interconnects corresponding to material 144.

[0072] The conductive material 162 can comprise any suitable composition or combination of compositions, including, for example, metal, metal compounds, and/or conductively-doped semiconductor material.

[0073] Electrically insulative cap 164 can comprise any suitable composition or combination of compositions, and in particular aspects will comprise, consist essentially of, or consist of one or both of silicon nitride and silicon dioxide.

[0074] Sidewall spacers 166 can comprise any suitable composition or combination of compositions, and in particular aspects will comprise, consist essentially of, or consist of one or both of silicon dioxide and silicon nitride.

[0075] The bitlines can be patterned by forming layers of material 162 and 164 across an upper surface of construction 10, forming a photolithographically patterned photoresist mask over the layers to define locations of the bitlines, transferring a pattern from the mask to the layers to form the bitlines, and then removing the mask. The sidewall spacers can be formed by providing a layer of appropriate material over the bitlines and across the remainder of construction 10, and then subjecting such layer to anisotropic etching.

[0076] Referring next to Figs. 34-37, an electrically insulative material 170 is formed across construction 10, and subsequently openings 172, 174, 176, 178, 180, 182 and 184 are etched through the material to various conductive layers. The openings can be filled with appropriate electrically conductive interconnects to connect bitlines, back gates, front gates and source interconnects to appropriate circuitry to read and write from the memory array. Although the openings are shown being formed simultaneously, persons of ordinary skill in the art will recognize that the openings can be formed at different times relative to one another. Insulative material 170 can comprise any suitable composition or combination of compositions including, for example, silicon nitride and/or silicon dioxide.

[0077] A floating gate memory cell formed in accordance with aspects of the present invention can be accessed for reading and writing with any appropriate electrical parameters. For instance, a writing operation to write a "1" can be conducted with a front gate voltage of -2.0 volts, a drain voltage of 1.0 volt, and a back gate voltage of -1.0 volt. A writing operation to write a "0" can be conducted with a front gate voltage of 0.8 volts, a drain voltage of -1.0 volt, and a back gate voltage of -1.0 volt. A reading operation can be conducted with a front gate voltage of 0.8 volts, a drain voltage of 0.2 volts, and a back gate voltage of -1.0 volt. In such operations, the back gate is biased to -1.0 volt for hole retention in the floating body.

[0078] Although the shown configuration utilizes both front gates and back gates, it is to be understood that the back gates can be eliminated in some aspects of the invention. However, it can be advantageous to utilize the back gates to assist in reading and writing from the floating body transistors. It can be further advantageous if all of the back gates are electrically coupled to one another and thus easily maintained at an identical bias.

[0079] In the shown aspect the invention, at least some of the front gates are shared between pairs of floating body transistors on opposing sides of the front gates, and

similarly, at least some of the individual back gates are shared between pairs of floating body transistors on opposing sides of the back gates. This can enable high integration of memory arrays formed in accordance with aspects of the present invention.

[0080] Semiconductor assemblies in accordance with various aspects of the present invention can be utilized in numerous applications. For instance, the assemblies can be incorporated into various electronic systems, such as, for example, computer systems, phones, cars, airplanes, camcorders, cameras, medical devices, etc. The assemblies can provide various circuit functions within such systems, including memory and/or processing functions.

CLAIMS

1. A method of forming a semiconductor construction, comprising:
 - providing a substrate comprising first semiconductor material over an electrically insulative mass, the first semiconductor material having a thickness;
 - providing a patterned mask over the first semiconductor material, the mask comprising a layer of silicon nitride over a layer of silicon dioxide;
 - forming a plurality of first trenches extending into the first semiconductor material, but not entirely through the thickness of the first semiconductor material; the first trenches being U-shaped and extending primarily linearly along defined latitudinal directions;
 - forming one or more second trenches which extend entirely through the first semiconductor material and into the insulative mass; the forming of the second trenches leaving a plurality of spaced regions of the first semiconductor material extending along and under the first trenches; the individual spaced regions of first semiconductor material being trough-shaped with sidewalls of the troughs being along opposing sides of the first trenches, and bottoms of the troughs being under the first trenches;
 - overfilling the second trenches with electrically insulative material;
 - planarizing the electrically insulative material by polishing utilizing the layer of silicon nitride as a stop during the polishing;

after filling the second trenches, forming a plurality of third trenches entirely through the first semiconductor material and into the insulative mass extending primarily linearly along longitudinal directions substantially orthogonal to the latitudinal directions, the third trenches extending across the trough-shaped regions of the first semiconductor material and across the electrically insulative material, and thus having peripheries comprising insulative material regions and first semiconductor material regions; the third trenches dividing the trough-shaped first semiconductor material into trough-shaped slices;

lining the first semiconductor material regions of the third trench peripheries with dielectric material;

after the lining, forming conductive material within the third trenches;

removing the patterned mask and replacing the mask with a second semiconductor material, the second semiconductor material being the same composition as the first semiconductor material;

conductively doping the second semiconductor material to form source regions and drain regions;

conductively doping at least portions of the sidewalls of the trough-shaped regions of the first semiconductor material; and

wherein the conductive material within the third trenches forms a plurality of front-gate/back-gate pairs, with each pair sandwiching a single of the trough-shaped slices therebetween; each sandwich of a front-gate/trough-shaped first semiconductor material slice/back-gate being a floating body transistor unit cell.

2. A method of forming a semiconductor construction, comprising:

providing a substrate comprising first semiconductor material over an electrically insulative mass, the first semiconductor material having a thickness;

providing a patterned mask comprising silicon dioxide and silicon nitride over the first semiconductor material;

forming a plurality of first trenches extending into the first semiconductor material, but not entirely through the thickness of the first semiconductor material; the first trenches being U-shaped and extending primarily linearly along defined latitudinal directions;

forming one or more second trenches which extend entirely through the first semiconductor material and into and about half way through the insulative mass; the forming of the second trenches leaving a plurality of spaced regions of the first semiconductor material extending along and under the first trenches; the individual spaced regions of first semiconductor material being trough-shaped with sidewalls of the troughs being along opposing sides of the first trenches, and bottoms of the troughs being under the first trenches;

overfilling the second trenches with electrically insulative material;
planarizing the electrically insulative material utilizing the mask as a stop;

after filling the second trenches, forming a plurality of third trenches entirely through the first semiconductor material and about half way through the insulative mass extending primarily linearly along longitudinal directions substantially orthogonal to the latitudinal directions, the third trenches extending across the trough-shaped regions of the first semiconductor material and across the electrically insulative material, and thus having peripheries comprising insulative material regions and first semiconductor material regions; the third trenches dividing the trough-shaped first semiconductor material into trough-shaped slices;

lining the first semiconductor material regions of the third trench peripheries with dielectric material;

after the lining, forming conductive material within the third trenches;

removing the patterned mask and replacing the mask with a second semiconductor material, the second semiconductor material being the same composition as the first semiconductor material;

conductively doping the second semiconductor material to form source regions and drain regions;

conductively doping at least portions of the sidewalls of the trough-shaped regions of the semiconductor material;

wherein the conductive material within the third trenches forms a plurality of front-gate/back-gate pairs, with each pair sandwiching a single of the trough-shaped slices therebetween; each sandwich of a front-gate/trough-shaped first semiconductor material slice/back-gate being a floating body transistor unit cell;

wherein the conductively-doped portions of the sidewalls are part of source and drain regions; and

wherein each trough-shaped semiconductor material slice has a source region in one sidewall of the slice and a drain region in the other sidewall of the slice.

3. The method of claim 2 further comprising electrically interconnecting pluralities of the source regions along directions extending diagonally to the longitudinal and latitudinal directions.

4. The method of claim 2 further comprising electrically interconnecting pluralities of the drain regions along a common latitudinal direction.

5. The method of claim 2 further comprising:

electrically interconnecting pluralities of the source regions along directions extending diagonally to the longitudinal and latitudinal directions with source interconnect lines; and

electrically interconnecting pluralities of the drain regions along common latitudinal directions with bitlines.

6. The method of claim 5 wherein the bitlines are over the source interconnect lines.

7. The method of claim 1 wherein forming the conductive material within the third trenches only partially fills the third trenches to leave upper portions of the third trenches which are not filled; and further comprising forming electrically insulative caps within the upper portions of the third trenches.

8. The method of claim 1 wherein the first trenches are filled with the insulative material during the filling of the second trenches with the insulative material.

9. The method of claim 1 further comprising electrically connecting all of the back-gates to one another.

10. The method of claim 1 wherein the insulative mass is over a semiconductor base; wherein the insulative mass consists of silicon dioxide; and wherein the semiconductor base comprises monocrystalline silicon.
