

SYSTEMS USING CELL CULTURE FOR PRODUCTION OF ISOPRENE

CROSS-REFERENCE TO RELATED APPLICATIONS

[001] This applications claims the benefit of U.S. Provisional patent application 61/097,163, filed on September 15, 2008, and U.S. Provisional patent application 61/187,832, filed on June 17, 2009, the contents of both are hereby incorporated by reference in its entirety.

[002] BACKGROUND OF THE INVENTION

[003] Isoprene (2-methyl-1,3-butadiene) is the critical starting material for a variety of synthetic polymers, most notably synthetic rubbers. Isoprene is naturally produced by a variety of microbial, plant, and animal species. In particular, two pathways have been identified for the biosynthesis of isoprene: the mevalonate (MVA) pathway and the non-mevalonate (DXP) pathway (Figures 19A and 19B). However, the yield of isoprene from naturally-occurring organisms is commercially unattractive. About 800,000 tons per year of *cis*-polyisoprene are produced from the polymerization of isoprene; most of this polyisoprene is used in the tire and rubber industry. Isoprene is also copolymerized for use as a synthetic elastomer in other products such as footwear, mechanical products, medical products, sporting goods, and latex.

[004] Currently, the tire and rubber industry is based on the use of natural and synthetic rubber. Natural rubber is obtained from the milky juice of rubber trees or plants found in the rainforests of Africa. Synthetic rubber is based primarily on butadiene polymers. For these polymers, butadiene is obtained as a co-product from ethylene and propylene manufacture.

[005] While isoprene can be obtained by fractionating petroleum, the purification of this material is expensive and time-consuming. Petroleum cracking of the C5 stream of hydrocarbons produces only about 15% isoprene. Thus, more economical methods for producing isoprene are needed. In particular, methods that produce isoprene at rates, titers, and purity that are sufficient to meet the demands of a robust commercial process are desirable. Also desired are systems for producing isoprene from inexpensive starting materials.

[006] The invention provided herein addresses these needs and provides additional benefits as well.

BRIEF SUMMARY OF THE INVENTION

[007] The invention provides for, *inter alia*, compositions, systems, cells and methods for producing a compound having one or both of the following characteristics: (a) a Henry's law coefficient of less than about 250 M/atm and/or (b) a solubility in water of less than about 100 g/L. In one embodiment, the compound is isoprene. In another embodiment, the compound is ethylene. The invention also provides for methods of producing isoprene comprising: a) culturing cells under suitable conditions for production of isoprene; and b) producing isoprene, wherein cells produce greater than about 400 nmole/g_{wcm}/hour of isoprene, and the carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. In some embodiments, the methods further comprise recovering the compound, such as isoprene. In one embodiment, the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an isoprene synthase polypeptide. In another embodiment, the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an IDI polypeptide, an MVA pathway enzyme, or a DXP pathway enzyme. In another embodiment, the MVA pathway enzyme is mevalonate kinase.

[008] Further provided herein are methods of producing isoprene comprising: a) culturing cells under suitable conditions for production of isoprene; and b) producing isoprene, wherein the cumulative total productivity of the isoprene produced by the cells in culture is greater than about 0.2 mg/L_{broth}/hour and the carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. In some embodiments, the methods further comprise recovering the isoprene. In one embodiment, the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an isoprene synthase polypeptide. In another embodiment, the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an IDI polypeptide, an MVA pathway enzyme, or a DXP pathway enzyme. In another embodiment, the MVA pathway enzyme is mevalonate kinase.

[009] Methods of producing isoprene are also provided herein comprising: a) culturing cells under suitable conditions for production of isoprene; and b) producing isoprene, wherein the peak concentration of the isoprene produced by the cells in culture is greater than about 10 ng/L_{broth} and the carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. In some embodiments of any of these methods, the carbon dioxide evolution rate is between about any of 1×10^{-18} mmol/L/hour to about 1 mol/L/hour, 1 mmol/L/hour to 1 mol/L/hour, 25 mmol/L/hour to 750 mmol/L/hour, 25 mmol/L/hour to 75 mmol/L/hour, 250 mmol/L/hour to 750 mmol/L/hour, or 450 mmol/L/hour to 550 mmol/L/hour. In some embodiments, the carbon dioxide evolution rate is about 50 mmol/L/hour or about 500 mmol/L/hour. In some embodiments, the methods further comprise recovering the isoprene. In one embodiment, the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an isoprene synthase polypeptide. In another embodiment, the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an IDI polypeptide, an MVA pathway enzyme, or a DXP pathway enzyme. In another embodiment, the MVA pathway enzyme is mevalonate kinase.

[010] Further provided herein are cells in culture comprising a nucleic acid encoding an isoprene synthase polypeptide, wherein the cells produce greater than about 400 nmole/g_{wcm}/hour of isoprene and carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. Provided herein are also cells in culture comprising a nucleic acid encoding an isoprene synthase polypeptide, wherein cumulative total productivity of the isoprene produced by the cells in culture is greater than about 0.2 mg/L_{broth}/hour and carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. In addition, provided herein are cells in culture comprising a nucleic acid encoding an isoprene synthase polypeptide, wherein peak concentration of the isoprene produced by the cells in culture is greater than about 10 ng/L_{broth} and carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. In some embodiments of any of these cells in culture, the carbon dioxide evolution rate is between about any of 1×10^{-18} mmol/L/hour to about 1 mol/L/hour, 1 mmol/L/hour to 1 mol/L/hour, 25 mmol/L/hour to 750 mmol/L/hour, 25 mmol/L/hour to 75 mmol/L/hour, 250 mmol/L/hour to 750 mmol/L/hour, or 450 mmol/L/hour to 550 mmol/L/hour. In some embodiments, the carbon dioxide evolution rate is about 50 mmol/L/hour or about 500 mmol/L/hour. The invention

also provides for composition and/or systems comprising one or more of any of the cells disclosed herein.

[011] Provided herein are also methods of producing isoprene comprising a) culturing cells under suitable conditions for production of isoprene; and b) producing isoprene, wherein the liquid phase concentration of isoprene is less than about 2 g/L and the cells produce greater than about 400 nmole/g_{wcm}/hour of isoprene. In some embodiments, the liquid phase concentration of isoprene in the culture is less than about 1 g/L. In some embodiments, the liquid phase concentration of isoprene in the culture is less than about 200 mg/L. In some embodiments, the liquid phase concentration of isoprene in the culture is less than any of about 1.9 g/L, 1.8 g/L, 1.7 g/L, 1.6 g/L, 1.5 g/L, 1.4 g/L, 1.3 g/L, 1.2 g/L, or 1.1 g/L. In some embodiments, the liquid phase concentration of isoprene in the culture is less than any of about 900 mg/L, 800 mg/L, 700 mg/L, 600 mg/L, 500 mg/L, 400 mg/L, or 300 mg/L. In some embodiments, the liquid phase concentration of isoprene in the culture is less than about any of 175 mg/L, 150 mg/L, 125 mg/L, 100 mg/L, 75 mg/L, 50 mg/L, 25 mg/L, 20 mg/L, 15 mg/L, 10 mg/L, 5 mg/L, or 2.5 mg/L. In some embodiments, the liquid phase concentration of isoprene in culture is between about any of 0.1 mg/L to 200 mg/L, 1 mg/L to 200 mg/L, 1 mg/L to 150 mg/L, 1 mg/L to 100 mg/L, 1 mg/L to 50 mg/L, 1 mg/L to 25 mg/L, 1 mg/L to 20 mg/L, or 10 mg/L to 20 mg/L, 1 mg/L to 1 g/L, 0.1 mg/L to 2 g/L, 1 g/L to 2 g/L, 10 mg/L to 1 g/L, or 100 mg/L to 1 g/L. In some embodiments, the liquid phase concentration is below the solubility limit of isoprene. In some embodiments, the liquid phase in the culture is saturated with isoprene, and isoprene is additionally present in a second liquid phase. In some embodiments, the second liquid phase comprises at least about 50, 60, 70, 80, 85, 90, 95, or 98% isoprene. In some embodiments, the methods further comprise recovering the isoprene. In one embodiment, the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an isoprene synthase polypeptide. In another embodiment, the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an IDI polypeptide, an MVA pathway enzyme, or a DXP pathway enzyme. In another embodiment, the MVA pathway enzyme is mevalonate kinase.

[012] Also provided herein are methods of producing a compound, wherein the compound has one or more characteristics selected from the group consisting of (a) a Henry's law

coefficient of less than about 250 M/atm and (b) a solubility in water of less than about 100 g/L. In some embodiments, the method comprises: a) culturing cells under suitable conditions for production of the compound, wherein gas is added (such as the addition of gas to a system such as a fermentation system) at a gas sparging rate between about 0.01 vvm to about 2 vvm; and b) producing the compound. In one embodiment, anaerobic conditions are used. In another embodiment, the gas sparging rate is 0 vvm. In another embodiment, the gas sparging rate is 0 vvm – 0.01 vvm. In other embodiments, the method comprises: a) culturing cells under suitable conditions for production of the compound; b) producing the compound; and c) recovering the compound in the gas phase. In some embodiments, the method comprises: a) culturing cells under suitable conditions for production of the compound; b) producing the compound; and c) recovering the compound from the gas phase. In one embodiment, the compound produced is ethylene. In some embodiments, the Henry's law coefficient of the compound is less than about any of 200 M/atm, 150 M/atm, 100 M/atm, 75 M/atm, 50 M/atm, 25 M/atm, 10 M/atm, 5 M/atm, or 1 M/atm. In some embodiments, the solubility in water of the compound is less than about any of 75 g/L, 50 g/L, 25 g/L, 10 g/L, 5 g/L, or 1g/L. In some embodiments, the compound is selected from a group consisting of isoprene, an aldehyde (*e.g.*, acetaldehyde), a ketone (*e.g.*, acetone, methyl ethyl ketone or 2-butanone), an alcohol (*e.g.*, methanol, ethanol, 1-butanol, or C5 alcohols such as 3-methyl-3-buten-1-ol or 3-methyl-2-buten-1-ol), an ester of an alcohol (*e.g.*, ethyl acetate, esters of 3-methyl-2-buten-1-ol, or acetyl esters of C5 alcohols), a hemiterpene, a monoterpene, a sesquiterpene, and C1 to C5 hydrocarbons (*e.g.*, methane, ethane, ethylene, or propylene). In some embodiments, the C1 to C5 hydrocarbons are saturated, unsaturated, or branched. In some embodiments, the C1 to C5 hydrocarbon is an unsaturated aliphatic hydrocarbon (*e.g.* ethylene, propene, butylene, or isobutylene). In some embodiments the C1 to C5 hydrocarbon is a diolefin. In particular embodiments, the compound is isoprene. In other particular embodiments, the compound is ethylene. In some embodiments of the methods of producing any of the compounds described above, the gas sparging rate is between about any of 0 vvm to 0.1 vvm, 0.1 vvm to 1 vvm, 0.2 vvm to 1 vvm, or 0.5 vvm to 1 vvm. In some embodiments of the methods of producing any of the compounds described above, the gas sparging rate is 0.0 vvm.

[013] In one aspect, the invention features methods of producing ethylene. In some embodiments, the method comprises: a) culturing cells under suitable conditions for

production of ethylene, wherein gas is added (such as the addition of gas to a system such as a fermentation system) at a gas sparging rate between about 0.01 vvm to about 2 vvm; b) producing ethylene. In other embodiments, the method comprises: a) culturing cells under suitable conditions for production of ethylene; and b) producing ethylene; and c) recovering the ethylene in the gas phase. In some embodiments of the methods of producing ethylene, the gas sparging rate is between about any of 0 vvm to 0.1 vvm, 0.1 vvm to 1 vvm, 0.2 vvm to 1 vvm, or 0.5 vvm to 1 vvm. In some embodiments of the methods of producing ethylene, the gas sparging rate is 0.0 vvm.

[014] In any of the embodiments, the methods further comprise recovering the isoprene and/or ethylene. In some embodiments, ethylene is recovered by adsorption. In a particular embodiment, ethylene is adsorbed on a silver-modified clay. In other embodiments, ethylene is recovered by cryogenic separation or absorption/stripping.

[015] In one aspect, the invention features cells in culture that produce isoprene. In some embodiments, the invention provides cells in culture that produce greater than about 400 nmole of isoprene/gram of cells for the wet weight of the cells/hour (nmole/g_{wcm}/hr) of isoprene. In some embodiments, the cells have a heterologous nucleic acid that (i) encodes an isoprene synthase polypeptide and (ii) is operably linked to a promoter. In some embodiments, the cells are cultured in a culture medium that includes a carbon source, such as, but not limited to, a carbohydrate, glycerol, glycerine, dihydroxyacetone, one-carbon source, oil, animal fat, animal oil, fatty acid, lipid, phospholipid, glycerolipid, monoglyceride, diglyceride, triglyceride, renewable carbon source, polypeptide (*e.g.*, a microbial or plant protein or peptide), yeast extract, component from a yeast extract, or any combination of two or more of the foregoing. In some embodiments, the cells are cultured under limited glucose conditions.

[016] In some embodiments, the invention provides cells in culture that convert more than about 0.002% of the carbon in a cell culture medium into isoprene. In some embodiments, the cells have a heterologous nucleic acid that (i) encodes an isoprene synthase polypeptide and (ii) is operably linked to a promoter. In some embodiments, the cells are cultured in a culture medium that includes a carbon source, such as, but not limited to, a carbohydrate, glycerol, glycerine, dihydroxyacetone, one-carbon source, oil, animal fat, animal oil, fatty acid, lipid, phospholipid, glycerolipid, monoglyceride, diglyceride, triglyceride, renewable carbon source, polypeptide (*e.g.*, a microbial or plant protein or

peptide), yeast extract, component from a yeast extract, or any combination of two or more of the foregoing. In some embodiments, the cells are cultured under limited glucose conditions.

[017] In some embodiments, the invention provides cells in culture that comprise a heterologous nucleic acid encoding an isoprene synthase polypeptide. In some embodiments, the cells have a heterologous nucleic acid that (i) encodes an isoprene synthase polypeptide and (ii) is operably linked to a promoter. In some embodiments, the cells are cultured in a culture medium that includes a carbon source, such as, but not limited to, a carbohydrate, glycerol, glycerine, dihydroxyacetone, one-carbon source, oil, animal fat, animal oil, fatty acid, lipid, phospholipid, glycerolipid, monoglyceride, diglyceride, triglyceride, renewable carbon source, polypeptide (*e.g.*, a microbial or plant protein or peptide), yeast extract, component from a yeast extract, or any combination of two or more of the foregoing. In some embodiments, the cells are cultured under limited glucose conditions.

[018] In one aspect, the invention features cells in culture that produce a compound, wherein the compound has one or more characteristics selected from the group consisting of (a) a Henry's law coefficient of less than about 250 M/atm and (b) a solubility in water of less than about 100 g/L. In some embodiments, the cells have a heterologous nucleic acid that (i) encodes a synthase polypeptide capable of producing the compound and (ii) is operably linked to a promoter. In some embodiments, the compound produced is ethylene and the synthase polypeptide is ethylene-forming enzyme (efe). In some embodiments, the cells are cultured in a culture medium that includes one or more carbon source(s), such as, but not limited to, a carbohydrate, glycerol, glycerine, dihydroxyacetone, one-carbon source, oil, animal fat, animal oil, fatty acid, lipid, phospholipid, glycerolipid, monoglyceride, diglyceride, triglyceride, renewable carbon source, polypeptide (*e.g.*, a microbial or plant protein or peptide), yeast extract, component from a yeast extract. In some embodiments, the cells are cultured under limited glucose conditions.

[019] In one aspect, the invention features methods of producing isoprene, such as methods of using any of the cells described herein to produce isoprene. In some embodiments, the method involves culturing cells under conditions sufficient to produce greater than about 400 nmole/g_{wcm}/hr of isoprene. In some embodiments, the method also includes recovering isoprene produced by the cells. In some embodiments, the method includes purifying

isoprene produced by the cells. In some embodiments, the method includes polymerizing the isoprene. In some embodiments, the cells have a heterologous nucleic acid that (i) encodes an isoprene synthase polypeptide and (ii) is operably linked to a promoter. In some embodiments, the cells are cultured in a culture medium that includes a carbon source, such as, but not limited to, a carbohydrate, glycerol, glycerine, dihydroxyacetone, one-carbon source, oil, animal fat, animal oil, fatty acid, lipid, phospholipid, glycerolipid, monoglyceride, diglyceride, triglyceride, renewable carbon source, polypeptide (*e.g.*, a microbial or plant protein or peptide), yeast extract, component from a yeast extract, or any combination of two or more of the foregoing. In some embodiments, the cells are cultured under limited glucose conditions. In various embodiments, the amount of isoprene produced (such as the total amount of isoprene produced or the amount of isoprene produced per liter of broth per hour per OD₆₀₀) during stationary phase is greater than or about 2 or more times the amount of isoprene produced during the growth phase for the same length of time. In some embodiments, the gas phase comprises greater than or about 9.5 % (volume) oxygen, and the concentration of isoprene in the gas phase is less than the lower flammability limit or greater than the upper flammability limit. In particular embodiments, (i) the concentration of isoprene in the gas phase is less than the lower flammability limit or greater than the upper flammability limit, and (ii) the cells produce greater than about 400 nmole/g_{wcm}/hr of isoprene.

[020] In some embodiments, the method includes culturing cells under conditions sufficient to convert more than about 0.002% of the carbon (mol/mol) in a cell culture medium into isoprene. In some embodiments, the method also includes recovering isoprene produced by the cells. In some embodiments, the method includes purifying isoprene produced by the cells. In some embodiments, the method includes polymerizing the isoprene. In some embodiments, the cells have a heterologous nucleic acid that (i) encodes an isoprene synthase polypeptide and (ii) is operably linked to a promoter. In some embodiments, the cells are cultured in a culture medium that includes a carbon source, such as, but not limited to, a carbohydrate, glycerol, glycerine, dihydroxyacetone, one-carbon source, oil, animal fat, animal oil, fatty acid, lipid, phospholipid, glycerolipid, monoglyceride, diglyceride, triglyceride, renewable carbon source, polypeptide (*e.g.*, a microbial or plant protein or peptide), yeast extract, component from a yeast extract, or any combination of two or more of the foregoing. In some embodiments, the cells are cultured under limited glucose conditions.

[021] In some embodiments, isoprene is only produced in stationary phase. In some embodiments, isoprene is produced in both the growth phase and stationary phase. In various embodiments, the amount of isoprene produced (such as the total amount of isoprene produced or the amount of isoprene produced per liter of broth per hour per OD₆₀₀) during stationary phase is greater than or about 2, 3, 4, 5, 10, 20, 30, 40, 50, or more times the amount of isoprene produced during the growth phase for the same length of time.

[022] In one aspect, the invention features methods of producing a compound, wherein the compound has one or more characteristics selected from the group consisting of (a) a Henry's law coefficient of less than about 250 M/atm and (b) a solubility in water of less than about 100 g/L, such as methods of using any of the cells described herein to produce the compound. In some embodiments, the compound produced is ethylene. In some embodiments, the method also includes recovering the compound produced by the cells. In some embodiments, the method includes purifying the compound produced by the cells. In some embodiments, the method includes polymerizing the compound. In some embodiments, the cells have a heterologous nucleic acid that (i) encodes a synthase polypeptide capable of producing the compound and (ii) is operably linked to a promoter. In a particular embodiment, the heterologous nucleic acid encodes efe. In some embodiments, the cells are cultured in a culture medium that includes one or more carbon source(s), such as, but not limited to, a carbohydrate, glycerol, glycerine, dihydroxyacetone, one-carbon source, oil, animal fat, animal oil, fatty acid, lipid, phospholipid, glycerolipid, monoglyceride, diglyceride, triglyceride, renewable carbon source, polypeptide (*e.g.*, a microbial or plant protein or peptide), yeast extract, component from a yeast extract,. In some embodiments, the cells are cultured under limited glucose conditions. In various embodiments, the amount of the compound produced (such as the total amount of the compound produced or the amount of the compound produced per liter of broth per hour per OD₆₀₀) during stationary phase is greater than or about 2 or more times the amount of the compound produced during the growth phase for the same length of time. In some embodiments, the gas phase comprises greater than or about 9.5 % (volume) oxygen, and the concentration of the compound in the gas phase is less than the lower flammability limit or greater than the upper flammability limit.

[023] In some embodiments, the compound is only produced in stationary phase. In some embodiments, the compound is produced in both the growth phase and stationary phase. In various embodiments, the amount of the compound produced (such as the total amount of isoprene produced or the amount of isoprene produced per liter of broth per hour per OD₆₀₀) during stationary phase is greater than or about 2, 3, 4, 5, 10, 20, 30, 40, 50, or more times the amount of the compound produced during the growth phase for the same length of time.

[024] In one aspect, the invention features compositions and systems that comprise isoprene. In some embodiments, the composition comprises greater than or about 2, 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 200, 300, 400, 500, 600, 700, 800, 900, or 1000 mg of isoprene. In some embodiments, the composition comprises greater than or about 2, 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100 g of isoprene(w/w) of the volatile organic fraction of the composition is isoprene.

[025] In some embodiments, the composition comprises greater than or about 99.90, 99.92, 99.94, 99.96, 99.98, or 100% isoprene by weight compared to the total weight of all C5 hydrocarbons in the composition. In some embodiments, the composition comprises less than or about 0.12, 0.10, 0.08, 0.06, 0.04, 0.02, 0.01, 0.005, 0.001, 0.0005, 0.0001, 0.00005, or 0.00001% C5 hydrocarbons other than isoprene (such 1,3-cyclopentadiene, *trans*-1,3-pentadiene, *cis*-1,3-pentadiene, 1,4-pentadiene, 1-pentyne, 2-pentyne, 3-methyl-1-butyne, pent-4-ene-1-yne, *trans*-pent-3-ene-1-yne, *cis*-pent-3-ene-1-yne, 3-hexen-1-ol, 3-hexen-1-yl acetate, limonene, geraniol (*trans*-3,7-dimethyl-2,6-octadien-1-ol) and citronellol (3,7-dimethyl-6-octen-1-ol)) by weight compared to the total weight of all C5 hydrocarbons in the composition. In some embodiments, the composition has less than or about 0.12, 0.10, 0.08, 0.06, 0.04, 0.02, 0.01, 0.005, 0.001, 0.0005, 0.0001, 0.00005, or 0.00001% for 1,3-cyclopentadiene, *trans*-1,3-pentadiene, *cis*-1,3-pentadiene, 1,4-pentadiene, 1-pentyne, 2-pentyne, 3-methyl-1-butyne, pent-4-ene-1-yne, *trans*-pent-3-ene-1-yne, *cis*-pent-3-ene-1-yne, 3-hexen-1-ol, 3-hexen-1-yl acetate, limonene, geraniol (*trans*-3,7-dimethyl-2,6-octadien-1-ol) and citronellol (3,7-dimethyl-6-octen-1-ol) by weight compared to the total weight of all C5 hydrocarbons in the composition. In particular embodiments, the composition has greater than about 2 mg of isoprene and has greater than or about 99.90, 99.92, 99.94, 99.96, 99.98, or 100% isoprene by weight compared to the total weight of all C5 hydrocarbons in the composition.

[026] In some embodiments, the composition has less than or about 50, 40, 30, 20, 10, 5, 1, 0.5, 0.1, 0.05, 0.01, or 0.005 ug/L of a compound that inhibits the polymerization of isoprene for any compound in the composition that inhibits the polymerization of isoprene. In particular embodiments, the composition also has greater than about 2 mg of isoprene.

[027] In some embodiments, the composition has one or more compounds selected from the group consisting of ethanol, acetone, C5 prenyl alcohols, and isoprenoid compounds with 10 or more carbon atoms. In some embodiments, the composition has greater than or about 0.005, 0.01, 0.05, 0.1, 0.5, 1, 5, 10, 20, 30, 40, 60, 80, 100, or 120 ug/L of ethanol, acetone, a C5 prenyl alcohol (such as 3-methyl-3-buten-1-ol or 3-methyl-2-buten-1-ol), or any two or more of the foregoing. In particular embodiments, the composition has greater than about 2 mg of isoprene and has one or more compounds selected from the group consisting of ethanol, acetone, C5 prenyl alcohols, and isoprenoid compounds with 10 or more carbon atoms.

[028] In some embodiments, the composition includes isoprene and one or more second compounds selected from the group consisting of 2-heptanone, 6-methyl-5-hepten-2-one, 2,4,5-trimethylpyridine, 2,3,5-trimethylpyrazine, citronellal, acetaldehyde, methanethiol, methyl acetate, 1-propanol, diacetyl, 2-butanone, 2-methyl-3-buten-2-ol, ethyl acetate, 2-methyl-1-propanol, 3-methyl-1-butanal, 3-methyl-2-butanone, 1-butanol, 2-pentanone, 3-methyl-1-butanol, ethyl isobutyrate, 3-methyl-2-butenal, butyl acetate, 3-methylbutyl acetate, 3-methyl-3-buten-1-yl acetate, 3-methyl-2-buten-1-yl acetate, (E)-3,7-dimethyl-1,3,6-octatriene, (Z)-3,7-dimethyl-1,3,6-octatriene, and 2,3-cycloheptenolpyridine. In various embodiments, the amount of one of these second components relative to the amount of isoprene in units of percentage by weight (*i.e.*, weight of the component divided by the weight of isoprene times 100) is at greater than or about 0.01, 0.02, 0.05, 0.1, 0.5, 1, 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, or 110% (w/w).

[029] In some embodiments, the composition comprises (i) a gas phase that comprises isoprene and (ii) cells in culture that produce greater than about 400 nmole/g_{wcm}/hr of isoprene. In some embodiments, the composition comprises a closed system, and the gas phase comprises greater than or about 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100 ug/L of isoprene when normalized to 1 mL of 1 OD₆₀₀ cultured for 1 hour. In some embodiments, the composition comprises an open system, and the gas phase comprises greater than or about 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100 ug/L of isoprene when sparged at a rate of 1

vvm. In some embodiments, the volatile organic fraction of the gas phase comprises greater than or about 99.90, 99.92, 99.94, 99.96, 99.98, or 100% isoprene by weight compared to the total weight of all C5 hydrocarbons in the volatile organic fraction. In some embodiments, the volatile organic fraction of the gas phase comprises less than or about 0.12, 0.10, 0.08, 0.06, 0.04, 0.02, 0.01, 0.005, 0.001, 0.0005, 0.0001, 0.00005, or 0.00001% C5 hydrocarbons other than isoprene (such 1,3-cyclopentadiene, *trans*-1,3-pentadiene, *cis*-1,3-pentadiene, 1,4-pentadiene, 1-pentyne, 2-pentyne, 3-methyl-1-butyne, pent-4-ene-1-yne, *trans*-pent-3-ene-1-yne, *cis*-pent-3-ene-1-yne, 3-hexen-1-ol, 3-hexen-1-yl acetate, limonene, geraniol (trans-3,7-dimethyl-2,6-octadien-1-ol) and citronellol (3,7-dimethyl-6-octen-1-ol)) by weight compared to the total weight of all C5 hydrocarbons in the volatile organic fraction. In some embodiments, the volatile organic fraction of the gas phase has less than or about 0.12, 0.10, 0.08, 0.06, 0.04, 0.02, 0.01, 0.005, 0.001, 0.0005, 0.0001, 0.00005, or 0.00001% for 1,3-cyclopentadiene, *trans*-1,3-pentadiene, *cis*-1,3-pentadiene, 1,4-pentadiene, 1-pentyne, 2-pentyne, 3-methyl-1-butyne, pent-4-ene-1-yne, *trans*-pent-3-ene-1-yne, *cis*-pent-3-ene-1-yne, 3-hexen-1-ol, 3-hexen-1-yl acetate, limonene, geraniol (trans-3,7-dimethyl-2,6-octadien-1-ol) and citronellol (3,7-dimethyl-6-octen-1-ol) by weight compared to the total weight of all C5 hydrocarbons in the volatile organic fraction. In particular embodiments, the volatile organic fraction of the gas phase has greater than about 2 mg of isoprene and has greater than or about 99.90, 99.92, 99.94, 99.96, 99.98, or 100% isoprene by weight compared to the total weight of all C5 hydrocarbons in the volatile organic fraction.

[030] In some embodiments, the volatile organic fraction of the gas phase has less than or about 50, 40, 30, 20, 10, 5, 1, 0.5, 0.1, 0.05, 0.01, or 0.005 ug/L of a compound that inhibits the polymerization of isoprene for any compound in the volatile organic fraction of the gas phase that inhibits the polymerization of isoprene. In particular embodiments, the volatile organic fraction of the gas phase also has greater than about 2 mg of isoprene.

[031] In some embodiments, the volatile organic fraction of the gas phase has one or more compounds selected from the group consisting of ethanol, acetone, C5 prenyl alcohols, and isoprenoid compounds with 10 or more carbon atoms. In some embodiments, the volatile organic fraction of the gas phase has greater than or about 0.005, 0.01, 0.05, 0.1, 0.5, 1, 5, 10, 20, 30, 40, 60, 80, 100, or 120 ug/L of ethanol, acetone, a C5 prenyl alcohol (such as 3-methyl-3-buten-1-ol or 3-methyl-2-buten-1-ol), or any two or more of the foregoing. In

particular embodiments, the volatile organic fraction of the gas phase has greater than about 2 mg of isoprene and has one or more compounds selected from the group consisting of ethanol, acetone, C5 prenyl alcohols, and isoprenoid compounds with 10 or more carbon atoms.

[032] In some embodiments, the volatile organic fraction of the gas phase has includes isoprene and one or more second compounds selected from the group consisting of 2-heptanone, 6-methyl-5-hepten-2-one, 2,4,5-trimethylpyridine, 2,3,5-trimethylpyrazine, citronellal, acetaldehyde, methanethiol, methyl acetate, 1-propanol, diacetyl, 2-butanone, 2-methyl-3-buten-2-ol, ethyl acetate, 2-methyl-1-propanol, 3-methyl-1-butanal, 3-methyl-2-butanone, 1-butanol, 2-pentanone, 3-methyl-1-butanol, ethyl isobutyrate, 3-methyl-2-butanal, butyl acetate, 3-methylbutyl acetate, 3-methyl-3-buten-1-yl acetate, 3-methyl-2-buten-1-yl acetate, (E)-3,7-dimethyl-1,3,6-octatriene, (Z)-3,7-dimethyl-1,3,6-octatriene, and 2,3-cycloheptenolpyridine. In various embodiments, the amount of one of these second components relative to amount of isoprene in units of percentage by weight (*i.e.*, weight of the component divided by the weight of isoprene times 100) is at greater than or about 0.01, 0.02, 0.05, 0.1, 0.5, 1, 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, or 110% (w/w) in the volatile organic fraction of the gas phase.

[033] In some embodiments of any of the compositions of the invention, at least a portion of the isoprene is in a gas phase. In some embodiments, at least a portion of the isoprene is in a liquid phase (such as a condensate). In some embodiments, at least a portion of the isoprene is in a solid phase. In some embodiments, at least a portion of the isoprene is adsorbed to a solid support, such as a support that includes silica and/or activated carbon. In some embodiments, the composition includes ethanol. In some embodiments, the composition includes between about 75 to about 90% by weight of ethanol, such as between about 75 to about 80%, about 80 to about 85%, or about 85 to about 90% by weight of ethanol. In some embodiments, the composition includes between about 4 to about 15% by weight of isoprene, such as between about 4 to about 8%, about 8 to about 12%, or about 12 to about 15% by weight of isoprene.

[034] In some embodiments, the invention also features systems that include any of the cells and/or compositions described herein. In some embodiments, the system includes a reactor that chamber comprises cells in culture that produce greater than about 400, 500, 600, 700, 800, 900, 1,000, 1,250, 1,500, 1,750, 2,000, 2,500, 3,000, 4,000, 5,000, or more

nmole/g_{wcm}/hr isoprene. In some embodiments, the system is not a closed system. In some embodiments, at least a portion of the isoprene is removed from the system. In some embodiments, the system includes a gas phase comprising isoprene. In various embodiments, the gas phase comprises any of the compositions described herein.

[035] In one aspect, the invention provides a tire comprising polyisoprene. In some embodiments, the polyisoprene is produced by (i) polymerizing isoprene in any of the compositions described herein or (ii) polymerizing isoprene recovered from any of the compositions described herein. In some embodiments, the polyisoprene comprises *cis*-1,4-polyisoprene. In another aspect, the invention provides methods of manufacturing a tire wherein the improvement comprises using any one or more the compositions, cells, systems and/or methods described herein to produce isoprene for the manufacture of the tire.

[036] In some embodiments of any of the compositions, systems, and methods of the invention, a nonflammable concentration of isoprene in the gas phase is produced. In some embodiments, the gas phase comprises less than about 9.5 % (volume) oxygen. In some embodiments, the gas phase comprises greater than or about 9.5 % (volume) oxygen, and the concentration of isoprene in the gas phase is less than the lower flammability limit or greater than the upper flammability limit. In some embodiments, the portion of the gas phase other than isoprene comprises between about 0% to about 100% (volume) oxygen, such as between about 10% to about 100% (volume) oxygen. In some embodiments, the portion of the gas phase other than isoprene comprises between about 0% to about 99% (volume) nitrogen. In some embodiments, the portion of the gas phase other than isoprene comprises between about 1% to about 50% (volume) CO₂.

[037] In some embodiments of any of the aspects of the invention, the cells in culture produce isoprene at greater than or about 400, 500, 600, 700, 800, 900, 1,000, 1,250, 1,500, 1,750, 2,000, 2,500, 3,000, 4,000, 5,000, or more nmole/g_{wcm}/hr isoprene. In some embodiments of any of the aspects of the invention, the cells in culture convert greater than or about 0.002, 0.005, 0.01, 0.02, 0.05, 0.1, 0.12, 0.14, 0.16, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0, 1.2, 1.4, 1.6%, or more of the carbon in the cell culture medium into isoprene. In some embodiments of any of the aspects of the invention, the cells in culture produce isoprene at greater than or about 1, 10, 25, 50, 100, 150, 200, 250, 300, 400, 500, 600, 700, 800, 900, 1,000, 1,250, 1,500, 1,750, 2,000, 2,500, 3,000, 4,000, 5,000, 10,000,

100,000, or more ng of isoprene/gram of cells for the wet weight of the cells /hr (ng/g_{wcm}/h). In some embodiments of any of the aspects of the invention, the cells in culture produce a cumulative titer (total amount) of isoprene at greater than or about 1, 10, 25, 50, 100, 150, 200, 250, 300, 400, 500, 600, 700, 800, 900, 1,000, 1,250, 1,500, 1,750, 2,000, 2,500, 3,000, 4,000, 5,000, 10,000, 50,000, 100,000, or more mg of isoprene/L of broth (mg/L_{broth}, wherein the volume of broth includes the volume of the cells and the cell medium). Other exemplary rates of isoprene production and total amounts of isoprene production are disclosed herein.

[038] In some embodiments of any of the aspects of the invention, the cells further comprise a heterologous nucleic acid encoding an isopentenyl-diphosphate delta-isomerase (IDI) polypeptide. In some embodiments of any of the aspects of the invention, the cells further comprise an insertion of a copy of an endogenous nucleic acid encoding an IDI polypeptide. In some embodiments of any of the aspects of the invention, the cells further comprise a heterologous nucleic acid encoding a 1-Deoxyxylulose-5-phosphate synthase (DXS) polypeptide. In some embodiments of any of the aspects of the invention, the cells further comprise an insertion of a copy of an endogenous nucleic acid encoding a DXS polypeptide. In some embodiments of any of the aspects of the invention, the cells further comprise one or more nucleic acids encoding an IDI polypeptide and a DXS polypeptide. In some embodiments of any of the aspects of the invention, one nucleic acid encodes the isoprene synthase polypeptide, IDI polypeptide, and DXS polypeptide. In some embodiments of any of the aspects of the invention, one vector encodes the isoprene synthase polypeptide, IDI polypeptide, and DXS polypeptide. In some embodiments, the vector comprises a selective marker, such as an antibiotic resistance nucleic acid.

[039] In some embodiments of any of the aspects of the invention, the heterologous isoprene synthase nucleic acid and/or the heterologous efe nucleic acid is operably linked to a T7 promoter, such as a T7 promoter contained in a medium or high copy plasmid. In some embodiments of any of the aspects of the invention, the heterologous isoprene synthase nucleic acid or the heterologous efe nucleic acid is operably linked to a Trc promoter, such as a Trc promoter contained in a medium or high copy plasmid. In some embodiments of any of the aspects of the invention, the heterologous isoprene synthase nucleic acid or the heterologous efe nucleic acid is operably linked to a Lac promoter, such as a Lac promoter contained in a low copy plasmid. In some embodiments of any of the

aspects of the invention, the heterologous isoprene synthase nucleic acid or the heterologous efe nucleic acid is operably linked to an endogenous promoter, such as an endogenous alkaline serine protease promoter. In some embodiments, the heterologous isoprene synthase nucleic acid or the heterologous efe nucleic acid integrates into a chromosome of the cells without a selective marker.

[040] In some embodiments, one or more MVA pathway, IDI, DXP pathway, efe or isoprene synthase nucleic acids are placed under the control of a promoter or factor that is more active in stationary phase than in the growth phase. For example, one or more MVA pathway, IDI, DXP pathway, efe or isoprene synthase nucleic acids may be placed under control of a stationary phase sigma factor, such as RpoS. In some embodiments, one or more MVA pathway, IDI, DXP pathway, efe or isoprene synthase nucleic acids are placed under control of a promoter inducible in stationary phase, such as a promoter inducible by a response regulator active in stationary phase.

[041] In some embodiments of any of the aspects of the invention, at least a portion of the cells maintain the heterologous isoprene synthase nucleic acid or efe nucleic acid for at least or about 5, 10, 20, 40, 50, 60, 65, or more cell divisions in a continuous culture (such as a continuous culture without dilution). In some embodiments of any of the aspects of the invention, the nucleic acid comprising the isoprene synthase, efe, IDI, or DXS nucleic acid also comprises a selective marker, such as an antibiotic resistance nucleic acid.

[042] In some embodiments of any of the aspects of the invention, the cells further comprise a heterologous nucleic acid encoding an MVA pathway polypeptide (such as an MVA pathway polypeptide from *Saccharomyces cerevisiae* or *Enterococcus faecalis*). In one embodiment, MVA pathway polypeptide is mevalonate kinase. In some embodiments of any of the aspects of the invention, the cells further comprise an insertion of a copy of an endogenous nucleic acid encoding an MVA pathway polypeptide (such as an MVA pathway polypeptide from *Saccharomyces cerevisiae* or *Enterococcus faecalis*). In some embodiments of any of the aspects of the invention, the cells comprise an isoprene synthase, DXS, and MVA pathway nucleic acid. In some embodiments of any of the aspects of the invention, the cells comprise an isoprene synthase nucleic acid, a DXS nucleic acid, an IDI nucleic acid, and a MVA pathway nucleic (in addition to the IDI nucleic acid).

[043] In some embodiments of any of the aspects of the invention, the isoprene synthase polypeptide is a polypeptide from a plant such as *Pueraria* (e.g., *Pueraria montana* or *Pueraria lobata*) or *Populus* (e.g., *Populus tremuloides*, *Populus alba*, *Populus nigra*, *Populus trichocarpa*, or the hybrid, *Populus alba* x *Populus tremula*). In some embodiments of any of the aspects of the invention, the efe is a polypeptide from a bacteria such as *Pseudomonas* (e.g., *Pseudomonas syringae*).

[044] In some embodiments of any of the aspects of the invention, the cells are bacterial cells, such as gram-positive bacterial cells (e.g., *Bacillus* cells such as *Bacillus subtilis* cells or *Streptomyces* cells such as *Streptomyces lividans*, *Streptomyces coelicolor*, or *Streptomyces griseus* cells). In some embodiments of any of the aspects of the invention, the cells are gram-negative bacterial cells (e.g., *Escherichia* cells such as *Escherichia coli* cells, *Rhodopseudomonas* sp. such as *Rhodopseudomonas palustris* cells, *Pseudomonas* sp. such as *Pseudomonas fluorescens* cells or *Pseudomonas putida* cells, or *Pantoea* cells such as *Pantoea citrea* cells). In some embodiments of any of the aspects of the invention, the cells are fungal, cells such as filamentous fungal cells (e.g., *Trichoderma* cells such as *Trichoderma reesei* cells or *Aspergillus* cells such as *Aspergillus oryzae* and *Aspergillus niger*) or yeast cells (e.g., *Yarrowia* cells such as *Yarrowia lipolytica* cells or *Saccharomyces* cells such as *Saccharomyces cerevisiae*).

[045] In some embodiments of any of the aspects of the invention, the microbial polypeptide carbon source includes one or more polypeptides from yeast or bacteria. In some embodiments of any of the aspects of the invention, the plant polypeptide carbon source includes one or more polypeptides from soy, corn, canola, jatropha, palm, peanut, sunflower, coconut, mustard, rapeseed, cottonseed, palm kernel, olive, safflower, sesame, or linseed.

[046] In one aspect, the invention features a product produced by any of the compositions or methods of the invention. It is to be understood that one, some, or all of the properties of the various embodiments described herein may be combined to form other embodiments of the present invention. The headings provided herein are not limitations of the various aspects or embodiments of the invention which can be had by reference to the specification as a whole.

BRIEF DESCRIPTION OF THE DRAWINGS

- [047] Figure 1 is the nucleotide sequence of a kudzu isoprene synthase gene codon-optimized for expression in *E. coli* (SEQ ID NO:1). The atg start codon is in italics, the stop codon is in bold and the added *Pst*I site is underlined.
- [048] Figure 2 is a map of pTrcKudzu.
- [049] Figures 3A-C are the nucleotide sequence of pTrcKudzu (SEQ ID NO:2). The RBS is underlined, the kudzu isoprene synthase start codon is in bold capital letters and the stop codon is in bold, capital, italics letters. The vector backbone is pTrcHis2B.
- [050] Figure 4 is a map of pETNHisKudzu.
- [051] Figures 5A-C are the nucleotide sequence of pETNHisKudzu (SEQ ID NO:5).
- [052] Figure 6 is a map of pCL-lac-Kudzu.
- [053] Figures 7A-C are the nucleotide sequence of pCL-lac-Kudzu (SEQ ID NO:7).
- [054] Figure 8A is a graph showing the production of isoprene in *E. coli* BL21 cells with no vector.
- [055] Figure 8B is a graph showing the production of isoprene in *E. coli* BL21 cells with pCL-lac-Kudzu
- [056] Figure 8C is a graph showing the production of isoprene in *E. coli* BL21 cells with pTrcKudzu.
- [057] Figure 8D is a graph showing the production of isoprene in *E. coli* BL21 cells with pETN-HisKudzu.
- [058] Figure 9A is a graph showing OD over time of fermentation of *E. coli* BL21/pTrcKudzu in a 14 liter fed batch fermentation.
- [059] Figure 9B is a graph showing isoprene production over time of fermentation of *E. coli* BL21/pTrcKudzu in a 14 liter fed batch fermentation.

[060] Figure 10A is a graph showing the production of isoprene in *Pantoea citrea*. Control cells without recombinant kudzu isoprene synthase. Grey diamonds represent isoprene synthesis, black squares represent OD₆₀₀.

[061] Figure 10B is a graph showing the production of isoprene in *Pantoea citrea* expressing pCL-lac Kudzu. Grey diamonds represent isoprene synthesis, black squares represent OD₆₀₀.

[062] Figure 10C is a graph showing the production of isoprene in *Pantoea citrea* expressing pTrcKudzu. Grey diamonds represent isoprene synthesis, black squares represent OD₆₀₀.

[063] Figure 11 is a graph showing the production of isoprene in *Bacillus subtilis* expressing recombinant isoprene synthase. BG3594comK is a *B. subtilis* strain without plasmid (native isoprene production). CF443-BG3594comK is a *B. subtilis* strain with pBSKudzu (recombinant isoprene production). IS on the y-axis indicates isoprene.

[064] Figures 12A-C are the nucleotide sequence of pBS Kudzu #2 (SEQ ID NO:57).

[065] Figure 13 is the nucleotide sequence of kudzu isoprene synthase codon-optimized for expression in *Yarrowia* (SEQ ID NO:8).

[066] Figure 14 is a map of pTrex3g comprising a kudzu isoprene synthase gene codon-optimized for expression in *Yarrowia*.

[067] Figures 15A-C are the nucleotide sequence of vector pSPZ1(MAP29S_{pb}) (SEQ ID NO:11).

[068] Figure 16 is the nucleotide sequence of the synthetic kudzu (*Pueraria montana*) isoprene gene codon-optimized for expression in *Yarrowia* (SEQ ID NO:12).

[069] Figure 17 is the nucleotide sequence of the synthetic hybrid poplar (*Populus alba* x *Populus tremula*) isoprene synthase gene (SEQ ID NO:13). The ATG start codon is in bold and the stop codon is underlined.

[070] Figure 18A shows a schematic outlining construction of vectors pYLA 1, pYL1 and pYL2 (SEQ ID NO:79, 77, 76, 75, 74, and 73).

[071] Figure 18B shows a schematic outlining construction of the vector pYLA(POP1) (SEQ ID NO:72 and 73).

[072] Figure 18C shows a schematic outlining construction of the vector pYLA(KZ1) (SEQ ID NO:70 and 71).

[073] Figure 18D shows a schematic outlining construction of the vector pYLI(KZ1).

[074] Figure 18E shows a schematic outlining construction of the vector pYLI(MAP29).

[075] Figure 18F shows a schematic outlining construction of the vector pYLA(MAP29).

[076] Figure 19A shows the MVA and DXP metabolic pathways for isoprene (based on F. Bouvier *et al.*, Progress in Lipid Res. 44: 357-429, 2005). The following description includes alternative names for each polypeptide in the pathways and a reference that discloses an assay for measuring the activity of the indicated polypeptide (each of these references are each hereby incorporated by reference in their entireties, particularly with respect to assays for polypeptide activity for polypeptides in the MVA and DXP pathways). **Mevalonate Pathway:** **AACT**; Acetyl-CoA acetyltransferase, MvaE, EC 2.3.1.9. Assay: J. Bacteriol., 184: 2116–2122, 2002; **HMGS**; Hydroxymethylglutaryl-CoA synthase, MvaS, EC 2.3.3.10. Assay: J. Bacteriol., 184: 4065–4070, 2002; **HMGR**; 3-Hydroxy-3-methylglutaryl-CoA reductase, MvaE, EC 1.1.1.34. Assay: J. Bacteriol., 184: 2116–2122, 2002; **MVK**; Mevalonate kinase, ERG12, EC 2.7.1.36. Assay: Curr Genet 19:9-14, 1991. **PMK**; Phosphomevalonate kinase, ERG8, EC 2.7.4.2, Assay: Mol Cell Biol., 11:620–631, 1991; **DPMDC**; Diphosphomevalonate decarboxylase, MVD1, EC 4.1.1.33. Assay: Biochemistry, 33:13355-13362, 1994; **IDI**; Isopentenyl-diphosphate delta-isomerase, IDI1, EC 5.3.3.2. Assay: J. Biol. Chem. 264:19169-19175, 1989. **DXP Pathway:** **DXS**; 1-Deoxyxylulose-5-phosphate synthase, dxs, EC 2.2.1.7. Assay: PNAS, 94:12857-62, 1997; **DXR**; 1-Deoxy-D-xylulose 5-phosphate reductoisomerase, dxr, EC 2.2.1.7. Assay: Eur. J. Biochem. 269:4446–4457, 2002; **MCT**; 4-Diphosphocytidyl-2C-methyl-D-erythritol synthase, IspD, EC 2.7.7.60. Assay: PNAS, 97: 6451–6456, 2000; **CMK**; 4-Diphosphocytidyl-2-C-methyl-D-erythritol kinase, IspE, EC 2.7.1.148. Assay: PNAS, 97:1062-1067, 2000; **MCS**; 2C-Methyl-D-erythritol 2,4-cyclodiphosphate synthase, IspF, EC 4.6.1.12. Assay: PNAS, 96:11758-11763, 1999; **HDS**; 1-Hydroxy-2-methyl-2-(E)-butenyl 4-diphosphate synthase, ispG, EC 1.17.4.3. Assay: J. Org. Chem.,

70:9168 -9174, 2005; **HDR**; 1-Hydroxy-2-methyl-2-(E)-butenyl 4-diphosphate reductase, IspH, EC 1.17.1.2. Assay: JACS, 126:12847-12855, 2004.

[077] Figure 19B illustrates the classical and modified MVA pathways. 1, acetyl-CoA acetyltransferase (**AACT**); 2, HMG-CoA synthase (**HMGs**); 3, HMG-CoA reductase (**HMGR**); 4, mevalonate kinase (**MVK**); 5, phosphomevalonate kinase (**PMK**); 6, diphosphomevalonate decarboxylase (**MVD or DPMDC**); 7, isopentenyl diphosphate isomerase (**IDI**); 8, phosphomevalonate decarboxylase (**PMDC**); 9, isopentenyl phosphate kinase (**IPK**). The classical MVA pathway proceeds from reaction 1 through reaction 7 via reactions 5 and 6, while a modified MVA pathway goes through reactions 8 and 9. P and PP in the structural formula are phosphate and pyrophosphate, respectively. This figure was taken from Koga and Morii, *Microbiology and Mol. Biology Reviews*, 71:97-120, 2007, which is incorporated by reference in its entirety, particular with respect to nucleic acids and polypeptides of the modified MVA pathway. The modified MVA pathway is present, for example, in some archaeal organisms, such as *Methanosarcina mazei*.

[078] Figure 20 shows graphs representing results of the GC-MS analysis of isoprene production by recombinant *Y. lipolytica* strains without (left) or with (right) a kudzu isoprene synthase gene. The arrows indicate the elution time of the authentic isoprene standard.

[079] Figure 21 is a map of pTrcKudzu yIDI DXS Kan.

[080] Figures 22A-D are the nucleotide sequence of pTrcKudzu yIDI DXS Kan (SEQ ID NO:20).

[081] Figure 23A is a graph showing production of isoprene from glucose in BL21/pTrcKudzukan. Time 0 is the time of induction with IPTG (400 μ mol). The x-axis is time after induction; the y-axis is OD₆₀₀ and the y2-axis is total productivity of isoprene (μ g/L headspace or specific productivity (μ g/L headspace/OD)). Diamonds represent OD₆₀₀, circles represent total isoprene productivity (μ g/L) and squares represent specific productivity of isoprene (μ g/L/OD).

[082] Figure 23B is a graph showing production of isoprene from glucose in BL21/pTrcKudzu yIDI kan. Time 0 is the time of induction with IPTG (400 μ mol). The x-axis is time after induction; the y-axis is OD₆₀₀ and the y2-axis is total productivity of

isoprene ($\mu\text{g/L}$ headspace or specific productivity ($\mu\text{g/L headspace/OD}$)). Diamonds represent OD_{600} , circles represent total isoprene productivity ($\mu\text{g/L}$) and squares represent specific productivity of isoprene ($\mu\text{g/L/OD}$).

[083] Figure 23C is a graph showing production of isoprene from glucose in BL21/pTrcKudzu DXS kan. Time 0 is the time of induction with IPTG (400 μmol). The x-axis is time after induction; the y-axis is OD_{600} and the y2-axis is total productivity of isoprene ($\mu\text{g/L headspace or specific productivity } (\mu\text{g/L headspace/OD})$). Diamonds represent OD_{600} , circles represent total isoprene productivity ($\mu\text{g/L}$) and squares represent specific productivity of isoprene ($\mu\text{g/L/OD}$).

[084] Figure 23D is a graph showing production of isoprene from glucose in BL21/pTrcKudzu yIDI DXS kan. Time 0 is the time of induction with IPTG (400 μmol). The x-axis is time after induction; the y-axis is OD_{600} and the y2-axis is total productivity of isoprene ($\mu\text{g/L headspace or specific productivity } (\mu\text{g/L headspace/OD})$). Diamonds represent OD_{600} , circles represent total isoprene productivity ($\mu\text{g/L}$) and squares represent specific productivity of isoprene ($\mu\text{g/L/OD}$).

[085] Figure 23E is a graph showing production of isoprene from glucose in BL21/pCL PtrcKudzu. Time 0 is the time of induction with IPTG (400 μmol). The x-axis is time after induction; the y-axis is OD_{600} and the y2-axis is total productivity of isoprene ($\mu\text{g/L headspace or specific productivity } (\mu\text{g/L headspace/OD})$). Diamonds represent OD_{600} , circles represent total isoprene productivity ($\mu\text{g/L}$) and squares represent specific productivity of isoprene ($\mu\text{g/L/OD}$).

[086] Figure 23F is a graph showing production of isoprene from glucose in BL21/pCL PtrcKudzu yIDI. Time 0 is the time of induction with IPTG (400 μmol). The x-axis is time after induction; the y-axis is OD_{600} and the y2-axis is total productivity of isoprene ($\mu\text{g/L headspace or specific productivity } (\mu\text{g/L headspace/OD})$). Diamonds represent OD_{600} , circles represent total isoprene productivity ($\mu\text{g/L}$) and squares represent specific productivity of isoprene ($\mu\text{g/L/OD}$).

[087] Figure 23G is a graph showing production of isoprene from glucose in BL21/pCL PtrcKudzu DXS. Time 0 is the time of induction with IPTG (400 μmol). The x-axis is time after induction; the y-axis is OD_{600} and the y2-axis is total productivity of isoprene ($\mu\text{g/L headspace or specific productivity } (\mu\text{g/L headspace/OD})$). Diamonds represent OD_{600} ,

circles represent total isoprene productivity ($\mu\text{g/L}$) and squares represent specific productivity of isoprene ($\mu\text{g/L/OD}$).

[088] Figure 23H is a graph showing production of isoprene from glucose in BL21/pTrcKudzuIDIDXkan. The arrow indicates the time of induction with IPTG (400 μmol). The x-axis is time after inoculation; the y-axis is OD600 and the y2-axis is total productivity of isoprene ($\mu\text{g/L}$ headspace or specific productivity ($\mu\text{g/L}$ headspace/OD)). Diamonds represent OD600, triangles represent total isoprene productivity ($\mu\text{g/L}$) and squares represent specific productivity of isoprene ($\mu\text{g/L/OD}$).

[089] Figure 24 is a map of pTrcKKDyIkIS kan.

[090] Figures 25A-D are a nucleotide sequence of pTrcKKDyIkIS kan (SEQ ID NO:33).

[091] Figure 26 is a map of pCL PtrcUpperPathway.

[092] Figures 27A-27D is a nucleotide sequence of pCL PtrcUpperPathway (SEQ ID NO:46).

[093] Figure 28 shows a map of the cassette containing the lower MVA pathway and yeast IDI for integration into the *B. subtilis* chromosome at the *nprE* locus. *nprE* upstream/downstream indicates 1 kb each of sequence from the *nprE* locus for integration. *aprE* promoter (alkaline serine protease promoter) indicates the promoter (-35, -10, +1 transcription start site, RBS) of the *aprE* gene. MVK1 indicates the yeast mevalonate kinase gene. RBS-PMK indicates the yeast phosphomevalonate kinase gene with a *Bacillus* RBS upstream of the start site. RBS-MPD indicates the yeast diphosphomevalonate decarboxylase gene with a *Bacillus* RBS upstream of the start site. RBS-IDI indicates the yeast IDI gene with a *Bacillus* RBS upstream of the start site. Terminator indicates the terminator alkaline serine protease transcription terminator from *B. amyliquefaciens*. SpecR indicates the spectinomycin resistance marker. “*nprE* upstream repeat for amp.” indicates a direct repeat of the upstream region used for amplification.

[094] Figures 29A-D are a nucleotide sequence of cassette containing the lower MVA pathway and yeast IDI for integration into the *B. subtilis* chromosome at the *nprE* locus (SEQ ID NO:47).

[095] Figure 30 is a map of p9796-poplar.

- [096] Figures 31A and B are a nucleotide sequence of p9796-poplar (SEQ ID NO:48).
- [097] Figure 32 is a map of pTrcPoplar.
- [098] Figures 33A-C are a nucleotide sequence of pTrcPoplar (SEQ ID NO:49).
- [099] Figure 34 is a map of pTrcKudzu yIDI Kan.
- [0100] Figures 35A-C are a nucleotide sequence of pTrcKudzu yIDI Kan (SEQ ID NO:50).
- [0101] Figure 36 is a map of pTrcKudzuDXS Kan.
- [0102] Figures 37A-C are a nucleotide sequence of pTrcKudzuDXS Kan (SEQ ID NO:51).
- [0103] Figure 38 is a map of pCL PtrcKudzu.
- [0104] Figures 39A-C are a nucleotide sequence of pCL PtrcKudzu (SEQ ID NO:52).

- [0109] Figure 44 is a map of pCL PtrcKudzu DXS.
- [0110] Figures 45A-D are a nucleotide sequence of pCL PtrcKudzu DXS (SEQ ID NO:55).
- [0111] Figures 46A-E show graphs representing isoprene production from biomass feedstocks. Panel A shows isoprene production from corn stover, Panel B shows isoprene production from bagasse, Panel C shows isoprene production from softwood pulp, Panel D shows isoprene production from glucose, and Panel E shows isoprene production from cells with no additional feedstock. Grey squares represent OD₆₀₀ measurements of the cultures at the indicated times post-inoculation and black triangles represent isoprene production at the indicated times post-inoculation.

[0112] Figure 47A shows a graph representing isoprene production by BL21 (λ DE3) pTrcKudzu yIDI DXS (kan) in a culture with no glucose added. Squares represent OD₆₀₀, and triangles represent isoprene produced (μ g/ml).

[0113] Figure 47B shows a graph representing isoprene production from 1% glucose feedstock invert sugar by BL21 (λ DE3) pTrcKudzu yIDI DXS (kan). Squares represent OD₆₀₀, and triangles represent isoprene produced (μ g/ml).

[0114] Figure 47C shows a graph representing isoprene production from 1% invert sugar feedstock by BL21 (λ DE3) pTrcKudzu yIDI DXS (kan). Squares represent OD₆₀₀, and triangles represent isoprene produced (μ g/ml).

[0115] Figure 47D shows a graph representing isoprene production from 1% AFEX corn stover feedstock by BL21 (λ DE3) pTrcKudzu yIDI DXS (kan). Squares represent OD₆₀₀, and triangles represent isoprene produced (μ g/ml).

[0116] Figures 48A-C show graphs demonstrating the effect of yeast extract of isoprene production. Panel A shows the time course of optical density within fermentors fed with varying amounts of yeast extract. Panel B shows the time course of isoprene titer within fermentors fed with varying amounts of yeast extract. The titer is defined as the amount of isoprene produced per liter of fermentation broth. Panel C shows the effect of yeast extract on isoprene production in *E. coli* grown in fed-batch culture.

[0117] Figures 49A-C show graphs demonstrating isoprene production from a 500 L bioreactor with *E. coli* cells containing the pTrcKudzu + yIDI + DXS plasmid. Panel A shows the time course of optical density within the 500-L bioreactor fed with glucose and yeast extract. Panel B shows the time course of isoprene titer within the 500-L bioreactor fed with glucose and yeast extract. The titer is defined as the amount of isoprene produced per liter of fermentation broth. Panel C shows the time course of total isoprene produced from the 500-L bioreactor fed with glucose and yeast extract.

[0118] Figure 50 is a map of pJMupperpathway2.

[0119] Figures 51A-C are the nucleotide sequence of pJMupperpathway2 (SEQ ID NO:56).

[0120] Figure 52 is a map of pBS Kudzu #2.

[0121] Figure 53A is a graph showing growth during fermentation time of *Bacillus* expressing recombinant kudzu isoprene synthase in 14 liter fed batch fermentation. Black diamonds represent a control strain (BG3594comK) without recombinant isoprene synthase (native isoprene production) and grey triangles represent *Bacillus* with pBSKudzu (recombinant isoprene production).

[0122] Figure 53B is a graph showing isoprene production during fermentation time of *Bacillus* expressing recombinant kudzu isoprene synthase in 14 liter fed batch fermentation. Black diamonds represent a control strain (BG3594comK) without recombinant isoprene synthase (native isoprene production) and grey triangles represent *Bacillus* with pBSKudzu (recombinant isoprene production).

[0123] Figure 54 is a time course of optical density within the 15-L bioreactor fed with glucose.

[0124] Figure 55 is a time course of isoprene titer within the 15-L bioreactor fed with glucose. The titer is defined as the amount of isoprene produced per liter of fermentation broth.

[0125] Figure 56 is a time course of total isoprene produced from the 15-L bioreactor fed with glucose.

[0126] Figure 57 is a time course of optical density within the 15-L bioreactor fed with glycerol.

[0127] Figure 58 is a time course of isoprene titer within the 15-L bioreactor fed with glycerol. The titer is defined as the amount of isoprene produced per liter of fermentation broth.

[0128] Figure 59 is a time course of total isoprene produced from the 15-L bioreactor fed with glycerol.

[0129] Figures 60A-60C are the time courses of optical density, mevalonic acid titer, and specific productivity within the 150-L bioreactor fed with glucose.

[0130] Figures 61A-61C are the time courses of optical density, mevalonic acid titer, and specific productivity within the 15-L bioreactor fed with glucose.

[0131] Figures 62A-62C are the time courses of optical density, mevalonic acid titer, and specific productivity within the 15-L bioreactor fed with glucose.

[0132] Figure 63A-63C are the time courses of optical density, isoprene titer, and specific productivity within the 15-L bioreactor fed with glucose.

[0133] Figures 64A-64C are the time courses of optical density, isoprene titer, and specific productivity within the 15-L bioreactor fed with glucose.

[0134] Figures 65A-65C are the time courses of optical density, isoprene titer, and specific productivity within the 15-L bioreactor fed with glucose.

[0135] Figures 66A-66C are the time courses of optical density, isoprene titer, and specific productivity within the 15-L bioreactor fed with glucose.

[0136] Figure 67A-67C are the time courses of optical density, isoprene titer, and specific productivity within the 15-L bioreactor fed with glucose.

[0137] Figure 68 is a graph of the calculated adiabatic flame temperatures for Series A as a function of fuel concentration for various oxygen levels. The figure legend lists the curves in the order in which they appear in the graph. For example, the first entry in the figure legend (isoprene in air at 40 °C) corresponds to the highest curve in the graph.

[0138] Figure 69 is a graph of the calculated adiabatic flame temperatures for Series B as a function of fuel concentration for various oxygen levels with 4% water. The figure legend lists the curves in the order in which they appear in the graph.

[0139] Figure 70 is a graph of the calculated adiabatic flame temperatures for Series C as a function of fuel concentration for various oxygen levels with 5% CO₂. The figure legend lists the curves in the order in which they appear in the graph.

[0140] Figure 71 is a graph of the calculated adiabatic flame temperatures for Series D as a function of fuel concentration for various oxygen levels with 10% CO₂. The figure legend lists the curves in the order in which they appear in the graph.

[0141] Figure 72 is a graph of the calculated adiabatic flame temperatures for Series E as a function of fuel concentration for various oxygen levels with 15% CO₂. The figure legend lists the curves in the order in which they appear in the graph.

[0142] Figure 73 is a graph of the calculated adiabatic flame temperatures for Series F as a function of fuel concentration for various oxygen levels with 20% CO₂. The figure legend lists the curves in the order in which they appear in the graph.

[0143] Figure 74 is a graph of the calculated adiabatic flame temperatures for Series G as a function of fuel concentration for various oxygen levels with 30% CO₂. The figure legend lists the curves in the order in which they appear in the graph.

[0144] Figure 75A is a table of the conversion of the CAFT Model results from weight percent to volume percent for series A.

[0145] Figure 75B is a graph of the flammability results from the CAFT model for Series A in Figure 68 plotted as volume percent.

[0146] Figure 76A is a table of the conversion of the CAFT Model results from weight percent to volume percent for series B.

[0147] Figure 76B is a graph of the flammability results from the CAFT model for Series B in Figure 69 plotted as volume percent.

[0173] Figure 94 is a time course of isoprene titer within the 15-L bioreactor fed with glucose. The titer is defined as the amount of isoprene produced per liter of fermentation broth.

[0174] Figure 95 is a time course of total isoprene produced from the 15-L bioreactor fed with glucose.

[0175] Figure 96 is a time course of optical density within the 15-L bioreactor fed with invert sugar.

[0176] Figure 97 is a time course of isoprene titer within the 15-L bioreactor fed with invert sugar. The titer is defined as the amount of isoprene produced per liter of fermentation broth.

[0177] Figure 98 is a time course of total isoprene produced from the 15-L bioreactor fed with invert sugar.

[0178] Figure 99 is a time course of optical density within the 15-L bioreactor fed with glucose.

[0179] Figure 100 is a time course of isoprene titer within the 15-L bioreactor fed with glucose. The titer is defined as the amount of isoprene produced per liter of fermentation broth.

[0180] Figure 101 is a time course of isoprene specific activity from the 15-L bioreactor fed with glucose.

[0181] Figure 102 is a map of pCLPtrcUpperPathwayHGS2.

[0182] Figures 103A-103C are the nucleotide sequence of pCLPtrcUpperPathwayHGS2 (SEQ ID NO:87).

[0183] Figure 104 is a time course of optical density within the 15-L bioreactor fed with glucose.

[0184] Figure 105 is a time course of isoprene titer within the 15-L bioreactor fed with glucose. The titer is defined as the amount of isoprene produced per liter of fermentation broth.

[0185] Figure 106 is a time course of total isoprene produced from the 15-L bioreactor fed with glucose.

[0186] Figure 107 is a map of plasmid MCM330.

[0187] Figures 108A-108C are the nucleotide sequence of plasmid MCM330 (SEQ ID NO:90).

[0188] Figure 109 is a map of pET24D-Kudzu.

[0189] Figures 110A and 110B are the nucleotide sequence of pET24D-Kudzu (SEQ ID NO:101).

[0190] Figure 111A is a time course of optical density within the 15-L bioreactor fed with glucose.

[0191] Figure 111B is a time course of isoprene titer within the 15-L bioreactor fed with glucose. The titer is defined as the amount of isoprene produced per liter of fermentation broth.

[0192] Figure 111C is a time course of specific productivity of isoprene in the 15-L bioreactor fed with glucose.

[0193] Figure 112A is a map of the *M. mazei* archeal Lower Pathway operon.

[0194] Figures 112B and 112C are the nucleotide sequence of the *M. mazei* archeal lower Pathway operon (SEQ ID NO:102).

[0195] Figure 113A is a map of MCM382 – pTrcKudzuMVK(mazei).

[0196] Figures 113B and 113C are the nucleotide sequence of MCM382 – pTrcKudzuMVK(mazei) (SEQ ID NO:103).

[0197] Figure 114A is a map of MCM376 - MVK from *M. mazei* archeal Lower in pET200D.

[0198] Figures 114B and 114C are the nucleotide sequence of MCM376 - MVK from *M. mazei* archeal Lower in pET200D (SEQ ID NO:108).

[0199] Figures 115A-115D demonstrate that over-expression of MVK and isoprene synthase results in increased isoprene production. Accumulated isoprene and CO₂ from MCM401 and MCM343 during growth on glucose in 100 mL bioreactors with 100 and 200 uM IPTG induction of isoprene production was measured over a 22 hour time course. Figure 115A is a graph of the accumulated isoprene (%) from MCM343. Figure 115B is a graph of the accumulated isoprene (%) from MCM401. Figure 115C is a graph of the accumulated CO₂ (%) from MCM343. Figure 115D is a graph of the accumulated CO₂ (%) from MCM401.

[0200] Figure 116 is a time course of optical density within the 15-L bioreactor fed with glucose.

[0201] Figure 117 is a time course of isoprene titer within the 15-L bioreactor fed with glucose. The titer is defined as the amount of isoprene produced per liter of fermentation broth.

[0202] Figure 118 is a time course of total isoprene produced from the 15-L bioreactor fed with glucose.

[0203] Figure 119 is a graph of the total carbon dioxide evolution rate (TCER), or metabolic activity profile, within the 15-L bioreactor fed with glucose.

[0204] Figure 120 is a graph of the cell viability during isoprene production within the 15-L bioreactor fed with glucose. TVC/OD is the total viable counts (colony forming units) in 1 mL of broth per optical density unit (OD₅₅₀).

[0205] Figure 121 is a time course of optical density within the 15-L bioreactor fed with glucose.

[0206] Figure 122 is a time course of isoprene titer within the 15-L bioreactor fed with glucose. The titer is defined as the amount of isoprene produced per liter of fermentation broth.

[0207] Figure 123 is a time course of total isoprene produced from the 15-L bioreactor fed with glucose.

[0208] Figure 124 is a time course of volumetric productivity within the 15-L bioreactor fed with glucose. The volumetric productivity is defined as the amount of isoprene produced per liter of broth per hour.

[0209] Figure 125 is a time course of instantaneous yield within the 15-L bioreactor fed with glucose. The instantaneous yield is defined as the amount of isoprene (gram) produced per amount of glucose (gram) fed to the bioreactor (w/w) during the time interval between the data points.

[0210] Figure 126 is a graph of the total carbon dioxide evolution rate (TCER), or metabolic activity profile, within the 15-L bioreactor fed with glucose.

[0211] Figure 127 is cell viability during isoprene production within the 15-L bioreactor fed with glucose. TVC/OD is the total viable counts (colony forming units) in 1 mL of broth per optical density unit (OD₅₅₀).

[0212] Figure 128 is a time course of optical density within the 15-L bioreactor fed with glucose.

[0213] Figure 129 is a time course of isoprene titer within the 15-L bioreactor fed with glucose. The titer is defined as the amount of isoprene produced per liter of fermentation broth.

[0214] Figure 130 is a time course of total isoprene produced from the 15-L bioreactor fed with glucose.

[0215] Figure 131 is a graph of total carbon dioxide evolution rate (TCER), or metabolic activity profile, within the 15-L bioreactor fed with glucose.

[0216] Figure 132 is a graph showing that a transient decrease in the airflow to the bioreactor caused a spike in the concentration of isoprene in the offgas that did not cause a dramatic decrease in metabolic activity (TCER). TCER, or metabolic activity, is the total carbon dioxide evolution rate.

[0217] Figure 133 is a graph of the cell viability during isoprene production within the 15-L bioreactor fed with glucose. TVC/OD is the total viable counts (colony forming units) in 1 mL of broth per optical density unit (OD₅₅₀).

[0218] Figure 134 is a time course of optical density within the 15-L bioreactor fed with glucose. Dotted vertical lines denote the time interval when isoprene was introduced into the bioreactor at a rate of 1 g/L/hr.

[0219] Figure 135 is total carbon dioxide evolution rate (TCER), or metabolic activity profile, within the 15-L bioreactor fed with glucose. Dotted vertical lines denote the time interval when isoprene was introduced into the bioreactor at a rate of 1 g/L/hr.

[0220] Figure 136 is cell viability during isoprene production within the 15-L bioreactor fed with glucose. TVC/OD is the total viable counts (colony forming units) in 1 mL of broth per optical density unit (OD₅₅₀). Dotted vertical lines denote the time interval when isoprene was introduced into the bioreactor at a rate of 1 g/L/hr.

DETAILED DESCRIPTION OF THE INVENTION

[0254] The invention provides for, *inter alia*, compositions and methods for producing a compound having one or both of the following characteristics: (a) a Henry's law coefficient of less than about 250 M/atm and/or (b) a solubility in water of less than about 100 g/L. In one embodiment, the compound is isoprene. In another embodiment, the compound is ethylene. The invention features methods of producing isoprene by culturing cells under conditions suitable for isoprene production while maintaining cell viability and/or metabolic activity as indicated by carbon dioxide evolution rate or total carbon dioxide evolution rate. Carbon dioxide evolution rate (CER) and total carbon dioxide evolution rate (total CER) are terms well-known to one of skill in the art of fermentation and commonly refers to the carbon dioxide evolved by the culture (e.g., mmol/L/hr).

[0255] Further, in some aspects, the invention features methods of producing isoprene by culturing cells under suitable conditions for production of isoprene with concentrated isoprene in the gas phase using reduced gas sparging rates or no gas sparging. In some aspects, the invention also features methods of producing a compound with a Henry's law coefficient of less than about 250 M/atm and/or low water solubility (high water insolubility). In some aspects, the invention also features method of producing ethylene.

[0256] Unless defined otherwise, the meanings of all technical and scientific terms used herein are those commonly understood by one of skill in the art to which this invention belongs. Singleton, *et al.*, Dictionary of Microbiology and Molecular Biology, 2nd ed., John Wiley and Sons, New York (1994), and Hale & Marham, The Harper Collins Dictionary of Biology, Harper Perennial, N.Y. (1991) provide one of skill with a general dictionary of many of the terms used in this invention. It is to be understood that this invention is not limited to the particular methodology, protocols, and reagents described, as these may vary. One of skill in the art will also appreciate that any methods and materials similar or equivalent to those described herein can also be used to practice or test the invention.

[0257] For use herein, unless clearly indicated otherwise, use of the terms “a”, “an,” and the like refers to one or more.

[0258] Reference to “about” a value or parameter herein includes (and describes) embodiments that are directed to that value or parameter per se. For example, description referring to “about X” includes description of “X.” Numeric ranges are inclusive of the numbers defining the range.

[0259] It is understood that aspects and embodiments of the invention described herein include “comprising,” “consisting,” and “consisting essentially of” aspects and embodiments.

[0260] Cell Viability at High Isoprene Titer

[0261] Isoprene is a hydrophobic molecule secreted by many plants, animals, and microbes. Bacteria, such as *Bacillus*, produce isoprene at fairly low levels. While there is some evidence that plants secrete isoprene to help with thermoprotection, it has been hypothesized that isoprene may act antagonistically to cyanobacteria or fungi, or as an antimicrobial agent. *See, e.g.,* Ladygina et al., *Process Biochemistry* 41:1001-1014 (2006), which is incorporated by reference in its entirety, particularly with respect to isoprene acting antagonistically. Since the very low production levels happening in nature are sufficient to be anti-microbial, it was of great concern that the titers and productivity levels of isoprene necessary for commercialization of isoprene would kill the host microbe.

[0262] We have found methods for producing titers and productivity levels of isoprene for commercialization of isoprene while maintaining cell viability and/or metabolic activity as indicated by carbon dioxide evolution rate or total carbon dioxide evolution rate.

[0263] Provided herein are methods of producing isoprene comprising: a) culturing cells under suitable conditions for production of isoprene; and b) producing isoprene, wherein cells produce greater than about 400 nmole/g_{wcm}/hour of isoprene, and the carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. In some embodiments, the isoprene produced is any concentration or amount disclosed in the section entitled "Exemplary Production of Isoprene." In some embodiments, the amount of isoprene is between about any of 400 nmole/g_{wcm}/hour to 1 mole/g_{wcm}/hour, 400 nmole/g_{wcm}/hour to 1 mmole/g_{wcm}/hour, 400 nmole/g_{wcm}/hour to 40 mmole/g_{wcm}/hour, 400 nmole/g_{wcm}/hour to 4 mmole/g_{wcm}/hour, 1 mmole/g_{wcm}/hour to 1.5 mmole/g_{wcm}/hour, 1.5 mmole/g_{wcm}/hour to 3 mmole/g_{wcm}/hour, 3 mmole/g_{wcm}/hour to 5 mmole/g_{wcm}/hour, 5 mmole/g_{wcm}/hour to 25 mmole/g_{wcm}/hour, 25 mmole/g_{wcm}/hour to 100 mmole/g_{wcm}/hour, 100 mmole/g_{wcm}/hour to 500 mmole/g_{wcm}/hour, or 500 mmole/g_{wcm}/hour to 1000 mmole/g_{wcm}/hour. In some embodiments, the amount of isoprene is about any of 1 mmole/g_{wcm}/hour, 1.5 mmole/g_{wcm}/hour, 2 mmole/g_{wcm}/hour, 3 mmole/g_{wcm}/hour, 4 mmole/g_{wcm}/hour, or 5 mmole/g_{wcm}/hour. In some embodiments, the carbon dioxide evolution rate is between about any of 1×10^{-18} mmol/L/hour to about 1 mol/L/hour, 1 mmol/L/hour to 1 mol/L/hour, 25 mmol/L/hour to 750 mmol/L/hour, 25 mmol/L/hour to 75 mmol/L/hour, 250 mmol/L/hour to 750 mmol/L/hour, or 450 mmol/L/hour to 550 mmol/L/hour. In some embodiments, the carbon dioxide evolution rate is about any of 50 mmol/L/hour, 100 mmol/L/hour, 150 mmol/L/hour, 200 mmol/L/hour, 250 mmol/L/hour, 300 mmol/L/hour, 350 mmol/L/hour, 400 mmol/L/hour, 450 mmol/L/hour, or 500 mmol/L/hour.

[0264] Provided herein are also methods of producing isoprene comprising: a) culturing cells under suitable conditions for production of isoprene; and b) producing isoprene, wherein cells produce greater than about 400 nmole/g_{wcm}/hour of isoprene, and cell viability is reduced by less than about two-fold. In some embodiments, the isoprene produced is any concentration or amount disclosed in the section entitled "Exemplary Production of Isoprene." In some embodiments, the amount of isoprene is between about any of 400 nmole/g_{wcm}/hour to 1 mole/g_{wcm}/hour, 400 nmole/g_{wcm}/hour to 1 mmole/g_{wcm}/hour, 400

nmole/g_{wcm}/hour to 40 mmole/g_{wcm}/hour, 400 nmole/g_{wcm}/hour to 4 mmole/g_{wcm}/hour, 1 mmole/g_{wcm}/hour to 1.5 mmole/g_{wcm}/hour, 1.5 mmole/g_{wcm}/hour to 3 mmole/g_{wcm}/hour, 3 mmole/g_{wcm}/hour to 5 mmole/g_{wcm}/hour, 5 mmole/g_{wcm}/hour to 25 mmole/g_{wcm}/hour, 25 mmole/g_{wcm}/hour to 100 mmole/g_{wcm}/hour, 100 mmole/g_{wcm}/hour to 500 mmole/g_{wcm}/hour, or 500 mmole/g_{wcm}/hour to 1000 mmole/g_{wcm}/hour. In some embodiments, the amount of isoprene is about any of 1 mmole/g_{wcm}/hour, 1.5 mmole/g_{wcm}/hour, 2 mmole/g_{wcm}/hour, 3 mmole/g_{wcm}/hour, 4 mmole/g_{wcm}/hour, or 5 mmole/g_{wcm}/hour. In some embodiments, cell viability is reduced by less than about any of 1.75-fold, 1.5-fold, 1.25-fold, 1-fold, 0.75-fold, 0.5-fold, or 0.25-fold. In some embodiments, cell viability is reduced by about 2-fold.

[0265] Further provided herein are methods of producing isoprene comprising: a) culturing cells under suitable conditions for production of isoprene; and b) producing isoprene, wherein the cumulative total productivity of the isoprene produced by the cells in culture is greater than about 0.2 mg/L_{broth}/hour and the carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. In some embodiments, the cumulative total productivity of isoprene is any concentration or amount disclosed in the section entitled "Exemplary Production of Isoprene." In some embodiments, the cumulative total productivity of the isoprene is between about any of 0.2 mg/L_{broth}/hour to 5 g/L_{broth}/hour, 0.2 mg/L_{broth}/hour to 1 g/L_{broth}/hour, 1 g/L_{broth}/hour to 2.5 g/L_{broth}/hour, 2.5 g/L_{broth}/hour to 5 g/L_{broth}/hour. In some embodiments, the carbon dioxide evolution rate is between about any of 1×10^{-18} mmol/L/hour to about 1 mol/L/hour, 1 mmol/L/hour to 1 mol/L/hour, 25 mmol/L/hour to 750 mmol/L/hour, 25 mmol/L/hour to 75 mmol/L/hour, 250 mmol/L/hour to 750 mmol/L/hour, or 450 mmol/L/hour to 550 mmol/L/hour. In some embodiments, the carbon dioxide evolution rate is about any of 50 mmol/L/hour, 100 mmol/L/hour, 150 mmol/L/hour, 200 mmol/L/hour, 250 mmol/L/hour, 300 mmol/L/hour, 350 mmol/L/hour, 400 mmol/L/hour, 450 mmol/L/hour, or 500 mmol/L/hour.

[0266] Provided herein are methods of producing isoprene comprising: a) culturing cells under suitable conditions for production of isoprene; and b) producing isoprene, wherein the cumulative total productivity of the isoprene produced by the cells in culture is greater than about 0.2 mg/L_{broth}/hour and cell viability is reduced by less than about two-fold. In some embodiments, the cumulative total productivity of isoprene is any concentration or amount disclosed in the section entitled "Exemplary Production of Isoprene." In some embodiments, the cumulative total productivity of the isoprene is between about any of 0.2

mg/L_{broth}/hour to 5 g/L_{broth}/hour, 0.2 mg/L_{broth}/hour to 1 g/L_{broth}/hour, 1 g/L_{broth}/hour to 2.5 g/L_{broth}/hour, 2.5 g/L_{broth}/hour to 5 g/L_{broth}/hour. In some embodiments, cell viability is reduced by less than about any of 1.75-fold, 1.5-fold, 1.25-fold, 1-fold, 0.75-fold, 0.5-fold, or 0.25-fold.

[0267] Methods of producing isoprene are also provided herein comprising: a) culturing cells under suitable conditions for production of isoprene; and b) producing isoprene, wherein the peak concentration of the isoprene produced by the cells in culture is greater than about 10 ng/L_{broth} and the carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. In some embodiments, the peak concentration of isoprene is any concentration or amount disclosed in the section entitled “Exemplary Production of Isoprene.” In some embodiments, the peak concentration of isoprene is between about any of 10 ng/L_{broth} to 500 ng/L_{broth}, 500 ng/L_{broth} to 1 µg/L_{broth}, 1 µg/L_{broth} to 5 µg/L_{broth}, 5 µg/L_{broth} to 50 µg/L_{broth}, 5 µg/L_{broth} to 100 µg/L_{broth}, 5 µg/L_{broth} to 250 µg/L_{broth}, 250 µg/L_{broth} to 500 µg/L_{broth}, 500 µg/L_{broth} to 1 mg/L_{broth}, 1 mg/L_{broth} to 50 mg/L_{broth}, 1 mg/L_{broth} to 100 mg/L_{broth}, 1 mg/L_{broth} to 200 mg/L_{broth}, 10 ng/L_{broth} to 200 mg/L_{broth}, 5 µg/L_{broth} to 100 mg/L_{broth}, or 5 µg/L_{broth} to 200 mg/L_{broth}. In some embodiments, the peak concentration is any of about 10 ng/L_{broth}, 100 ng/L_{broth}, 1 µg/L_{broth}, 5 µg/L_{broth}, 1 mg/L_{broth}, 30 mg/L_{broth}, 100 mg/L_{broth}, or 200 mg/L_{broth}. In some embodiments, the carbon dioxide evolution rate is between about any of 1×10^{-18} mmol/L/hour to about 1 mol/L/hour, 1 mmol/L/hour to 1 mol/L/hour, 25 mmol/L/hour to 750 mmol/L/hour, 25 mmol/L/hour to 75 mmol/L/hour, 250 mmol/L/hour to 750 mmol/L/hour, or 450 mmol/L/hour to 550 mmol/L/hour. In some embodiments, the carbon dioxide evolution rate is about any of 50 mmol/L/hour, 100 mmol/L/hour, 150 mmol/L/hour, 200 mmol/L/hour, 250 mmol/L/hour, 300 mmol/L/hour, 350 mmol/L/hour, 400 mmol/L/hour, 450 mmol/L/hour, or 500 mmol/L/hour.

[0268] In addition, methods of producing isoprene are also provided herein comprising: a) culturing cells under suitable conditions for production of isoprene; and b) producing isoprene, wherein the peak concentration of the isoprene produced by the cells in culture is greater than about 10 ng/L_{broth} and cell viability is reduced by less than about two-fold. In some embodiments, the peak concentration of isoprene is any concentration or amount disclosed in the section entitled “Exemplary Production of Isoprene.” In some embodiments, the peak concentration of isoprene is between about any of 10 ng/L_{broth} to

500 ng/L_{broth}, 500 ng/L_{broth} to 1 µg/L_{broth}, 1 µg/L_{broth} to 5 µg/L_{broth}, 5 µg/L_{broth} to 50 µg/L_{broth}, 5 µg/L_{broth} to 100 µg/L_{broth}, 5 µg/L_{broth} to 250 µg/L_{broth}, 250 µg/L_{broth} to 500 µg/L_{broth}, 500 µg/L_{broth} to 1 mg/L_{broth}, 1 mg/L_{broth} to 50 mg/L_{broth}, 1 mg/L_{broth} to 100 mg/L_{broth}, 1 mg/L_{broth} to 200 mg/L_{broth}, 10 ng/L_{broth} to 200 mg/L_{broth}, 5 µg/L_{broth} to 100 mg/L_{broth}, or 5 µg/L_{broth} to 200 mg/L_{broth}. In some embodiments, the peak concentration is any of about 10 ng/L_{broth}, 100 ng/L_{broth}, 1 µg/L_{broth}, 5 µg/L_{broth}, 1 mg/L_{broth}, 30 mg/L_{broth}, 100 mg/L_{broth}, or 200 mg/L_{broth}. In some embodiments, cell viability is reduced by less than about any of 1.75-fold, 1.5-fold, 1.25-fold, 1-fold, 0.75-fold, 0.5-fold, or 0.25-fold. In some embodiments, cell viability is reduced by about 2-fold.

[0269] Cells in culture are also provided herein comprising a nucleic acid encoding an isoprene synthase polypeptide, wherein the cells produce greater than about 400 nmole/g_{wcm}/hour of isoprene and carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. In some embodiments, the isoprene produced is any concentration or amount disclosed in the section entitled "Exemplary Production of Isoprene." In some embodiments, the amount of isoprene is between about any of 400 nmole/g_{wcm}/hour to 1 mole/g_{wcm}/hour, 400 nmole/g_{wcm}/hour to 1 mmole/g_{wcm}/hour, 400 nmole/g_{wcm}/hour to 40 mmole/g_{wcm}/hour, 400 nmole/g_{wcm}/hour to 4 mmole/g_{wcm}/hour, 1 mmole/g_{wcm}/hour to 1.5 mmole/g_{wcm}/hour, 1.5 mmole/g_{wcm}/hour to 3 mmole/g_{wcm}/hour, 3 mmole/g_{wcm}/hour to 5 mmole/g_{wcm}/hour, 5 mmole/g_{wcm}/hour to 25 mmole/g_{wcm}/hour, 25 mmole/g_{wcm}/hour to 100 mmole/g_{wcm}/hour, 100 mmole/g_{wcm}/hour to 500 mmole/g_{wcm}/hour, or 500 mmole/g_{wcm}/hour to 1000 mmole/g_{wcm}/hour. In some embodiments, the amount of isoprene is about any of 1 mmole/g_{wcm}/hour, 1.5 mmole/g_{wcm}/hour, 2 mmole/g_{wcm}/hour, 3 mmole/g_{wcm}/hour, 4 mmole/g_{wcm}/hour, or 5 mmole/g_{wcm}/hour. In some embodiments, the carbon dioxide evolution rate is between about any of 1×10^{-18} mmol/L/hour to about 1 mol/L/hour, 1 mmol/L/hour to 1 mol/L/hour, 25 mmol/L/hour to 750 mmol/L/hour, 25 mmol/L/hour to 75 mmol/L/hour, 250 mmol/L/hour to 750 mmol/L/hour, or 450 mmol/L/hour to 550 mmol/L/hour. In some embodiments, the carbon dioxide evolution rate is about any of 50 mmol/L/hour, 100 mmol/L/hour, 150 mmol/L/hour, 200 mmol/L/hour, 250 mmol/L/hour, 300 mmol/L/hour, 350 mmol/L/hour, 400 mmol/L/hour, 450 mmol/L/hour, or 500 mmol/L/hour.

[0270] Provided herein are also cells in culture comprising a nucleic acid encoding an isoprene synthase polypeptide, wherein cumulative total productivity of the isoprene

produced by the cells in culture is greater than about 0.2 mg/L_{broth}/hour and carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. In some embodiments, the cumulative total productivity of isoprene is any concentration or amount disclosed in the section entitled “Exemplary Production of Isoprene.” In some embodiments, the cumulative total productivity of the isoprene is between about any of 0.2 mg/L_{broth}/hour to 5 g/L_{broth}/hour, 0.2 mg/L_{broth}/hour to 1 g/L_{broth}/hour, 1 g/L_{broth}/hour to 2.5 g/L_{broth}/hour, 2.5 g/L_{broth}/hour to 5 g/L_{broth}/hour. In some embodiments, the carbon dioxide evolution rate is between about any of 1×10^{-18} mmol/L/hour to about 1 mol/L/hour, 1 mmol/L/hour to 1 mol/L/hour, 25 mmol/L/hour to 750 mmol/L/hour, 25 mmol/L/hour to 75 mmol/L/hour, 250 mmol/L/hour to 750 mmol/L/hour, or 450 mmol/L/hour to 550 mmol/L/hour. In some embodiments, the carbon dioxide evolution rate is about any of 50 mmol/L/hour, 100 mmol/L/hour, 150 mmol/L/hour, 200 mmol/L/hour, 250 mmol/L/hour, 300 mmol/L/hour, 350 mmol/L/hour, 400 mmol/L/hour, 450 mmol/L/hour, or 500 mmol/L/hour.

[0271] In addition, provided herein are cells in culture comprising a nucleic acid encoding an isoprene synthase polypeptide, wherein peak concentration of the isoprene produced by the cells in culture is greater than about 10 ng/L_{broth} and carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour. In some embodiments, the peak concentration of isoprene is any concentration or amount disclosed in the section entitled “Exemplary Production of Isoprene.” In some embodiments, the peak concentration of isoprene is between about any of 10 ng/L_{broth} to 500 ng/L_{broth}, 500 ng/L_{broth} to 1 µg/L_{broth}, 1 µg/L_{broth} to 5 µg/L_{broth}, 5 µg/L_{broth} to 50 µg/L_{broth}, 5 µg/L_{broth} to 100 µg/L_{broth}, 5 µg/L_{broth} to 250 µg/L_{broth}, 250 µg/L_{broth} to 500 µg/L_{broth}, 500 µg/L_{broth} to 1 mg/L_{broth}, 1 mg/L_{broth} to 50 mg/L_{broth}, 1 mg/L_{broth} to 100 mg/L_{broth}, 1 mg/L_{broth} to 200 mg/L_{broth}, 10 ng/L_{broth} to 200 mg/L_{broth}, 5 µg/L_{broth} to 100 mg/L_{broth}, or 5 µg/L_{broth} to 200 mg/L_{broth}. In some embodiments, the peak concentration is any of about 10 ng/L_{broth}, 100 ng/L_{broth}, 1 µg/L_{broth}, 5 µg/L_{broth}, 1 mg/L_{broth}, 30 mg/L_{broth}, 100 mg/L_{broth}, or 200 mg/L_{broth}. In some embodiments, the carbon dioxide evolution rate is between about any of 1×10^{-18} mmol/L/hour to about 1 mol/L/hour, 1 mmol/L/hour to 1 mol/L/hour, 25 mmol/L/hour to 750 mmol/L/hour, 25 mmol/L/hour to 75 mmol/L/hour, 250 mmol/L/hour to 750 mmol/L/hour, or 450 mmol/L/hour to 550 mmol/L/hour. In some embodiments, the carbon dioxide evolution rate is about any of 50 mmol/L/hour, 100 mmol/L/hour, 150 mmol/L/hour, 200

mmol/L/hour, 250 mmol/L/hour, 300 mmol/L/hour, 350 mmol/L/hour, 400 mmol/L/hour, 450 mmol/L/hour, or 500 mmol/L/hour.

[0272] In some embodiments of any of the methods and cells described herein, carbon dioxide evolution rate and/or cell viability of a cell expressing a MVA pathway and/or DXP pathway RNA and/or protein from one or more of a heterologous and/or duplicate copy of a MVA pathway and/or DXP pathway nucleic acid is compared to a control cell lacking one or more of a heterologous and/or duplicate copy of a MVA pathway and/or DXP pathway nucleic acid. In some embodiments, carbon dioxide evolution rate and/or cell viability of a cell expressing a MVA pathway and/or DXP pathway RNA and/or protein from one or more of a heterologous and/or duplicate copy of a MVA pathway and/or DXP pathway nucleic acid under the control of an inducible promoter, wherein the promoter is induced, is compared to a control cell containing one or more of a heterologous and/or duplicate copy of a MVA pathway and/or DXP pathway nucleic acid under the control of an inducible promoter, wherein the promoter is not induced (uninduced). In some embodiments, the inducible promoter is a beta-galactosidase promoter.

Isoprene

[0273] The invention features compositions and methods for the production of isoprene in increased amounts and/or purity. As used herein, the term “isoprene” or “2-methyl-1,3-butadiene” (CAS# 78-79-5) refers to the direct and final volatile C5 hydrocarbon product from the elimination of pyrophosphate from 3,3-dimethylallyl pyrophosphate (DMAPP), and does not involve the linking or polymerization of one or more isopentenyl diphosphate (IPP) molecules to one or more DMAPP molecules.

[0274] The vast majority of isoprene is derived from petrochemical sources as an impure C5 hydrocarbon fraction which requires extensive purification before the material is suitable for polymerization. Several impurities are particularly problematic given their structural similarity to isoprene and the fact that they can act as polymerization catalyst poisons. Such compounds include 1,3-cyclopentadiene, *trans*-1,3-pentadiene, *cis*-1,3-pentadiene, 1,4-pentadiene, 1-pentyne, 2-pentyne, 3-methyl-1-butyne, pent-4-ene-1-yne, *trans*-pent-3-ene-1-yne, *cis*-pent-3-ene-1-yne, 3-hexen-1-ol, 3-hexen-1-yl acetate, limonene, geraniol (trans-3,7-dimethyl-2,6-octadien-1-ol) and citronellol (3,7-dimethyl-6-octen-1-ol) (Fig. 90). In other embodiments, the impurities can be 3-hexen-1-ol, 3-hexen-1-yl acetate,

limonene, geraniol (trans-3,7-dimethyl-2,6-octadien-1-ol) and citronellol (3,7-dimethyl-6-octen-1-ol). In some embodiments, the isoprene composition of the invention is substantially free of any contaminating unsaturated C5 hydrocarbons. As described further in Example 10, no detectable amount of unsaturated C5 hydrocarbons other than isoprene (such as 1,3-cyclopentadiene, *trans*-1,3-pentadiene, *cis*-1,3-pentadiene, 1,4-pentadiene, 1-pentyne, 2-pentyne, 3-methyl-1-butyne, pent-4-ene-1-yne, *trans*-pent-3-ene-1-yne, *cis*-pent-3-ene-1-yne, 3-hexen-1-ol, 3-hexen-1-yl acetate, limonene, geraniol (trans-3,7-dimethyl-2,6-octadien-1-ol) and citronellol (3,7-dimethyl-6-octen-1-ol)) was found in isoprene compositions produced using the methods described herein. Some isoprene compositions produced using the methods described herein contain ethanol, acetone, and C5 prenyl alcohols as determined by GC/MS analysis. All of these components are far more readily removed from the isoprene stream than the isomeric C5 hydrocarbon fractions that are present in isoprene compositions derived from petrochemical sources. Accordingly, in some embodiments, the isoprene compositions of the invention require minimal treatment in order to be of polymerization grade.

[0275] In one aspect, compositions and methods of the invention increase the rate of isoprene production and increase the total amount of isoprene that is produced. For example, cell culture systems that generate 4.8×10^4 nmole/g_{wcm}/hr of isoprene have been produced (Table 1). The efficiency of these systems is demonstrated by the conversion of about 2.2% of the carbon that the cells consume from a cell culture medium into isoprene. As shown in the Examples and Table 2, approximately 3 g of isoprene per liter of broth was generated. If desired, even greater amounts of isoprene can be obtained using other conditions, such as those described herein. In some embodiments, a renewable carbon source is used for the production of isoprene. In some embodiments, the production of isoprene is decoupled from the growth of the cells. In some embodiments, the concentrations of isoprene and any oxidants are within the nonflammable ranges to reduce or eliminate the risk that a fire may occur during production or recovery of isoprene. The compositions and methods of the present invention are desirable because they allow high isoprene yield per cell, high carbon yield, high isoprene purity, high productivity, low energy usage, low production cost and investment, and minimal side reactions. This efficient, large scale, biosynthetic process for isoprene production provides an isoprene source for synthetic isoprene-based rubber and provides a desirable, low-cost alternative to using natural rubber.

[0276] As discussed further below, the amount of isoprene produced by cells can be greatly increased by introducing a heterologous nucleic acid encoding an isoprene synthase polypeptide (*e.g.*, a plant isoprene synthase polypeptide) into the cells. Isoprene synthase polypeptides convert dimethylallyl diphosphate (DMAPP) into isoprene. As shown in the Examples, a heterologous *Pueraria Montana* (kudzu) isoprene synthase polypeptide was expressed in a variety of host cells, such as *Escherichia coli*, *Pantoea citrea*, *Bacillus subtilis*, *Yarrowia lipolytica*, and *Trichoderma reesei*. All of these cells produced more isoprene than the corresponding cells without the heterologous isoprene synthase polypeptide. As illustrated in Tables 1 and 2, large amounts of isoprene are produced using the methods described herein. For example, *B. subtilis* cells with a heterologous isoprene synthase nucleic acid produced approximately 10-fold more isoprene in a 14 liter fermentor than the corresponding control *B. subtilis* cells without the heterologous nucleic acid (Table 2). The production of 300 mg of isoprene per liter of broth (mg/L, wherein the volume of broth includes both the volume of the cell medium and the volume of the cells) by *E. coli* and 30 mg/L by *B. subtilis* in fermentors indicates that significant amounts of isoprene can be generated (Table 2). If desired, isoprene can be produced on an even larger scale or other conditions described herein can be used to further increase the amount of isoprene. The vectors listed in Tables 1 and 2 and the experimental conditions are described in further detail below and in the Examples section.

Table 1: Exemplary yields of isoprene from a shake flask using the cell cultures and methods of the invention. The assay for measuring isoprene production is described in Example I, part II. For this assay, a sample was removed at one or more time points from the shake flask and cultured for 30 minutes. The amount of isoprene produced in this sample was then measured. The headspace concentration and specific rate of isoprene production are listed in Table 1 and described further herein.

**Normalized to an off-gas flow rate of 1 vvm (1 volume off-gas per 1 L_{broth} per minute).

[0277] Additionally, isoprene production by cells that contain a heterologous isoprene synthase nucleic acid can be enhanced by increasing the amount of a 1-deoxy-D-xylulose-5-phosphate synthase (DXS) polypeptide and/or an isopentenyl diphosphate isomerase

(IDI) polypeptide expressed by the cells. For example, a DXS nucleic acid and/or an IDI nucleic acid can be introduced into the cells. The DXS nucleic acid may be a heterologous nucleic acid or a duplicate copy of an endogenous nucleic acid. Similarly, the IDI nucleic acid may be a heterologous nucleic acid or a duplicate copy of an endogenous nucleic acid. In some embodiments, the amount of DXS and/or IDI polypeptide is increased by replacing the endogenous DXS and/or IDI promoters or regulatory regions with other promoters and/or regulatory regions that result in greater transcription of the DXS and/or IDI nucleic acids. In some embodiments, the cells contain both a heterologous nucleic acid encoding an isoprene synthase polypeptide (*e.g.*, a plant isoprene synthase nucleic acid) and a duplicate copy of an endogenous nucleic acid encoding an isoprene synthase polypeptide.

[0278] The encoded DXS and IDI polypeptides are part of the DXP pathway for the biosynthesis of isoprene (Figure 19A). DXS polypeptides convert pyruvate and D-glyceraldehyde-3-phosphate into 1-deoxy-D-xylulose-5-phosphate. While not intending to be bound by any particular theory, it is believed that increasing the amount of DXS polypeptide increases the flow of carbon through the DXP pathway, leading to greater isoprene production. IDI polypeptides catalyze the interconversion of isopentenyl diphosphate (IPP) and dimethylallyl diphosphate (DMAPP). While not intending to be bound by any particular theory, it is believed that increasing the amount of IDI polypeptide in cells increases the amount (and conversion rate) of IPP that is converted into DMAPP, which in turn is converted into isoprene.

[0279] For example, fermentation of *E. coli* cells with a kudzu isoprene synthase, *S. cerevisiae* IDI, and *E. coli* DXS nucleic acids was used to produce isoprene. The levels of isoprene varied from 50 to 300 µg/L over a time period of 15 hours (Example 7, part VII).

[0280] In some embodiments, the presence of heterologous or extra endogenous isoprene synthase, IDI, and DXS nucleic acids causes cells to grow more reproducibly or remain viable for longer compared to the corresponding cell with only one or two of these heterologous or extra endogenous nucleic acids. For example, cells containing heterologous isoprene synthase, IDI, and DXS nucleic acids grew better than cells with only heterologous isoprene synthase and DXS nucleic acids or with only a heterologous isoprene synthase nucleic acid. Also, heterologous isoprene synthase, IDI, and DXS nucleic acids were successfully operably linked to a strong promoter on a high copy

plasmid that was maintained by *E. coli* cells, suggesting that large amounts of these polypeptides could be expressed in the cells without causing an excessive amount of toxicity to the cells. While not intending to be bound to a particular theory, it is believed that the presence of heterologous or extra endogenous isoprene synthase and IDI nucleic acids may reduce the amount of one or more potentially toxic intermediates that would otherwise accumulate if only a heterologous or extra endogenous DXS nucleic acid was present in the cells.

[0281] In some embodiments, the production of isoprene by cells by cells that contain a heterologous isoprene synthase nucleic acid is augmented by increasing the amount of a MVA polypeptide expressed by the cells (Figures 19A and 19B). Exemplary MVA pathways polypeptides include any of the following polypeptides: acetyl-CoA acetyltransferase (AA-CoA thiolase) polypeptides, 3-hydroxy-3-methylglutaryl-CoA synthase (HMG-CoA synthase) polypeptides, 3-hydroxy-3-methylglutaryl-CoA reductase (HMG-CoA reductase) polypeptides, mevalonate kinase (MVK) polypeptides, phosphomevalonate kinase (PMK) polypeptides, diphosphomevalonate decarboxylase (MVD) polypeptides, phosphomevalonate decarboxylase (PMDC) polypeptides, isopentenyl phosphate kinase (IPK) polypeptides, IDI polypeptides, and polypeptides (*e.g.*, fusion polypeptides) having an activity of two or more MVA pathway polypeptides. For example, one or more MVA pathway nucleic acids can be introduced into the cells. In some embodiments, the cells contain the upper MVA pathway, which includes AA-CoA thiolase, HMG-CoA synthase, and HMG-CoA reductase nucleic acids. In some embodiments, the cells contain the lower MVA pathway, which includes MVK, PMK, MVD, and IDI nucleic acids. In some embodiments, the cells contain an entire MVA pathway that includes AA-CoA thiolase, HMG-CoA synthase, HMG-CoA reductase, MVK, PMK, MVD, and IDI nucleic acids. In some embodiments, the cells contain an entire MVA pathway that includes AA-CoA thiolase, HMG-CoA synthase, HMG-CoA reductase, MVK, PMDC, IPK, and IDI nucleic acids. The MVA pathway nucleic acids may be heterologous nucleic acids or duplicate copies of endogenous nucleic acids. In some embodiments, the amount of one or more MVA pathway polypeptides is increased by replacing the endogenous promoters or regulatory regions for the MVA pathway nucleic acids with other promoters and/or regulatory regions that result in greater transcription of the MVA pathway nucleic acids. In some embodiments, the cells contain both a heterologous nucleic acid encoding an isoprene synthase polypeptide (*e.g.*, a plant

isoprene synthase nucleic acid) and a duplicate copy of an endogenous nucleic acid encoding an isoprene synthase polypeptide.

[0282] For example, *E. coli* cells containing a nucleic acid encoding a kudzu isoprene synthase polypeptide and nucleic acids encoding *Saccharomyces cerevisiae* MVK, PMK, MVD, and IDI polypeptides generated isoprene at a rate of 6.67×10^{-4} mol/L_{broth}/OD₆₀₀/hr (see Example 8). Additionally, a 14 liter fermentation of *E. coli* cells with nucleic acids encoding *Enterococcus faecalis* AA-CoA thiolase, HMG-CoA synthase, and HMG-CoA reductase polypeptides produced 22 grams of mevalonic acid (an intermediate of the MVA pathway). A shake flask of these cells produced 2-4 grams of mevalonic acid per liter. These results indicate that heterologous MVA pathways nucleic acids are active in *E. coli*. *E. coli* cells that contain nucleic acids for both the upper MVA pathway and the lower MVA pathway as well as a kudzu isoprene synthase (strain MCM 127) produced significantly more isoprene (874 ug/L) compared to *E. coli* cells with nucleic acids for only the lower MVA pathway and the kudzu isoprene synthase (strain MCM 131) (see Table 3 and Example 8, part VIII).

[0283] In some embodiments, at least a portion of the cells maintain the heterologous isoprene synthase, DXS, IDI, and/or MVA pathway nucleic acid for at least about 5, 10, 20, 50, 75, 100, 200, 300, or more cell divisions in a continuous culture (such as a continuous culture without dilution). In some embodiments of any of the aspects of the invention, the nucleic acid comprising the heterologous or duplicate copy of an endogenous isoprene synthase, DXS, IDI, and/or MVA pathway nucleic acid also comprises a selective marker, such as a kanamycin, ampicillin, carbenicillin, gentamicin, hygromycin, phleomycin, bleomycin, neomycin, or chloramphenicol antibiotic resistance nucleic acid.

[0284] As indicated in Example 7, part VI, the amount of isoprene produced can be further increased by adding yeast extract to the cell culture medium. In this example, the amount of isoprene produced was linearly proportional to the amount of yeast extract in the cell medium for the concentrations tested (Figure 48C). Additionally, approximately 0.11 grams of isoprene per liter of broth was produced from a cell medium with yeast extract and glucose (Example 7, part VIII). Both of these experiments used *E. coli* cells with kudzu isoprene synthase, *S. cerevisiae* IDI, and *E. coli* DXS nucleic acids to produce isoprene. Increasing the amount of yeast extract in the presence of glucose resulted in

more isoprene being produced than increasing the amount of glucose in the presence of yeast extract. Also, increasing the amount of yeast extract allowed the cells to produce a high level of isoprene for a longer length of time and improved the health of the cells.

[0285] Isoprene production was also demonstrated using three types of hydrolyzed biomass (bagasse, corn stover, and soft wood pulp) as the carbon source (Figures 46A-C). *E. coli* cells with kudzu isoprene synthase, *S. cerevisiae* IDI, and *E. coli* DXS nucleic acids produced as much isoprene from these hydrolyzed biomass carbon sources as from the equivalent amount of glucose (*e.g.*, 1% glucose, w/v). If desired, any other biomass carbon source can be used in the compositions and methods of the invention. Biomass carbon sources are desirable because they are cheaper than many conventional cell mediums, thereby facilitating the economical production of isoprene.

[0286] Additionally, invert sugar was shown to function as a carbon source for the generation of isoprene (Figures 47C and 96-98). For example, 2.4 g/L of isoprene was produced from cells expressing MVA pathway polypeptides and a Kudzu isoprene synthase (Example 8, part XV). Glycerol was also used as a carbon source for the generation of 2.2 mg/L of isoprene from cells expressing a Kudzu isoprene synthase (Example 8, part XIV). Expressing a DXS nucleic acid, an IDI nucleic acid, and/or one or more MVA pathway nucleic acids (such as nucleic acids encoding the entire MVA pathway) in addition to an isoprene synthase nucleic acid may increase the production of isoprene from glycerol.

[0287] In some embodiments, an oil is included in the cell medium. For example, *B. subtilis* cells containing a kudzu isoprene synthase nucleic acid produced isoprene when cultured in a cell medium containing an oil and a source of glucose (Example 4, part III). In some embodiments, more than one oil (such as 2, 3, 4, 5, or more oils) is included in the cell medium. While not intending to be bound to any particular theory, it is believed that (i) the oil may increase the amount of carbon in the cells that is available for conversion to isoprene, (ii) the oil may increase the amount of acetyl-CoA in the cells, thereby increasing the carbon flow through the MVA pathway, and/or (ii) the oil may provide extra nutrients to the cells, which is desirable since a lot of the carbon in the cells is converted to isoprene rather than other products. In some embodiments, cells that are cultured in a cell medium containing oil naturally use the MVA pathway to produce isoprene or are genetically modified to contain nucleic acids for the entire MVA pathway.

In some embodiments, the oil is partially or completely hydrolyzed before being added to the cell culture medium to facilitate the use of the oil by the host cells.

[0288] One of the major hurdles to commercial production of small molecules such as isoprene in cells (*e.g.*, bacteria) is the decoupling of production of the molecule from growth of the cells. In some embodiments for the commercially viable production of isoprene, a significant amount of the carbon from the feedstock is converted to isoprene, rather than to the growth and maintenance of the cells ("carbon efficiency"). In various embodiments, the cells convert greater than or about 0.0015, 0.002, 0.005, 0.01, 0.02, 0.05, 0.1, 0.12, 0.14, 0.16, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0, 1.2, 1.4, 1.6, 1.8, 2.0, 2.5, 3.0, 3.5, 4.0, 5.0, 6.0, 7.0, or 8.0% of the carbon in the cell culture medium into isoprene. In particular embodiments, a significant portion of the carbon from the feedstock that is converted to downstream products is converted to isoprene. As described further in Example 11, *E. coli* cells expressing MVA pathway and kudzu isoprene synthase nucleic acids exhibited decoupling of the production of isoprene or the intermediate mevalonic acid from growth, resulting in high carbon efficiency. In particular, mevalonic acid was formed from cells expressing the upper MVA pathway from *Enterococcus faecalis*. Isoprene was formed from cells expressing the upper MVA pathway from *Enterococcus faecalis*, the lower MVA pathway from *Saccharomyces cerevisiae*, and the isoprene synthase from *Pueraria montana* (Kudzu). This decoupling of isoprene or mevalonic acid production from growth was demonstrated in four different strains of *E. coli*: BL21(LDE3), BL21(LDE3) Tuner, FM5, and MG1655. The first two *E. coli* strains are B strains, and the latter two are K12 strains. Decoupling of production from growth was also demonstrated in a variant of MG1655 with *ack* and *pta* genes deleted. This variant also demonstrated less production of acetate.

Production of Ethylene

[0289] The invention features methods for the production of ethylene (CAS# 74-85-1) using cell culture. In some embodiments, ethylene refers to the final volatile C2 hydrocarbon product from the conversion of 2-oxoglutarate, an intermediate of the tricarboxylic acid (TCA) cycle by the ethylene-forming enzyme (efe). Ethylene is used in the manufacture of polymers such as polyethylene, polyester, polyvinyl chloride, and polystyrene, as well as fibers and other organic chemicals.

[0290] Provided herein are methods of producing a compound, wherein the compound has one or more characteristics selected from the group consisting of (a) a Henry's law coefficient of less than about 250 M/atm and (b) a solubility in water of less than about 100 g/L. In some embodiments, the method comprises: a) culturing cells under suitable conditions for production of the compound, wherein gas is added (such as the addition of gas to a system such as a fermentation system) at a gas sparging rate between about 0 vvm to about 2 vvm; and b) producing the compound. In other embodiments, the method comprises: a) culturing cells under suitable conditions for production of the compound; b) producing the compound; and c) recovering the compound in the gas phase. In some embodiments, the method comprises: a) culturing cells under suitable conditions for production of the compound; b) producing the compound; and c) recovering the compound from the gas phase. In some embodiments, the Henry's law coefficient of the compound is less than about any of 200 M/atm, 150 M/atm, 100 M/atm, 75 M/atm, 50 M/atm, 25 M/atm, 10 M/atm, 5 M/atm, or 1 M/atm. In some embodiments, the solubility in water of the compound is less than about any of 75 g/L, 50 g/L, 25 g/L, 10 g/L, 5 g/L, or 1 g/L. In some embodiments, the compound is selected from a group consisting of isoprene, an aldehyde (*e.g.*, acetaldehyde), a ketone (*e.g.*, acetone, methyl ethyl ketone or 2-butanone), an alcohol (*e.g.*, methanol, ethanol, 1-butanol, or C5 alcohols such as 3-methyl-3-buten-1-ol or 3-methyl-2-buten-1-ol), an ester of an alcohol (*e.g.*, ethyl acetate, esters of 3-methyl-2-buten-1-ol or acetyl esters of C5 alcohols), a hemiterpene, a monoterpene, a sesquiterpene, and C1 to C5 hydrocarbons (*e.g.*, methane, ethane, ethylene, or propylene). In some embodiments, the C1 to C5 hydrocarbons are saturated, unsaturated, or branched. In some embodiments, the C1 to C5 hydrocarbon is an unsaturated aliphatic hydrocarbon (*e.g.* ethylene, propene, butylene, or isobutylene). In some embodiments, the C1 to C5 hydrocarbon is a diolefin. In particular embodiments, the compound is isoprene. In other particular embodiments, the compound is ethylene. In some embodiments, isoprene and ethylene are co-produced. In some embodiments of the methods of producing any of the compounds described above, the gas sparging rate is between about any of 0 vvm to 0.1 vvm, 0.1 vvm to 1 vvm, 0.2 vvm to 1 vvm, or 0.5 vvm to 1 vvm. In some embodiments of the methods of producing any of the compounds described above, the gas sparging rate is 0.0 vvm.

[0291] In one aspect, the invention features methods of producing ethylene. In some embodiments, the method comprises: a) culturing cells under suitable conditions for

production of ethylene, wherein gas is added (such as the addition of gas to a system such as a fermentation system) at a gas sparging rate between about 0.01 vvm to about 2 vvm; b) producing ethylene. In other embodiments, the method comprises: a) culturing cells under suitable conditions for production of ethylene; and b) producing ethylene; and c) recovering the ethylene in the gas phase. In some embodiments of the methods of producing ethylene, the gas sparging rate is between about any of 0.0 vvm to 0.1 vvm, 0.1 vvm to 1 vvm, 0.2 vvm to 1 vvm, or 0.5 vvm to 1 vvm. In some embodiments of the methods of producing ethylene, the gas sparging rate is 0.0 vvm.

[0292] In one aspect, the invention features cells in culture that produce a compound, wherein the compound has one or more characteristics selected from the group consisting of (a) a Henry's law coefficient of less than about 250 M/atm and (b) a solubility in water of less than about 100 g/L. In some embodiments, the cells have a heterologous nucleic acid that (i) encodes a synthase polypeptide capable of producing the compound and (ii) is operably linked to a promoter. In some embodiments, the compound produced is ethylene and the synthase polypeptide is ethylene-forming enzyme (efe). In some embodiments, the promoter is the promoter region of the *ffh* gene of *E. coli*, wherein the *ffh* promoter drives constitutive expression of efe. In some embodiments, the cells are cultured in a culture medium that includes one or more carbon source(s), such as, but not limited to, a carbohydrate, glycerol, glycerine, dihydroxyacetone, one-carbon source, oil, animal fat, animal oil, fatty acid, lipid, phospholipid, glycerolipid, monoglyceride, diglyceride, triglyceride, renewable carbon source, polypeptide (*e.g.*, a microbial or plant protein or peptide), yeast extract, component from a yeast extract. In some embodiments, the cells are cultured under limited glucose conditions.

[0293] If isoprene and ethylene are co-produced, then they can be separated during recovery as described herein or by other means known to one of skill in the art. In one aspect of the invention, ethylene is recovered by adsorption. In some embodiments, ethylene is adsorbed on a silver-modified clay. In some embodiments, fermentation off-gas is dehumidified and run into a silver-modified clay filter in order to remove ethylene from the off-gas stream, followed by desorption of the ethylene from the silver-clay filter using a pressure swing cycle. In some embodiments, the fermentation off-gas is further treated before introduction into the silver-clay filter by sparging through an aqueous sodium

hydroxide solution in order to remove carbon dioxide. In another aspect of the invention, ethylene is recovered by cryogenic separation or absorption/stripping.

Exemplary Polypeptides and Nucleic Acids

[0294] Various isoprene synthase, efe, DXS, IDI, and/or MVA pathway polypeptides and nucleic acids can be used in the compositions and methods of the invention.

[0295] As used herein, “polypeptides” includes polypeptides, proteins, peptides, fragments of polypeptides, and fusion polypeptides. In some embodiments, the fusion polypeptide includes part or all of a first polypeptide (*e.g.*, an isoprene synthase, efe, DXS, IDI, or MVA pathway polypeptide or catalytically active fragment thereof) and may optionally include part or all of a second polypeptide (*e.g.*, a peptide that facilitates purification or detection of the fusion polypeptide, such as a His-tag). In some embodiments, the fusion polypeptide has an activity of two or more MVA pathway polypeptides (such as AA-CoA thiolase and HMG-CoA reductase polypeptides). In some embodiments, the polypeptide is a naturally-occurring polypeptide (such as the polypeptide encoded by an *Enterococcus faecalis mvaE* nucleic acid) that has an activity of two or more MVA pathway polypeptides.

[0296] In various embodiments, a polypeptide has at least or about 50, 100, 150, 175, 200, 250, 300, 350, 400, or more amino acids. In some embodiments, the polypeptide fragment contains at least or about 25, 50, 75, 100, 150, 200, 300, or more contiguous amino acids from a full-length polypeptide and has at least or about 5%, 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 95%, or 100% of an activity of a corresponding full-length polypeptide. In particular embodiments, the polypeptide includes a segment of or the entire amino acid sequence of any naturally-occurring isoprene synthase, efe, DXS, IDI, or MVA pathway polypeptide. In some embodiments, the polypeptide has one or more mutations compared to the sequence of a wild-type (*i.e.*, a sequence occurring in nature) isoprene synthase, efe, DXS, IDI, or MVA pathway polypeptide.

[0297] In some embodiments, the polypeptide is an isolated polypeptide. As used herein, an “isolated polypeptide” is not part of a library of polypeptides, such as a library of 2, 5, 10, 20, 50 or more different polypeptides and is separated from at least one component with which it occurs in nature. An isolated polypeptide can be obtained, for example, by expression of a recombinant nucleic acid encoding the polypeptide.

[0298] In some embodiments, the polypeptide is a heterologous polypeptide. By “heterologous polypeptide” is meant a polypeptide whose amino acid sequence is not identical to that of another polypeptide naturally expressed in the same host cell. In particular, a heterologous polypeptide is not identical to a wild-type nucleic acid that is found in the same host cell in nature.

[0299] As used herein, a “nucleic acid” refers to one or two or more deoxyribonucleotides and/or ribonucleotides in either single or double-stranded form. In some embodiments, the nucleic acid is a recombinant nucleic acid. By “recombinant nucleic acid” means a nucleic acid of interest that is free of one or more nucleic acids (*e.g.*, genes) which, in the genome occurring in nature of the organism from which the nucleic acid of interest is derived, flank the nucleic acid of interest. The term therefore includes, for example, a recombinant DNA which is incorporated into a vector, into an autonomously replicating plasmid or virus, or into the genomic DNA of a prokaryote or eukaryote, or which exists as a separate molecule (*e.g.*, a cDNA, a genomic DNA fragment, or a cDNA fragment produced by PCR or restriction endonuclease digestion) independent of other sequences. In various embodiments, a nucleic acid is a recombinant nucleic acid. In some embodiments, an isoprene synthase, *efe*, DXS, IDI, or MVA pathway nucleic acid is operably linked to another nucleic acid encoding all or a portion of another polypeptide such that the recombinant nucleic acid encodes a fusion polypeptide that includes an isoprene synthase, *efe*, DXS, IDI, or MVA pathway polypeptide and all or part of another polypeptide (*e.g.*, a peptide that facilitates purification or detection of the fusion polypeptide, such as a His-tag). In some embodiments, part or all of a recombinant nucleic acid is chemically synthesized. It is to be understood that mutations, including single nucleotide mutations, can occur within a nucleic acid as defined herein.

[0300] In some embodiments, the nucleic acid is a heterologous nucleic acid. By “heterologous nucleic acid” is meant a nucleic acid whose nucleic acid sequence is not identical to that of another nucleic acid naturally found in the same host cell.

[0301] In particular embodiments, the nucleic acid includes a segment of or the entire nucleic acid sequence of any naturally-occurring isoprene synthase, *efe*, DXS, IDI, or MVA pathway nucleic acid. In some embodiments, the nucleic acid includes at least or about 50, 100, 150, 200, 300, 400, 500, 600, 700, 800, or more contiguous nucleotides from a naturally-occurring isoprene synthase nucleic acid, *efe* nucleic acid, DXS, IDI, or MVA

pathway nucleic acid. In some embodiments, the nucleic acid has one or more mutations compared to the sequence of a wild-type (*i.e.*, a sequence occurring in nature) isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid. In some embodiments, the nucleic acid has one or more mutations (*e.g.*, a silent mutation) that increase the transcription or translation of isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid. In some embodiments, the nucleic acid is a degenerate variant of any nucleic acid encoding an isoprene synthase, efe, DXS, IDI, or MVA pathway polypeptide.

[0302] “Codon degeneracy” refers to divergence in the genetic code permitting variation of the nucleotide sequence without affecting the amino acid sequence of an encoded polypeptide. The skilled artisan is well aware of the “codon-bias” exhibited by a specific host cell in usage of nucleotide codons to specify a given amino acid. Therefore, when synthesizing a nucleic acid for improved expression in a host cell, it is desirable in some embodiments to design the nucleic acid such that its frequency of codon usage approaches the frequency of preferred codon usage of the host cell.

[0303] The accession numbers of exemplary isoprene synthase, DXS, IDI, and/or MVA pathway polypeptides and nucleic acids are listed in Appendix 1 (the accession numbers of Appendix 1 and their corresponding sequences are herein incorporated by reference in their entireties, particularly with respect to the amino acid and nucleic acid sequences of isoprene synthase, DXS, IDI, and/or MVA pathway polypeptides and nucleic acids). The Kegg database also contains the amino acid and nucleic acid sequences of numerous exemplary isoprene synthase, DXS, IDI, and/or MVA pathway polypeptides and nucleic acids (*see*, for example, the world-wide web at “genome.jp/kegg/pathway/map/map00100.html” and the sequences therein, which are each hereby incorporated by reference in their entireties, particularly with respect to the amino acid and nucleic acid sequences of isoprene synthase, DXS, IDI, and/or MVA pathway polypeptides and nucleic acids). In some embodiments, one or more of the isoprene synthase, DXS, IDI, and/or MVA pathway polypeptides and/or nucleic acids have a sequence identical to a sequence publicly available on December 12, 2007 or September 14, 2008 such as any of the sequences that correspond to any of the accession numbers in Appendix 1 or any of the sequences present in the Kegg database. Additional exemplary isoprene synthase, DXS, IDI, and/or MVA pathway polypeptides and nucleic acids are described further below.

Exemplary Isoprene Synthase Polypeptides and Nucleic Acids

[0304] As noted above, isoprene synthase polypeptides convert dimethylallyl diphosphate (DMAPP) into isoprene. Exemplary isoprene synthase polypeptides include polypeptides, fragments of polypeptides, peptides, and fusions polypeptides that have at least one activity of an isoprene synthase polypeptide. Standard methods can be used to determine whether a polypeptide has isoprene synthase polypeptide activity by measuring the ability of the polypeptide to convert DMAPP into isoprene *in vitro*, in a cell extract, or *in vivo*. In an exemplary assay, cell extracts are prepared by growing a strain (*e.g.*, the *E. coli*/pTrcKudzu strain described herein) in the shake flask method as described in Example 1. After induction is complete, approximately 10 mL of cells are pelleted by centrifugation at 7000 x g for 10 minutes and resuspended in 5 ml of PEB without glycerol. The cells are lysed using a French Pressure cell using standard procedures. Alternatively the cells are treated with lysozyme (Ready-Lyse lysozyme solution; EpiCentre) after a freeze/thaw at -80°C.

[0305] Isoprene synthase polypeptide activity in the cell extract can be measured, for example, as described in Silver *et al.*, J. Biol. Chem. 270:13010-13016, 1995 and references therein, which are each hereby incorporated by reference in their entireties, particularly with respect to assays for isoprene synthase polypeptide activity. DMAPP (Sigma) is evaporated to dryness under a stream of nitrogen and rehydrated to a concentration of 100 mM in 100 mM potassium phosphate buffer pH 8.2 and stored at -20 °C. To perform the assay, a solution of 5 µL of 1M MgCl₂, 1 mM (250 µg/ml) DMAPP, 65 µL of Plant Extract Buffer (PEB) (50 mM Tris-HCl, pH 8.0, 20 mM MgCl₂, 5% glycerol, and 2 mM DTT) is added to 25 µL of cell extract in a 20 ml Headspace vial with a metal screw cap and teflon coated silicon septum (Agilent Technologies) and cultured at 37 °C for 15 minutes with shaking. The reaction is quenched by adding 200 µL of 250 mM EDTA and quantified by GC/MS as described in Example 1, part II.

[0306] Exemplary isoprene synthase nucleic acids include nucleic acids that encode a polypeptide, fragment of a polypeptide, peptide, or fusion polypeptide that has at least one activity of an isoprene synthase polypeptide. Exemplary isoprene synthase polypeptides and nucleic acids include naturally-occurring polypeptides and nucleic acids from any of the source organisms described herein as well as mutant polypeptides and nucleic acids derived from any of the source organisms described herein.

[0307] In some embodiments, the isoprene synthase polypeptide or nucleic acid is from the family Fabaceae, such as the Faboideae subfamily. In some embodiments, the isoprene synthase polypeptide or nucleic acid is a polypeptide or nucleic acid from *Pueraria montana* (kudzu) (Sharkey *et al.*, Plant Physiology 137: 700-712, 2005), *Pueraria lobata*, poplar (such as *Populus alba*, *Populus nigra*, *Populus trichocarpa*, or *Populus alba x tremula* (CAC35696) Miller *et al.*, Planta 213: 483-487, 2001) aspen (such as *Populus tremuloides*) Silver *et al.*, JBC 270(22): 13010-1316, 1995), or English Oak (*Quercus robur*) (Zimmer *et al.*, WO 98/02550), which are each hereby incorporated by reference in their entireties, particularly with respect to isoprene synthase nucleic acids and the expression of isoprene synthase polypeptides. Suitable isoprene synthases include, but are not limited to, those identified by Genbank Accession Nos. AY341431, AY316691, AY279379, AJ457070, and AY182241, which are each hereby incorporated by reference in their entireties, particularly with respect to sequences of isoprene synthase nucleic acids and polypeptides. In some embodiments, the isoprene synthase polypeptide or nucleic acid is not a naturally-occurring polypeptide or nucleic acid from *Quercus robur* (*i.e.*, the isoprene synthase polypeptide or nucleic acid is an isoprene synthase polypeptide or nucleic acid other than a naturally-occurring polypeptide or nucleic acid from *Quercus robur*). In some embodiments, the isoprene synthase nucleic acid or polypeptide is a naturally-occurring polypeptide or nucleic acid from poplar. In some embodiments, the isoprene synthase nucleic acid or polypeptide is not a naturally-occurring polypeptide or nucleic acid from poplar.

Exemplary efe Polypeptides and Nucleic Acids

[0308] As noted above, ethylene-forming enzyme (efe) polypeptides convert 2-oxoglutarate into ethylene. Exemplary efe polypeptides include polypeptides, fragments of polypeptides, peptides, and fusions polypeptides that have at least one activity of an efe polypeptide. A suitable ethylene-forming enzyme includes, but is not limited to, that identified by Genbank Accession No. EF175870, which is hereby incorporated by reference in its entirety, particularly with respect to the sequences of efe nucleic acids and polypeptides. Standard methods (such as those described herein) can be used to determine whether a polypeptide has efe polypeptide activity by measuring the ability of the polypeptide to convert 2-oxoglutarate into ethylene *in vitro*, in a cell extract, or *in vivo*. Exemplary efe nucleic acids include nucleic acids that encode a polypeptide, fragment of a

polypeptide, peptide, or fusion polypeptide that has at least one activity of an efe polypeptide. Exemplary efe polypeptides and nucleic acids include naturally-occurring polypeptides and nucleic acids from any of the source organisms described herein as well as mutant polypeptides and nucleic acids derived from any of the source organisms described herein.

Exemplary DXS Polypeptides and Nucleic Acids

[0309] As noted above, 1-deoxy-D-xylulose-5-phosphate synthase (DXS) polypeptides convert pyruvate and D-glyceraldehyde-3-phosphate into 1-deoxy-D-xylulose-5-phosphate. Exemplary DXS polypeptides include polypeptides, fragments of polypeptides, peptides, and fusions polypeptides that have at least one activity of a DXS polypeptide. Standard methods (such as those described herein) can be used to determine whether a polypeptide has DXS polypeptide activity by measuring the ability of the polypeptide to convert pyruvate and D-glyceraldehyde-3-phosphate into 1-deoxy-D-xylulose-5-phosphate *in vitro*, in a cell extract, or *in vivo*. Exemplary DXS nucleic acids include nucleic acids that encode a polypeptide, fragment of a polypeptide, peptide, or fusion polypeptide that has at least one activity of a DXS polypeptide. Exemplary DXS polypeptides and nucleic acids include naturally-occurring polypeptides and nucleic acids from any of the source organisms described herein as well as mutant polypeptides and nucleic acids derived from any of the source organisms described herein.

Exemplary IDI Polypeptides and Nucleic Acids

[0310] Isopentenyl diphosphate isomerase polypeptides (isopentenyl-diphosphate delta-isomerase or IDI) catalyses the interconversion of isopentenyl diphosphate (IPP) and dimethylallyl diphosphate (DMAPP) (*e.g.*, converting IPP into DMAPP and/or converting DMAPP into IPP). Exemplary IDI polypeptides include polypeptides, fragments of polypeptides, peptides, and fusions polypeptides that have at least one activity of an IDI polypeptide. Standard methods (such as those described herein) can be used to determine whether a polypeptide has IDI polypeptide activity by measuring the ability of the polypeptide to interconvert IPP and DMAPP *in vitro*, in a cell extract, or *in vivo*. Exemplary IDI nucleic acids include nucleic acids that encode a polypeptide, fragment of a polypeptide, peptide, or fusion polypeptide that has at least one activity of an IDI polypeptide. In one embodiment, a diphosphomevalonate decarboxylase-IDI fusion from

Coxiella burnetti is made. In another embodiment, an IDI-IspS (isoprene synthase) fusion is made. Exemplary IDI polypeptides and nucleic acids include naturally-occurring polypeptides and nucleic acids from any of the source organisms described herein as well as mutant polypeptides and nucleic acids derived from any of the source organisms described herein.

Exemplary MVA Pathway Polypeptides and Nucleic Acids

[0311] Exemplary MVA pathway polypeptides include acetyl-CoA acetyltransferase (AA-CoA thiolase) polypeptides, 3-hydroxy-3-methylglutaryl-CoA synthase (HMG-CoA synthase) polypeptides, 3-hydroxy-3-methylglutaryl-CoA reductase (HMG-CoA reductase) polypeptides, mevalonate kinase (MVK) polypeptides, phosphomevalonate kinase (PMK) polypeptides, diphosphomevalonate decarboxylase (MVD) polypeptides, phosphomevalonate decarboxylase (PMDC) polypeptides, isopentenyl phosphate kinase (IPK) polypeptides, IDI polypeptides, and polypeptides (*e.g.*, fusion polypeptides) having an activity of two or more MVA pathway polypeptides. In particular, MVA pathway polypeptides include polypeptides, fragments of polypeptides, peptides, and fusions polypeptides that have at least one activity of an MVA pathway polypeptide. Exemplary MVA pathway nucleic acids include nucleic acids that encode a polypeptide, fragment of a polypeptide, peptide, or fusion polypeptide that has at least one activity of an MVA pathway polypeptide. Exemplary MVA pathway polypeptides and nucleic acids include naturally-occurring polypeptides and nucleic acids from any of the source organisms described herein as well as mutant polypeptides and nucleic acids derived from any of the source organisms described herein.

[0312] In particular, acetyl-CoA acetyltransferase polypeptides (AA-CoA thiolase or AACT) convert two molecules of acetyl-CoA into acetoacetyl-CoA. Standard methods (such as those described herein) can be used to determine whether a polypeptide has AA-CoA thiolase polypeptide activity by measuring the ability of the polypeptide to convert two molecules of acetyl-CoA into acetoacetyl-CoA *in vitro*, in a cell extract, or *in vivo*.

[0313] 3-hydroxy-3-methylglutaryl-CoA synthase (HMG-CoA synthase or HMGS) polypeptides convert acetoacetyl-CoA into 3-hydroxy-3-methylglutaryl-CoA. Standard methods (such as those described herein) can be used to determine whether a polypeptide has HMG-CoA synthase polypeptide activity by measuring the ability of the polypeptide

to convert acetoacetyl-CoA into 3-hydroxy-3-methylglutaryl-CoA *in vitro*, in a cell extract, or *in vivo*.

[0314] 3-hydroxy-3-methylglutaryl-CoA reductase (HMG-CoA reductase or HMGR) polypeptides convert 3-hydroxy-3-methylglutaryl-CoA into mevalonate. Standard methods (such as those described herein) can be used to determine whether a polypeptide has HMG-CoA reductase polypeptide activity by measuring the ability of the polypeptide to convert 3-hydroxy-3-methylglutaryl-CoA into mevalonate *in vitro*, in a cell extract, or *in vivo*.

[0315] Mevalonate kinase (MVK) polypeptides phosphorylates mevalonate to form mevalonate-5-phosphate. Standard methods (such as those described herein) can be used to determine whether a polypeptide has MVK polypeptide activity by measuring the ability of the polypeptide to convert mevalonate into mevalonate-5-phosphate *in vitro*, in a cell extract, or *in vivo*.

[0316] Phosphomevalonate kinase (PMK) polypeptides phosphorylates mevalonate-5-phosphate to form mevalonate-5-diphosphate. Standard methods (such as those described herein) can be used to determine whether a polypeptide has PMK polypeptide activity by measuring the ability of the polypeptide to convert mevalonate-5-phosphate into mevalonate-5-diphosphate *in vitro*, in a cell extract, or *in vivo*.

[0317] Diphosphomevalonate decarboxylase (MVD or DPMDC) polypeptides convert mevalonate-5-diphosphate into isopentenyl diphosphate (IPP). Standard methods (such as those described herein) can be used to determine whether a polypeptide has MVD polypeptide activity by measuring the ability of the polypeptide to convert mevalonate-5-diphosphate into IPP *in vitro*, in a cell extract, or *in vivo*.

[0318] Phosphomevalonate decarboxylase (PMDC) polypeptides convert mevalonate-5-phosphate into isopentenyl phosphate (IP). Standard methods (such as those described herein) can be used to determine whether a polypeptide has PMDC polypeptide activity by measuring the ability of the polypeptide to convert mevalonate-5-phosphate into IP *in vitro*, in a cell extract, or *in vivo*.

[0319] Isopentenyl phosphate kinase (IPK) polypeptides phosphorylate isopentenyl phosphate (IP) to form isopentenyl diphosphate (IPP). Standard methods (such as those described

herein) can be used to determine whether a polypeptide has IPK polypeptide activity by measuring the ability of the polypeptide to convert IP into IPP *in vitro*, in a cell extract, or *in vivo*.

[0320] Exemplary IDI polypeptides and nucleic acids are described above.

Exemplary Methods for Isolating Nucleic Acids

[0321] Isoprene synthase, efe, DXS, IDI, and/or MVA pathway nucleic acids can be isolated using standard methods. Methods of obtaining desired nucleic acids from a source organism of interest (such as a bacterial genome) are common and well known in the art of molecular biology (*see*, for example, WO 2004/033646 and references cited therein, which are each hereby incorporated by reference in their entireties, particularly with respect to the isolation of nucleic acids of interest). For example, if the sequence of the nucleic acid is known (such as any of the known nucleic acids described herein), suitable genomic libraries may be created by restriction endonuclease digestion and may be screened with probes complementary to the desired nucleic acid sequence. Once the sequence is isolated, the DNA may be amplified using standard primer directed amplification methods such as polymerase chain reaction (PCR) (U.S. Patent No. 4,683,202, which is incorporated by reference in its entirety, particularly with respect to PCR methods) to obtain amounts of DNA suitable for transformation using appropriate vectors.

[0322] Alternatively, isoprene synthase, efe, DXS, IDI, and/or MVA pathway nucleic acids (such as any isoprene synthase, efe, DXS, IDI, and/or MVA pathway nucleic acids with a known nucleic acid sequence) can be chemically synthesized using standard methods.

[0323] Additional isoprene synthase, efe, DXS, IDI, or MVA pathway polypeptides and nucleic acids which may be suitable for use in the compositions and methods described herein can be identified using standard methods. For example, cosmid libraries of the chromosomal DNA of organisms known to produce isoprene naturally can be constructed in organisms such as *E. coli*, and then screened for isoprene production. In particular, cosmid libraries may be created where large segments of genomic DNA (35-45 kb) are packaged into vectors and used to transform appropriate hosts. Cosmid vectors are unique in being able to accommodate large quantities of DNA. Generally cosmid vectors have at least one copy of the cos DNA sequence which is needed for packaging and subsequent circularization of the heterologous DNA. In addition to the cos sequence, these vectors

also contain an origin of replication such as ColEI and drug resistance markers such as a nucleic acid resistant to ampicillin or neomycin. Methods of using cosmid vectors for the transformation of suitable bacterial hosts are well described in Sambrook *et al.*, Molecular Cloning: A Laboratory Manual, 2nd ed., Cold Spring Harbor, 1989, which is hereby incorporated by reference in its entirety, particularly with respect to transformation methods.

[0324] Typically to clone cosmids, heterologous DNA is isolated using the appropriate restriction endonucleases and ligated adjacent to the cos region of the cosmid vector using the appropriate ligases. Cosmid vectors containing the linearized heterologous DNA are then reacted with a DNA packaging vehicle such as bacteriophage. During the packaging process, the cos sites are cleaved and the heterologous DNA is packaged into the head portion of the bacterial viral particle. These particles are then used to transfect suitable host cells such as *E. coli*. Once injected into the cell, the heterologous DNA circularizes under the influence of the cos sticky ends. In this manner, large segments of heterologous DNA can be introduced and expressed in host cells.

[0325] Additional methods for obtaining isoprene synthase, efe, DXS, IDI, and/or MVA pathway nucleic acids include screening a metagenomic library by assay (such as the headspace assay described herein) or by PCR using primers directed against nucleotides encoding for a length of conserved amino acids (for example, at least 3 conserved amino acids). Conserved amino acids can be identified by aligning amino acid sequences of known isoprene synthase, efe, DXS, IDI, and/or MVA pathway polypeptides. Conserved amino acids for isoprene synthase polypeptides can be identified based on aligned sequences of known isoprene synthase polypeptides. An organism found to produce isoprene naturally can be subjected to standard protein purification methods (which are well known in the art) and the resulting purified polypeptide can be sequenced using standard methods. Other methods are found in the literature (*see*, for example, Julsing *et al.*, *Applied. Microbiol. Biotechnol.* 75: 1377-84, 2007; Withers *et al.*, *Appl Environ Microbiol.* 73(19):6277-83, 2007, which are each hereby incorporated by reference in their entireties, particularly with respect to identification of nucleic acids involved in the synthesis of isoprene).

[0326] Additionally, standard sequence alignment and/or structure prediction programs can be used to identify additional DXS, IDI, or MVA pathway polypeptides and nucleic acids

based on the similarity of their primary and/or predicted polypeptide secondary structure with that of known DXS, IDI, or MVA pathway polypeptides and nucleic acids. Standard databases such as the swissprot-trembl database (world-wide web at “expasy.org”, Swiss Institute of Bioinformatics Swiss-Prot group CMU - 1 rue Michel Servet CH-1211 Geneva 4, Switzerland) can also be used to identify isoprene synthase, efe, DXS, IDI, or MVA pathway polypeptides and nucleic acids. The secondary and/or tertiary structure of an isoprene synthase, efe, DXS, IDI, or MVA pathway polypeptide can be predicted using the default settings of standard structure prediction programs, such as PredictProtein (630 West, 168 Street, BB217, New York, N.Y. 10032, USA). Alternatively, the actual secondary and/or tertiary structure of an isoprene synthase, efe, DXS, IDI, or MVA pathway polypeptide can be determined using standard methods. Additional isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acids can also be identified by hybridization to probes generated from known isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acids.

Exemplary Promoters and Vectors

[0327] Any of the isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid described herein can be included in one or more vectors. Accordingly, the invention also features vectors with one more nucleic acids encoding any of the isoprene synthase, efe, DXS, IDI, or MVA pathway polypeptides that are described herein. As used herein, a “vector” means a construct that is capable of delivering, and desirably expressing one or more nucleic acids of interest in a host cell. Examples of vectors include, but are not limited to, plasmids, viral vectors, DNA or RNA expression vectors, cosmids, and phage vectors. In some embodiments, the vector contains a nucleic acid under the control of an expression control sequence.

[0328] As used herein, an “expression control sequence” means a nucleic acid sequence that directs transcription of a nucleic acid of interest. An expression control sequence can be a promoter, such as a constitutive or an inducible promoter, or an enhancer. An “inducible promoter” is a promoter that is active under environmental or developmental regulation. The expression control sequence is operably linked to the nucleic acid segment to be transcribed.

[0329] In some embodiments, the vector contains a selective marker. The term “selective marker” refers to a nucleic acid capable of expression in a host cell that allows for ease of selection of those host cells containing an introduced nucleic acid or vector. Examples of selectable markers include, but are not limited to, antibiotic resistance nucleic acids (*e.g.*, kanamycin, ampicillin, carbenicillin, gentamicin, hygromycin, phleomycin, bleomycin, neomycin, or chloramphenicol) and/or nucleic acids that confer a metabolic advantage, such as a nutritional advantage on the host cell. Exemplary nutritional selective markers include those markers known in the art as *amdS*, *argB*, and *pyr4*. Markers useful in vector systems for transformation of *Trichoderma* are known in the art (*see, e.g.*, Finkelstein, Chapter 6 in *Biotechnology of Filamentous Fungi*, Finkelstein *et al.*, Eds. Butterworth-Heinemann, Boston, MA, Chap. 6., 1992; and Kinghorn *et al.*, *Applied Molecular Genetics of Filamentous Fungi*, Blackie Academic and Professional, Chapman and Hall, London, 1992, which are each hereby incorporated by reference in their entireties, particularly with respect to selective markers). In some embodiments, the selective marker is the *amdS* nucleic acid, which encodes the enzyme acetamidase, allowing transformed cells to grow on acetamide as a nitrogen source. The use of an *A. nidulans amdS* nucleic acid as a selective marker is described in Kelley *et al.*, *EMBO J.* 4:475 – 479, 1985 and Penttila *et al.*, *Gene* 61:155-164, 1987 (which are each hereby incorporated by reference in their entireties, particularly with respect to selective markers). In some embodiments, an isoprene synthase, *efe*, DXS, IDI, or MVA pathway nucleic acid integrates into a chromosome of the cells without a selective marker.

[0330] Suitable vectors are those which are compatible with the host cell employed. Suitable vectors can be derived, for example, from a bacterium, a virus (such as bacteriophage T7 or a M-13 derived phage), a cosmid, a yeast, or a plant. Protocols for obtaining and using such vectors are known to those in the art (*see, for example*, Sambrook *et al.*, *Molecular Cloning: A Laboratory Manual*, 2nd ed., Cold Spring Harbor, 1989, which is hereby incorporated by reference in its entirety, particularly with respect to the use of vectors).

[0331] Promoters are well known in the art. Any promoter that functions in the host cell can be used for expression of an isoprene synthase, *efe*, DXS, IDI, or MVA pathway nucleic acid in the host cell. Initiation control regions or promoters, which are useful to drive expression of isoprene synthase, *efe*, DXS, IDI, or MVA pathway nucleic acids in various host cells are numerous and familiar to those skilled in the art (*see, for example*, WO

2004/033646 and references cited therein, which are each hereby incorporated by reference in their entireties, particularly with respect to vectors for the expression of nucleic acids of interest). Virtually any promoter capable of driving these nucleic acids is suitable for the present invention including, but not limited to, CYC1, HIS3, GAL1, GAL10, ADH1, PGK, PHO5, GAPDH, ADCl, TRP1, URA3, LEU2, ENO, and TPI (useful for expression in *Saccharomyces*); AOX1 (useful for expression in *Pichia*); and ffh, lac, trp, λ P_L, λ P_R, T7, tac, and trc (useful for expression in *E. coli*).

[0332] In some embodiments, a glucose isomerase promoter is used (*see*, for example, U.S. Patent No. 7,132,527 and references cited therein, which are each hereby incorporated by reference in their entireties, particularly with respect promoters and plasmid systems for expressing polypeptides of interest). Reported glucose isomerase promoter mutants can be used to vary the level of expression of the polypeptide encoded by a nucleic acid operably linked to the glucose isomerase promoter (U.S. Patent No. 7,132,527). In various embodiments, the glucose isomerase promoter is contained in a low, medium, or high copy plasmid (U.S. Patent No. 7,132,527).

[0333] In various embodiments, an isoprene synthase, efe, DXS, IDI, and/or MVA pathway nucleic acid is contained in a low copy plasmid (*e.g.*, a plasmid that is maintained at about 1 to about 4 copies per cell), medium copy plasmid (*e.g.*, a plasmid that is maintained at about 10 to about 15 copies per cell), or high copy plasmid (*e.g.*, a plasmid that is maintained at about 50 or more copies per cell). In some embodiments, the heterologous or extra endogenous isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid is operably linked to a T7 promoter. In some embodiments, the heterologous or extra endogenous isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid operably linked to a T7 promoter is contained in a medium or high copy plasmid. In some embodiments, the heterologous or extra endogenous isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid is operably linked to a Trc promoter. In some embodiments, the heterologous or extra endogenous isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid operably linked to a Trc promoter is contained in a medium or high copy plasmid. In some embodiments, the heterologous or extra endogenous isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid is operably linked to a Lac promoter. In some embodiments, the heterologous or extra endogenous isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid operably linked to a Lac promoter is contained in a low

copy plasmid. In some embodiments, the heterologous or extra endogenous isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid is operably linked to an endogenous promoter, such as an endogenous *Escherichia*, *Pantoea*, *Bacillus*, *Yarrowia*, *Streptomyces*, or *Trichoderma* promoter or an endogenous alkaline serine protease, isoprene synthase, efe, DXS, IDI, or MVA pathway promoter. In some embodiments, the heterologous or extra endogenous isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid operably linked to an endogenous promoter is contained in a high copy plasmid. In some embodiments, the vector is a replicating plasmid that does not integrate into a chromosome in the cells. In some embodiments, part or all of the vector integrates into a chromosome in the cells.

[0334] In some embodiments, the vector is any vector which when introduced into a fungal host cell is integrated into the host cell genome and is replicated. Reference is made to the Fungal Genetics Stock Center Catalogue of Strains (FGSC, the world-wide web at “fgsc.net” and the references cited therein, which are each hereby incorporated by reference in their entireties, particularly with respect to vectors) for a list of vectors. Additional examples of suitable expression and/or integration vectors are provided in Sambrook *et al.*, Molecular Cloning: A Laboratory Manual, 2nd ed., Cold Spring Harbor, 1989, Current Protocols in Molecular Biology (F. M. Ausubel *et al.* (eds) 1987, Supplement 30, section 7.7.18); van den Hondel *et al.* in Bennett and Lasure (Eds.) More Gene Manipulations in Fungi, Academic Press pp. 396-428, 1991; and U.S. Patent No. 5,874,276, which are each hereby incorporated by reference in their entireties, particularly with respect to vectors. Particularly useful vectors include pFB6, pBR322, PUC18, pUC100, and pENTR/D.

[0335] In some embodiments, an isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid is operably linked to a suitable promoter that shows transcriptional activity in a fungal host cell. The promoter may be derived from one or more nucleic acids encoding a polypeptide that is either endogenous or heterologous to the host cell. In some embodiments, the promoter is useful in a *Trichoderma* host. Suitable non-limiting examples of promoters include *cbh1*, *cbh2*, *egl1*, *egl2*, *pepA*, *hfb1*, *hfb2*, *xyn1*, and *amy*. In some embodiments, the promoter is one that is native to the host cell. For example, in some embodiments when *T. reesei* is the host, the promoter is a native *T. reesei* promoter. In some embodiments, the promoter is *T. reesei cbh1*, which is an inducible promoter and

has been deposited in GenBank under Accession No. D86235, which is incorporated by reference in its entirety, particularly with respect to promoters. In some embodiments, the promoter is one that is heterologous to the fungal host cell. Other examples of useful promoters include promoters from the genes of *A. awamori* and *A. niger* glucoamylase (glaA) (Nunberg *et al.*, *Mol. Cell Biol.* 4:2306-2315, 1984 and Boel *et al.*, *EMBO J.* 3:1581-1585, 1984, which are each hereby incorporated by reference in their entireties, particularly with respect to promoters); *Aspergillus niger* alpha amylases, *Aspergillus oryzae* TAKA amylase, *T. reesei xln1*, and the *T. reesei cellobiohydrolase 1* (EP 137280, which is incorporated by reference in its entirety, particularly with respect to promoters).

[0336] In some embodiments, the expression vector also includes a termination sequence. Termination control regions may also be derived from various genes native to the host cell. In some embodiments, the termination sequence and the promoter sequence are derived from the same source. In another embodiment, the termination sequence is endogenous to the host cell. A particularly suitable terminator sequence is *cbh1* derived from a *Trichoderma* strain (such as *T. reesei*). Other useful fungal terminators include the terminator from an *A. niger* or *A. awamori* glucoamylase nucleic acid (Nunberg *et al.*, *Mol. Cell Biol.* 4:2306-2315, 1984 and Boel *et al.*, *EMBO J.* 3:1581-1585, 1984; which are each hereby incorporated by reference in their entireties, particularly with respect to fungal terminators). Optionally, a termination site may be included. For effective expression of the polypeptides, DNA encoding the polypeptide are linked operably through initiation codons to selected expression control regions such that expression results in the formation of the appropriate messenger RNA.

[0337] In some embodiments, the promoter, coding, region, and terminator all originate from the isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid to be expressed. In some embodiments, the coding region for an isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid is inserted into a general-purpose expression vector such that it is under the transcriptional control of the expression construct promoter and terminator sequences. In some embodiments, genes or part thereof are inserted downstream of the strong *cbh1* promoter.

[0338] An isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid can be incorporated into a vector, such as an expression vector, using standard techniques (Sambrook *et al.*, *Molecular Cloning: A Laboratory Manual*, Cold Spring Harbor, 1982,

which is hereby incorporated by reference in its entirety, particularly with respect to the screening of appropriate DNA sequences and the construction of vectors). Methods used to ligate the DNA construct comprising a nucleic acid of interest (such as an isoprene synthase, *efe*, DXS, IDI, or MVA pathway nucleic acid), a promoter, a terminator, and other sequences and to insert them into a suitable vector are well known in the art. For example, restriction enzymes can be used to cleave the isoprene synthase, *efe*, DXS, IDI, or MVA pathway nucleic acid and the vector. Then, the compatible ends of the cleaved isoprene synthase, *efe*, DXS, IDI, or MVA pathway nucleic acid and the cleaved vector can be ligated. Linking is generally accomplished by ligation at convenient restriction sites. If such sites do not exist, the synthetic oligonucleotide linkers are used in accordance with conventional practice (*see*, Sambrook *et al.*, Molecular Cloning: A Laboratory Manual, 2nd ed., Cold Spring Harbor, 1989, and Bennett and Lasure, More Gene Manipulations in Fungi, Academic Press, San Diego, pp 70–76, 1991, which are each hereby incorporated by reference in their entireties, particularly with respect to oligonucleotide linkers). Additionally, vectors can be constructed using known recombination techniques (*e.g.*, Invitrogen Life Technologies, Gateway Technology).

[0339] In some embodiments, it may be desirable to over-express isoprene synthase, *efe*, DXS, IDI, or MVA pathway nucleic acids at levels far higher than currently found in naturally-occurring cells. This result may be accomplished by the selective cloning of the nucleic acids encoding those polypeptides into multicopy plasmids or placing those nucleic acids under a strong inducible or constitutive promoter. Methods for over-expressing desired polypeptides are common and well known in the art of molecular biology and examples may be found in Sambrook *et al.*, Molecular Cloning: A Laboratory Manual, 2nd ed., Cold Spring Harbor, 1989, which is hereby incorporated by reference in its entirety, particularly with respect to cloning techniques.

[0340] The following resources include descriptions of additional general methodology useful in accordance with the invention: Kreigler, Gene Transfer and Expression; A Laboratory Manual, 1990 and Ausubel *et al.*, Eds. Current Protocols in Molecular Biology, 1994, which are each hereby incorporated by reference in their entireties, particularly with respect to molecular biology and cloning techniques.

Exemplary Source Organisms

[0341] Isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acids (and their encoded polypeptides) can be obtained from any organism that naturally contains isoprene synthase, efe, DXS, IDI, and/or MVA pathway nucleic acids. As noted above, isoprene is formed naturally by a variety of organisms, such as bacteria, yeast, plants, and animals. Organisms contain the MVA pathway, DXP pathway, or both the MVA and DXP pathways for producing isoprene (Figures 19A and 19B). Thus, DXS nucleic acids can be obtained, *e.g.*, from any organism that contains the DXP pathway or contains both the MVA and DXP pathways. IDI and isoprene synthase nucleic acids can be obtained, *e.g.*, from any organism that contains the MVA pathway, DXP pathway, or both the MVA and DXP pathways. MVA pathway nucleic acids can be obtained, *e.g.*, from any organism that contains the MVA pathway or contains both the MVA and DXP pathways.

[0342] In some embodiments, the nucleic acid sequence of the isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid is identical to the sequence of a nucleic acid that is produced by any of the following organisms in nature. In some embodiments, the amino acid sequence of the isoprene synthase, efe, DXS, IDI, or MVA pathway polypeptide is identical to the sequence of a polypeptide that is produced by any of the following organisms in nature. In some embodiments, the isoprene synthase, efe, DXS, IDI, or MVA pathway nucleic acid or polypeptide is a mutant nucleic acid or polypeptide derived from any of the organisms described herein. As used herein, “derived from” refers to the source of the nucleic acid or polypeptide into which one or more mutations is introduced. For example, a polypeptide that is “derived from a plant polypeptide” refers to polypeptide of interest that results from introducing one or more mutations into the sequence of a wild-type (*i.e.*, a sequence occurring in nature) plant polypeptide.

[0343] In some embodiments, the source organism is a fungus, examples of which are species of *Aspergillus* such as *A. oryzae* and *A. niger*, species of *Saccharomyces* such as *S. cerevisiae*, species of *Schizosaccharomyces* such as *S. pombe*, and species of *Trichoderma* such as *T. reesei*. In some embodiments, the source organism is a filamentous fungal cell. The term “filamentous fungi” refers to all filamentous forms of the subdivision Eumycotina (*see*, Alexopoulos, C. J. (1962), *Introductory Mycology*, Wiley, New York). These fungi are characterized by a vegetative mycelium with a cell wall composed of chitin, cellulose, and other complex polysaccharides. The filamentous fungi are

morphologically, physiologically, and genetically distinct from yeasts. Vegetative growth by filamentous fungi is by hyphal elongation and carbon catabolism is obligatory aerobic. The filamentous fungal parent cell may be a cell of a species of, but not limited to, *Trichoderma*, (e.g., *Trichoderma reesei*, the asexual morph of *Hypocrea jecorina*, previously classified as *T. longibrachiatum*, *Trichoderma viride*, *Trichoderma koningii*, *Trichoderma harzianum*) (Sheir-Neirs *et al.*, Appl. Microbiol. Biotechnol 20: 46-53, 1984; ATCC No. 56765 and ATCC No. 26921); *Penicillium sp.*, *Humicola sp.* (e.g., *H. insolens*, *H. lanuginosa*, or *H. grisea*); *Chrysosporium sp.* (e.g., *C. lucknowense*), *Gliocladium sp.*, *Aspergillus sp.* (e.g., *A. oryzae*, *A. niger*, *A. sojae*, *A. japonicus*, *A. nidulans*, or *A. awamori*) (Ward *et al.*, Appl. Microbiol. Biotechnol. 39: 7380743, 1993 and Goedegebuur *et al.*, Genet 41: 89-98, 2002), *Fusarium sp.*, (e.g., *F. roseum*, *F. gramineum*, *F. cerealis*, *F. oxysporum*, or *F. venenatum*), *Neurospora sp.*, (e.g., *N. crassa*), *Hypocrea sp.*, *Mucor sp.*, (e.g., *M. miehei*), *Rhizopus sp.* and *Emmericella sp.* (see also, Innis *et al.*, Sci. 228: 21-26, 1985). The term “*Trichoderma*” or “*Trichoderma sp.*” or “*Trichoderma spp.*” refer to any fungal genus previously or currently classified as *Trichoderma*.

[0344] In some embodiments, the fungus is *A. nidulans*, *A. awamori*, *A. oryzae*, *A. aculeatus*, *A. niger*, *A. japonicus*, *T. reesei*, *T. viride*, *F. oxysporum*, or *F. solani*. *Aspergillus* strains are disclosed in Ward *et al.*, Appl. Microbiol. Biotechnol. 39:738-743, 1993 and Goedegebuur *et al.*, Curr Gene 41:89-98, 2002, which are each hereby incorporated by reference in their entireties, particularly with respect to fungi. In particular embodiments, the fungus is a strain of *Trichoderma*, such as a strain of *T. reesei*. Strains of *T. reesei* are known and non-limiting examples include ATCC No. 13631, ATCC No. 26921, ATCC No. 56764, ATCC No. 56765, ATCC No. 56767, and NRRL 15709, which are each hereby incorporated by reference in their entireties, particularly with respect to strains of *T. reesei*. In some embodiments, the host strain is a derivative of RL-P37. RL-P37 is disclosed in Sheir-Neiss *et al.*, Appl. Microbiol. Biotechnology 20:46–53, 1984, which is hereby incorporated by reference in its entirety, particularly with respect to strains of *T. reesei*.

[0345] In some embodiments, the source organism is a yeast, such as *Saccharomyces sp.*, *Schizosaccharomyces sp.*, *Pichia sp.*, or *Candida sp.* In some embodiments, the *Saccharomyces sp.* is *Saccharomyces cerevisiae*.

[0346] In some embodiments, the source organism is a bacterium, such as strains of *Bacillus* such as *B. lichenformis* or *B. subtilis*, strains of *Pantoea* such as *P. citrea*, strains of *Pseudomonas* such as *P. alcaligenes*, *P. putida*, *P. syringae*, or *P. fluorescens*, strains of *Streptomyces* such as *S. lividans* or *S. rubiginosus*, strains of *Corynebacterium* sp. such as *Corynebacterium glutamicum*, strains of *Rhodopseudomonas* sp. such as *Rhodopseudomonas palustris*, or strains of *Escherichia* such as *E. coli*.

[0347] As used herein, “the genus *Bacillus*” includes all species within the genus “*Bacillus*,” as known to those of skill in the art, including but not limited to *B. subtilis*, *B. licheniformis*, *B. lentus*, *B. brevis*, *B. stearothermophilus*, *B. alkalophilus*, *B. amyloliquefaciens*, *B. clausii*, *B. halodurans*, *B. megaterium*, *B. coagulans*, *B. circulans*, *B. lautus*, and *B. thuringiensis*. It is recognized that the genus *Bacillus* continues to undergo taxonomical reorganization. Thus, it is intended that the genus include species that have been reclassified, including but not limited to such organisms as *B. stearothermophilus*, which is now named “*Geobacillus stearothermophilus*.” The production of resistant endospores in the presence of oxygen is considered the defining feature of the genus *Bacillus*, although this characteristic also applies to the recently named *Alicyclobacillus*, *Amphibacillus*, *Aneurinibacillus*, *Anoxybacillus*, *Brevibacillus*, *Filobacillus*, *Gracilibacillus*, *Halobacillus*, *Paenibacillus*, *Salibacillus*, *Thermobacillus*, *Ureibacillus*, and *Virgibacillus*.

[0348] In some embodiments, the source organism is a gram-positive bacterium. Non-limiting examples include strains of *Streptomyces* (e.g., *S. lividans*, *S. coelicolor*, or *S. griseus*) and *Bacillus*. In some embodiments, the source organism is a gram-negative bacterium, such as *E. coli*, *Rhodopseudomonas* sp. such as *Rhodopseudomonas palustris*, or *Pseudomonas* sp., such as *P. alcaligenes*, *P. putida*, *P. syringae*, or *P. fluorescens*.

[0349] In some embodiments, the source organism is a plant, such as a plant from the family Fabaceae, such as the Faboideae subfamily. In some embodiments, the source organism is kudzu, poplar (such as *Populus alba x tremula* CAC35696), aspen (such as *Populus tremuloides*), or *Quercus robur*.

[0350] In some embodiments, the source organism is an algae, such as a green algae, red algae, glaucophytes, chlorarachniophytes, euglenids, chromista, or dinoflagellates.

[0351] In some embodiments, the source organism is a cyanobacteria, such as cyanobacteria classified into any of the following groups based on morphology: *Chroococcales*, *Pleurocapsales*, *Oscillatoriales*, *Nostocales*, or *Stigonematales*.

Exemplary Host Cells

[0352] A variety of host cells can be used to express isoprene synthase, efe, DXS, IDI, and/or MVA pathway polypeptides and to produce isoprene in the methods of the claimed invention. Exemplary host cells include cells from any of the organisms listed in the prior section under the heading “*Exemplary Source Organisms*.” The host cell may be a cell that naturally produces isoprene or ethylene or a cell that does not naturally produce isoprene or ethylene. In some embodiments, the host cell naturally produces isoprene using the DXP pathway, and an isoprene synthase, DXS, and/or IDI nucleic acid is added to enhance production of isoprene using this pathway. In some embodiments, the host cell naturally produces isoprene using the MVA pathway, and an isoprene synthase and/or one or more MVA pathway nucleic acids are added to enhance production of isoprene using this pathway. In some embodiments, the host cell naturally produces isoprene using the DXP pathway and one or more MVA pathway nucleic acids are added to produce isoprene using part or all of the MVA pathway as well as the DXP pathway. In some embodiments, the host cell naturally produces isoprene using both the DXP and MVA pathways and one or more isoprene synthase, DXS, IDI, or MVA pathway nucleic acids are added to enhance production of isoprene by one or both of these pathways. In some embodiments, the host cell naturally produces ethylene, and an efe nucleic acid is added to enhance production of ethylene.

Exemplary Transformation Methods

[0353] Isoprene synthase, efe, DXS, IDI, and/or MVA pathway nucleic acids or vectors containing them can be inserted into a host cell (*e.g.*, a plant cell, a fungal cell, a yeast cell, or a bacterial cell described herein) using standard techniques for expression of the encoded isoprene synthase, efe, DXS, IDI, and/or MVA pathway polypeptide. Introduction of a DNA construct or vector into a host cell can be performed using techniques such as transformation, electroporation, nuclear microinjection, transduction, transfection (*e.g.*, lipofection mediated or DEAE-Dextrin mediated transfection or transfection using a recombinant phage virus), incubation with calcium phosphate DNA

precipitate, high velocity bombardment with DNA-coated microprojectiles, and protoplast fusion. General transformation techniques are known in the art (*see, e.g.,* Current Protocols in Molecular Biology (F. M. Ausubel *et al.* (eds) Chapter 9, 1987; Sambrook *et al.*, Molecular Cloning: A Laboratory Manual, 2nd ed., Cold Spring Harbor, 1989; and Campbell *et al.*, *Curr. Genet.* 16:53-56, 1989, which are each hereby incorporated by reference in their entirety, particularly with respect to transformation methods). The expression of heterologous polypeptide in *Trichoderma* is described in U.S. Patent No. 6,022,725; U.S. Patent No. 6,268,328; U.S. Patent No. 7,262,041; WO 2005/001036; Harkki *et al.*; *Enzyme Microb. Technol.* 13:227-233, 1991; Harkki *et al.*, *Bio Technol.* 7:596-603, 1989; EP 244,234; EP 215,594; and Nevalainen *et al.*, “*The Molecular Biology of Trichoderma and its Application to the Expression of Both Homologous and Heterologous Genes,*” in Molecular Industrial Mycology, Eds. Leong and Berka, Marcel Dekker Inc., NY pp. 129 – 148, 1992, which are each hereby incorporated by reference in their entirety, particularly with respect to transformation and expression methods). Reference is also made to Cao *et al.*, (*Sci.* 9:991–1001, 2000; EP 238023; and Yelton *et al.*, *Proceedings. Natl. Acad. Sci. USA* 81:1470-1474, 1984 (which are each hereby incorporated by reference in their entirety, particularly with respect to transformation methods) for transformation of *Aspergillus* strains. The introduced nucleic acids may be integrated into chromosomal DNA or maintained as extrachromosomal replicating sequences.

[0354] Any method known in the art may be used to select transformants. In one non-limiting example, stable transformants including an *amdS* marker are distinguished from unstable transformants by their faster growth rate and the formation of circular colonies with a smooth, rather than ragged outline on solid culture medium containing acetamide. Additionally, in some cases a further test of stability is conducted by growing the transformants on a solid non-selective medium (*e.g.,* a medium that lacks acetamide), harvesting spores from this culture medium, and determining the percentage of these spores which subsequently germinate and grow on selective medium containing acetamide.

[0355] In some embodiments, fungal cells are transformed by a process involving protoplast formation and transformation of the protoplasts followed by regeneration of the cell wall in a known manner. In one specific embodiment, the preparation of *Trichoderma sp.* for

transformation involves the preparation of protoplasts from fungal mycelia (*see*, Campbell *et al.*, *Curr. Genet.* 16:53-56, 1989, which is incorporated by reference in its entirety, particularly with respect to transformation methods). In some embodiments, the mycelia are obtained from germinated vegetative spores. The mycelia are treated with an enzyme that digests the cell wall resulting in protoplasts. The protoplasts are then protected by the presence of an osmotic stabilizer in the suspending medium. These stabilizers include sorbitol, mannitol, potassium chloride, magnesium sulfate, and the like. Usually the concentration of these stabilizers varies between 0.8 M and 1.2 M. It is desirable to use about a 1.2 M solution of sorbitol in the suspension medium.

[0356] Uptake of DNA into the host *Trichoderma sp.* strain is dependent upon the calcium ion concentration. Generally, between about 10 mM CaCl₂ and 50 mM CaCl₂ is used in an uptake solution. In addition to the calcium ion in the uptake solution, other compounds generally included are a buffering system such as TE buffer (10 mM Tris, pH 7.4; 1 mM EDTA) or 10 mM MOPS, pH 6.0 buffer (morpholinepropanesulfonic acid) and polyethylene glycol (PEG). While not intending to be bound to any particular theory, it is believed that the polyethylene glycol acts to fuse the cell membranes, thus permitting the contents of the medium to be delivered into the cytoplasm of the *Trichoderma sp.* strain and the plasmid DNA to be transferred to the nucleus. This fusion frequently leaves multiple copies of the plasmid DNA integrated into the host chromosome.

[0357] Usually a suspension containing the *Trichoderma sp.* protoplasts or cells that have been subjected to a permeability treatment at a density of 10⁵ to 10⁷/mL (such as 2 x 10⁶/mL) are used in the transformation. A volume of 100 µL of these protoplasts or cells in an appropriate solution (*e.g.*, 1.2 M sorbitol and 50 mM CaCl₂) are mixed with the desired DNA. Generally, a high concentration of PEG is added to the uptake solution. From 0.1 to 1 volume of 25% PEG 4000 can be added to the protoplast suspension. In some embodiments, about 0.25 volumes are added to the protoplast suspension. Additives such as dimethyl sulfoxide, heparin, spermidine, potassium chloride, and the like may also be added to the uptake solution and aid in transformation. Similar procedures are available for other fungal host cells (*see, e.g.*, U.S. Patent Nos. 6,022,725 and 6,268,328, which are each hereby incorporated by reference in their entireties, particularly with respect to transformation methods).

[0358] Generally, the mixture is then cultured at approximately 0°C for a period of between 10 to 30 minutes. Additional PEG is then added to the mixture to further enhance the uptake of the desired nucleic acid sequence. The 25% PEG 4000 is generally added in volumes of 5 to 15 times the volume of the transformation mixture; however, greater and lesser volumes may be suitable. The 25% PEG 4000 is desirably about 10 times the volume of the transformation mixture. After the PEG is added, the transformation mixture is then cultured either at room temperature or on ice before the addition of a sorbitol and CaCl₂ solution. The protoplast suspension is then further added to molten aliquots of a growth medium. When the growth medium includes a growth selection (*e.g.*, acetamide or an antibiotic) it permits the growth of transformants only.

[0359] The transformation of bacterial cells may be performed according to conventional methods, *e.g.*, as described in Sambrook *et al.*, Molecular Cloning: A Laboratory Manual, Cold Spring Harbor, 1982, which is hereby incorporated by reference in its entirety, particularly with respect to transformation methods.

Exemplary Cell Culture Media

[0360] The invention also includes a cell or a population of cells in culture that produce isoprene or ethylene. By “cells in culture” is meant two or more cells in a solution (*e.g.*, a cell medium) that allows the cells to undergo one or more cell divisions. “Cells in culture” do not include plant cells that are part of a living, multicellular plant containing cells that have differentiated into plant tissues. In various embodiments, the cell culture includes at least or about 10, 20, 50, 100, 200, 500, 1,000, 5,000, 10,000 or more cells.

[0361] Any carbon source can be used to cultivate the host cells. The term “carbon source” refers to one or more carbon-containing compounds capable of being metabolized by a host cell or organism. For example, the cell medium used to cultivate the host cells may include any carbon source suitable for maintaining the viability or growing the host cells.

[0362] In some embodiments, the carbon source is a carbohydrate (such as monosaccharide, disaccharide, oligosaccharide, or polysaccharides), invert sugar (*e.g.*, enzymatically treated sucrose syrup), glycerol, glycerine (*e.g.*, a glycerine byproduct of a biodiesel or soap-making process), dihydroxyacetone, one-carbon source, oil (*e.g.*, a plant or vegetable oil such as corn, palm, or soybean oil), animal fat, animal oil, fatty acid (*e.g.*, a saturated fatty acid, unsaturated fatty acid, or polyunsaturated fatty acid), lipid, phospholipid,

glycerolipid, monoglyceride, diglyceride, triglyceride, polypeptide (*e.g.*, a microbial or plant protein or peptide), renewable carbon source (*e.g.*, a biomass carbon source such as a hydrolyzed biomass carbon source), yeast extract, component from a yeast extract, polymer, acid, alcohol, aldehyde, ketone, amino acid, succinate, lactate, acetate, ethanol, or any combination of two or more of the foregoing. In some embodiments, the carbon source is a product of photosynthesis, including, but not limited to, glucose.

[0363] Exemplary monosaccharides include glucose and fructose; exemplary oligosaccharides include lactose and sucrose, and exemplary polysaccharides include starch and cellulose. Exemplary carbohydrates include C6 sugars (*e.g.*, fructose, mannose, galactose, or glucose) and C5 sugars (*e.g.*, xylose or arabinose). In some embodiments, the cell medium includes a carbohydrate as well as a carbon source other than a carbohydrate (*e.g.*, glycerol, glycerine, dihydroxyacetone, one-carbon source, oil, animal fat, animal oil, fatty acid, lipid, phospholipid, glycerolipid, monoglyceride, diglyceride, triglyceride, renewable carbon source, or a component from a yeast extract). In some embodiments, the cell medium includes a carbohydrate as well as a polypeptide (*e.g.*, a microbial or plant protein or peptide). In some embodiments, the microbial polypeptide is a polypeptide from yeast or bacteria. In some embodiments, the plant polypeptide is a polypeptide from soy, corn, canola, jatropha, palm, peanut, sunflower, coconut, mustard, rapeseed, cottonseed, palm kernel, olive, safflower, sesame, or linseed.

[0364] In some embodiments, the concentration of the carbohydrate is at least or about 5 grams per liter of broth (g/L, wherein the volume of broth includes both the volume of the cell medium and the volume of the cells), such as at least or about 10, 15, 20, 30, 40, 50, 60, 80, 100, 150, 200, 300, 400, or more g/L. In some embodiments, the concentration of the carbohydrate is between about 50 and about 400 g/L, such as between about 100 and about 360 g/L, between about 120 and about 360 g/L, or between about 200 and about 300 g/L. In some embodiments, this concentration of carbohydrate includes the total amount of carbohydrate that is added before and/or during the culturing of the host cells.

[0365] In some embodiments, the cells are cultured under limited glucose conditions. By “limited glucose conditions” is meant that the amount of glucose that is added is less than or about 105% (such as about 100%) of the amount of glucose that is consumed by the cells. In particular embodiments, the amount of glucose that is added to the culture medium is approximately the same as the amount of glucose that is consumed by the cells

during a specific period of time. In some embodiments, the rate of cell growth is controlled by limiting the amount of added glucose such that the cells grow at the rate that can be supported by the amount of glucose in the cell medium. In some embodiments, glucose does not accumulate during the time the cells are cultured. In various embodiments, the cells are cultured under limited glucose conditions for greater than or about 1, 2, 3, 5, 10, 15, 20, 25, 30, 35, 40, 50, 60, or 70 hours. In various embodiments, the cells are cultured under limited glucose conditions for greater than or about 5, 10, 15, 20, 25, 30, 35, 40, 50, 60, 70, 80, 90, 95, or 100% of the total length of time the cells are cultured. While not intending to be bound by any particular theory, it is believed that limited glucose conditions may allow more favorable regulation of the cells.

[0366] In some embodiments, the cells are cultured in the presence of an excess of glucose.

In particular embodiments, the amount of glucose that is added is greater than about 105% (such as about or greater than 110, 120, 150, 175, 200, 250, 300, 400, or 500%) or more of the amount of glucose that is consumed by the cells during a specific period of time. In some embodiments, glucose accumulates during the time the cells are cultured.

[0367] Exemplary lipids are any substance containing one or more fatty acids that are C4 and above fatty acids that are saturated, unsaturated, or branched.

[0368] Exemplary oils are lipids that are liquid at room temperature. In some embodiments, the lipid contains one or more C4 or above fatty acids (*e.g.*, contains one or more saturated, unsaturated, or branched fatty acid with four or more carbons). In some embodiments, the oil is obtained from soy, corn, canola, jatropha, palm, peanut, sunflower, coconut, mustard, rapeseed, cottonseed, palm kernel, olive, safflower, sesame, linseed, oleagineous microbial cells, Chinese tallow, or any combination of two or more of the foregoing.

[0369] Exemplary fatty acids include compounds of the formula RCOOH, where “R” is a hydrocarbon. Exemplary unsaturated fatty acids include compounds where “R” includes at least one carbon-carbon double bond. Exemplary unsaturated fatty acids include, but are not limited to, oleic acid, vaccenic acid, linoleic acid, palmitelaidic acid, and arachidonic acid. Exemplary polyunsaturated fatty acids include compounds where “R” includes a plurality of carbon-carbon double bonds. Exemplary saturated fatty acids include compounds where “R” is a saturated aliphatic group. In some embodiments, the carbon source

includes one or more C₁₂-C₂₂ fatty acids, such as a C₁₂ saturated fatty acid, a C₁₄ saturated fatty acid, a C₁₆ saturated fatty acid, a C₁₈ saturated fatty acid, a C₂₀ saturated fatty acid, or a C₂₂ saturated fatty acid. In an exemplary embodiment, the fatty acid is palmitic acid. In some embodiments, the carbon source is a salt of a fatty acid (*e.g.*, an unsaturated fatty acid), a derivative of a fatty acid (*e.g.*, an unsaturated fatty acid), or a salt of a derivative of fatty acid (*e.g.*, an unsaturated fatty acid). Suitable salts include, but are not limited to, lithium salts, potassium salts, sodium salts, and the like. Di- and triglycerols are fatty acid esters of glycerol.

[0370] In some embodiments, the concentration of the lipid, oil, fat, fatty acid, monoglyceride, diglyceride, or triglyceride is at least or about 1 gram per liter of broth (g/L, wherein the volume of broth includes both the volume of the cell medium and the volume of the cells), such as at least or about 5, 10, 15, 20, 30, 40, 50, 60, 80, 100, 150, 200, 300, 400, or more g/L. In some embodiments, the concentration of the lipid, oil, fat, fatty acid, monoglyceride, diglyceride, or triglyceride is between about 10 and about 400 g/L, such as between about 25 and about 300 g/L, between about 60 and about 180 g/L, or between about 75 and about 150 g/L. In some embodiments, the concentration includes the total amount of the lipid, oil, fat, fatty acid, monoglyceride, diglyceride, or triglyceride that is added before and/or during the culturing of the host cells. In some embodiments, the carbon source includes both (i) a lipid, oil, fat, fatty acid, monoglyceride, diglyceride, or triglyceride and (ii) a carbohydrate, such as glucose. In some embodiments, the ratio of the lipid, oil, fat, fatty acid, monoglyceride, diglyceride, or triglyceride to the carbohydrate is about 1:1 on a carbon basis (*i.e.*, one carbon in the lipid, oil, fat, fatty acid, monoglyceride, diglyceride, or triglyceride per carbohydrate carbon). In particular embodiments, the amount of the lipid, oil, fat, fatty acid, monoglyceride, diglyceride, or triglyceride is between about 60 and 180 g/L, and the amount of the carbohydrate is between about 120 and 360 g/L.

[0371] Exemplary microbial polypeptide carbon sources include one or more polypeptides from yeast or bacteria. Exemplary plant polypeptide carbon sources include one or more polypeptides from soy, corn, canola, jatropha, palm, peanut, sunflower, coconut, mustard, rapeseed, cottonseed, palm kernel, olive, safflower, sesame, or linseed.

[0372] Exemplary renewable carbon sources include cheese whey permeate, cornsteep liquor, sugar beet molasses, barley malt, and components from any of the foregoing.

Exemplary renewable carbon sources also include glucose, hexose, pentose and xylose present in biomass, such as corn, switchgrass, sugar cane, cell waste of fermentation processes, and protein by-product from the milling of soy, corn, or wheat. In some embodiments, the biomass carbon source is a lignocellulosic, hemicellulosic, or cellulosic material such as, but are not limited to, a grass, wheat, wheat straw, bagasse, sugar cane bagasse, soft wood pulp, corn, corn cob or husk, corn kernel, fiber from corn kernels, corn stover, switch grass, rice hull product, or a by-product from wet or dry milling of grains (*e.g.*, corn, sorghum, rye, triticale, barley, wheat, and/or distillers grains). Exemplary cellulosic materials include wood, paper and pulp waste, herbaceous plants, and fruit pulp. In some embodiments, the carbon source includes any plant part, such as stems, grains, roots, or tubers. In some embodiments, all or part of any of the following plants are used as a carbon source: corn, wheat, rye, sorghum, triticale, rice, millet, barley, cassava, legumes, such as beans and peas, potatoes, sweet potatoes, bananas, sugarcane, and/or tapioca. In some embodiments, the carbon source is a biomass hydrolysate, such as a biomass hydrolysate that includes both xylose and glucose or that includes both sucrose and glucose.

[0373] In some embodiments, the renewable carbon source (such as biomass) is pretreated before it is added to the cell culture medium. In some embodiments, the pretreatment includes enzymatic pretreatment, chemical pretreatment, or a combination of both enzymatic and chemical pretreatment (*see*, for example, Farzaneh *et al.*, *Bioresource Technology* 96 (18): 2014-2018, 2005; U.S. Patent No. 6,176,176; U.S. Patent No. 6,106,888; which are each hereby incorporated by reference in their entireties, particularly with respect to the pretreatment of renewable carbon sources). In some embodiments, the renewable carbon source is partially or completely hydrolyzed before it is added to the cell culture medium.

[0374] In some embodiments, the renewable carbon source (such as corn stover) undergoes ammonia fiber expansion (AFEX) pretreatment before it is added to the cell culture medium (*see*, for example, Farzaneh *et al.*, *Bioresource Technology* 96 (18): 2014-2018, 2005). During AFEX pretreatment, a renewable carbon source is treated with liquid anhydrous ammonia at moderate temperatures (such as about 60 to about 100 °C) and high pressure (such as about 250 to about 300 psi) for about 5 minutes. Then, the pressure is rapidly released. In this process, the combined chemical and physical effects of lignin solubilization, hemicellulose hydrolysis, cellulose decrystallization, and increased surface

area enables near complete enzymatic conversion of cellulose and hemicellulose to fermentable sugars. AFEX pretreatment has the advantage that nearly all of the ammonia can be recovered and reused, while the remaining serves as nitrogen source for microbes in downstream processes. Also, a wash stream is not required for AFEX pretreatment. Thus, dry matter recovery following the AFEX treatment is essentially 100%. AFEX is basically a dry to dry process. The treated renewable carbon source is stable for long periods and can be fed at very high solid loadings in enzymatic hydrolysis or fermentation processes. Cellulose and hemicellulose are well preserved in the AFEX process, with little or no degradation. There is no need for neutralization prior to the enzymatic hydrolysis of a renewable carbon source that has undergone AFEX pretreatment. Enzymatic hydrolysis of AFEX-treated carbon sources produces clean sugar streams for subsequent fermentation use.

[0375] In some embodiments, the concentration of the carbon source (*e.g.*, a renewable carbon source) is equivalent to at least or about 0.1, 0.5, 1, 1.5, 2, 3, 4, 5, 10, 15, 20, 30, 40, or 50% glucose (w/v). The equivalent amount of glucose can be determined by using standard HPLC methods with glucose as a reference to measure the amount of glucose generated from the carbon source. In some embodiments, the concentration of the carbon source (*e.g.*, a renewable carbon source) is equivalent to between about 0.1 and about 20% glucose, such as between about 0.1 and about 10% glucose, between about 0.5 and about 10% glucose, between about 1 and about 10% glucose, between about 1 and about 5% glucose, or between about 1 and about 2% glucose.

[0376] In some embodiments, the carbon source includes yeast extract or one or more components of yeast extract. In some embodiments, the concentration of yeast extract is at least 1 gram of yeast extract per liter of broth (g/L, wherein the volume of broth includes both the volume of the cell medium and the volume of the cells), such as at least or about 5, 10, 15, 20, 30, 40, 50, 60, 80, 100, 150, 200, 300, or more g/L. In some embodiments, the concentration of yeast extract is between about 1 and about 300 g/L, such as between about 1 and about 200 g/L, between about 5 and about 200 g/L, between about 5 and about 100 g/L, or between about 5 and about 60 g/L. In some embodiments, the concentration includes the total amount of yeast extract that is added before and/or during the culturing of the host cells. In some embodiments, the carbon source includes both yeast extract (or one or more components thereof) and another carbon source, such as glucose. In some

embodiments, the ratio of yeast extract to the other carbon source is about 1:5, about 1:10, or about 1:20 (w/w).

[0377] Additionally the carbon source may also be one-carbon substrates such as carbon dioxide, or methanol. Glycerol production from single carbon sources (*e.g.*, methanol, formaldehyde, or formate) has been reported in methylotrophic yeasts (Yamada *et al.*, *Agric. Biol. Chem.*, 53(2) 541-543, 1989, which is hereby incorporated by reference in its entirety, particularly with respect to carbon sources) and in bacteria (Hunter *et. al.*, *Biochemistry*, 24, 4148-4155, 1985, which is hereby incorporated by reference in its entirety, particularly with respect to carbon sources). These organisms can assimilate single carbon compounds, ranging in oxidation state from methane to formate, and produce glycerol. The pathway of carbon assimilation can be through ribulose monophosphate, through serine, or through xylulose-momophosphate (Gottschalk, Bacterial Metabolism, Second Edition, Springer-Verlag: New York, 1986, which is hereby incorporated by reference in its entirety, particularly with respect to carbon sources). The ribulose monophosphate pathway involves the condensation of formate with ribulose-5-phosphate to form a six carbon sugar that becomes fructose and eventually the three carbon product glyceraldehyde-3-phosphate. Likewise, the serine pathway assimilates the one-carbon compound into the glycolytic pathway via methylenetetrahydrofolate.

[0378] In addition to one and two carbon substrates, methylotrophic organisms are also known to utilize a number of other carbon containing compounds such as methylamine, glucosamine and a variety of amino acids for metabolic activity. For example, methylotrophic yeast are known to utilize the carbon from methylamine to form trehalose or glycerol (Bellion *et al.*, *Microb. Growth Cl Compd.*, [Int. Symp.], 7th ed., 415-32. Editors: Murrell *et al.*, Publisher: Intercept, Andover, UK, 1993, which is hereby incorporated by reference in its entirety, particularly with respect to carbon sources). Similarly, various species of *Candida* metabolize alanine or oleic acid (Sulter *et al.*, *Arch. Microbiol.* 153(5), 485-9, 1990, which is hereby incorporated by reference in its entirety, particularly with respect to carbon sources).

[0379] In some embodiments, cells are cultured in a standard medium containing physiological salts and nutrients (*see, e.g.*, Pourquie, J. *et al.*, *Biochemistry and Genetics of Cellulose Degradation*, eds. Aubert *et al.*, Academic Press, pp. 71-86, 1988 and Ilmen *et al.*, *Appl. Environ. Microbiol.* 63:1298-1306, 1997, which are each hereby incorporated by

reference in their entireties, particularly with respect to cell medias). Exemplary growth media are common commercially prepared media such as Luria Bertani (LB) broth, Sabouraud Dextrose (SD) broth, or Yeast medium (YM) broth. Other defined or synthetic growth media may also be used, and the appropriate medium for growth of particular host cells are known by someone skilled in the art of microbiology or fermentation science.

[0380] In addition to an appropriate carbon source, the cell medium desirably contains suitable minerals, salts, cofactors, buffers, and other components known to those skilled in the art suitable for the growth of the cultures or the enhancement of isoprene production (*see*, for example, WO 2004/033646 and references cited therein and WO 96/35796 and references cited therein, which are each hereby incorporated by reference in their entireties, particularly with respect cell medias and cell culture conditions). In some embodiments where an isoprene synthase, DXS, IDI, and/or MVA pathway nucleic acid is under the control of an inducible promoter, the inducing agent (*e.g.*, a sugar, metal salt or antimicrobial), is desirably added to the medium at a concentration effective to induce expression of an isoprene synthase, DXS, IDI, and/or MVA pathway polypeptide. In some embodiments, cell medium has an antibiotic (such as kanamycin) that corresponds to the antibiotic resistance nucleic acid (such as a kanamycin resistance nucleic acid) on a vector that has one or more DXS, IDI, or MVA pathway nucleic acids.

Exemplary Cell Culture Conditions

[0381] Materials and methods suitable for the maintenance and growth of bacterial cultures are well known in the art. Exemplary techniques may be found in Manual of Methods for General Bacteriology Gerhardt *et al.*, eds), American Society for Microbiology, Washington, D.C. (1994) or Brock in Biotechnology: A Textbook of Industrial Microbiology, Second Edition (1989) Sinauer Associates, Inc., Sunderland, MA, which are each hereby incorporated by reference in their entireties, particularly with respect to cell culture techniques. In some embodiments, the cells are cultured in a culture medium under conditions permitting the expression of one or more isoprene synthase, DXS, IDI, or MVA pathway polypeptides encoded by a nucleic acid inserted into the host cells.

[0382] Standard cell culture conditions can be used to culture the cells (*see*, for example, WO 2004/033646 and references cited therein, which are each hereby incorporated by reference in their entireties, particularly with respect to cell culture and fermentation

conditions). Cells are grown and maintained at an appropriate temperature, gas mixture, and pH (such as at about 20 to about 37°C, at about 6% to about 84% CO₂, and at a pH between about 5 to about 9). In some embodiments, cells are grown at 35 °C in an appropriate cell medium. In some embodiments, *e.g.*, cultures are cultured at approximately 28 °C in appropriate medium in shake cultures or fermentors until desired amount of isoprene production is achieved. In some embodiments, the pH ranges for fermentation are between about pH 5.0 to about pH 9.0 (such as about pH 6.0 to about pH 8.0 or about 6.5 to about 7.0). Reactions may be performed under aerobic, anoxic, or anaerobic conditions based on the requirements of the host cells. Exemplary culture conditions for a given filamentous fungus are known in the art and may be found in the scientific literature and/or from the source of the fungi such as the American Type Culture Collection and Fungal Genetics Stock Center.

[0383] In various embodiments, the cells are grown using any known mode of fermentation, such as batch, fed-batch, or continuous processes. In some embodiments, a batch method of fermentation is used. Classical batch fermentation is a closed system where the composition of the media is set at the beginning of the fermentation and is not subject to artificial alterations during the fermentation. Thus, at the beginning of the fermentation the cell medium is inoculated with the desired host cells and fermentation is permitted to occur adding nothing to the system. Typically, however, “batch” fermentation is batch with respect to the addition of carbon source and attempts are often made at controlling factors such as pH and oxygen concentration. In batch systems, the metabolite and biomass compositions of the system change constantly until the time the fermentation is stopped. Within batch cultures, cells moderate through a static lag phase to a high growth log phase and finally to a stationary phase where growth rate is diminished or halted. In some embodiments, cells in log phase are responsible for the bulk of the isoprene production. In some embodiments, cells in stationary phase produce isoprene. In some embodiments, cells in log phase are responsible for the bulk of the ethylene production. In some embodiments, cells in stationary phase produce ethylene.

[0384] In some embodiments, a variation on the standard batch system is used, such as the Fed-Batch system. Fed-Batch fermentation processes comprise a typical batch system with the exception that the carbon source is added in increments as the fermentation progresses. Fed-Batch systems are useful when catabolite repression is apt to inhibit the metabolism of

the cells and where it is desirable to have limited amounts of carbon source in the cell medium. Fed-batch fermentations may be performed with the carbon source (*e.g.*, glucose) in a limited or excess amount. Measurement of the actual carbon source concentration in Fed-Batch systems is difficult and is therefore estimated on the basis of the changes of measurable factors such as pH, dissolved oxygen, and the partial pressure of waste gases such as CO₂. Batch and Fed-Batch fermentations are common and well known in the art and examples may be found in Brock, *Biotechnology: A Textbook of Industrial Microbiology*, Second Edition (1989) Sinauer Associates, Inc., which is hereby incorporated by reference in its entirety, particularly with respect to cell culture and fermentation conditions.

[0385] In some embodiments, continuous fermentation methods are used. Continuous fermentation is an open system where a defined fermentation medium is added continuously to a bioreactor and an equal amount of conditioned medium is removed simultaneously for processing. Continuous fermentation generally maintains the cultures at a constant high density where cells are primarily in log phase growth.

[0386] Continuous fermentation allows for the modulation of one factor or any number of factors that affect cell growth or isoprene production. For example, one method maintains a limiting nutrient such as the carbon source or nitrogen level at a fixed rate and allows all other parameters to moderate. In other systems, a number of factors affecting growth can be altered continuously while the cell concentration (*e.g.*, the concentration measured by media turbidity) is kept constant. Continuous systems strive to maintain steady state growth conditions. Thus, the cell loss due to media being drawn off is balanced against the cell growth rate in the fermentation. Methods of modulating nutrients and growth factors for continuous fermentation processes as well as techniques for maximizing the rate of product formation are well known in the art of industrial microbiology and a variety of methods are detailed by Brock, *Biotechnology: A Textbook of Industrial Microbiology*, Second Edition (1989) Sinauer Associates, Inc., which is hereby incorporated by reference in its entirety, particularly with respect to cell culture and fermentation conditions.

[0387] In some embodiments, cells are immobilized on a substrate as whole cell catalysts and subjected to fermentation conditions for isoprene or ethylene production.

[0388] In some embodiments, bottles of liquid culture are placed in shakers in order to introduce oxygen to the liquid and maintain the uniformity of the culture. In some embodiments, an incubator is used to control the temperature, humidity, shake speed, and/or other conditions in which a culture is grown. The simplest incubators are insulated boxes with an adjustable heater, typically going up to ~65 °C. More elaborate incubators can also include the ability to lower the temperature (via refrigeration), or the ability to control humidity or CO₂ levels. Most incubators include a timer; some can also be programmed to cycle through different temperatures, humidity levels, *etc.* Incubators can vary in size from tabletop to units the size of small rooms.

[0389] If desired, a portion or all of the cell medium can be changed to replenish nutrients and/or avoid the build up of potentially harmful metabolic byproducts and dead cells. In the case of suspension cultures, cells can be separated from the media by centrifuging or filtering the suspension culture and then resuspending the cells in fresh media. In the case of adherent cultures, the media can be removed directly by aspiration and replaced. In some embodiments, the cell medium allows at least a portion of the cells to divide for at least or about 5, 10, 20, 40, 50, 60, 65, or more cell divisions in a continuous culture (such as a continuous culture without dilution).

[0390] In some embodiments, a constitutive or leaky promoter (such as a Trc promoter) is used and a compound (such as IPTG) is not added to induce expression of the isoprene synthase, *efe*, DXS, IDI, or MVA pathway nucleic acid(s) operably linked to the promoter. In some embodiments, a compound (such as IPTG) is added to induce expression of the isoprene synthase, *efe*, DXS, IDI, or MVA pathway nucleic acid(s) operably linked to the promoter.

Exemplary Methods for Decoupling Isoprene Production from Cell Growth

[0391] Desirably, carbon from the feedstock is converted to isoprene rather than to the growth and maintenance of the cells. In some embodiments, the cells are grown to a low to medium OD₆₀₀, then production of isoprene is started or increased. This strategy permits a large portion of the carbon to be converted to isoprene.

[0392] In some embodiments, cells reach an optical density such that they no longer divide or divide extremely slowly, but continue to make isoprene for several hours (such as about 2, 4, 6, 8, 10, 15, 20, 25, 30, or more hours). For example, Figs. 60A-67C illustrate that cells

may continue to produce a substantial amount of mevalonic acid or isoprene after the cells reach an optical density such that they no longer divide or divide extremely slowly. In some cases, the optical density at 550 nm decreases over time (such as a decrease in the optical density after the cells are no longer in an exponential growth phase due to cell lysis), and the cells continue to produce a substantial amount of mevalonic acid or isoprene. In some embodiments, the optical density at 550 nm of the cells increases by less than or about 50% (such as by less than or about 40, 30, 20, 10, 5, or 0%) over a certain time period (such as greater than or about 5, 10, 15, 20, 25, 30, 40, 50 or 60 hours), and the cells produce isoprene at greater than or about 1, 10, 25, 50, 100, 150, 200, 250, 300, 400, 500, 600, 700, 800, 900, 1,000, 1,250, 1,500, 1,750, 2,000, 2,500, 3,000, 4,000, 5,000, or more nmole of isoprene/gram of cells for the wet weight of the cells/hour (nmole/g_{wcm}/hr) during this time period. In some embodiments, the amount of isoprene is between about 2 to about 5,000 nmole/g_{wcm}/hr, such as between about 2 to about 100 nmole/g_{wcm}/hr, about 100 to about 500 nmole/g_{wcm}/hr, about 150 to about 500 nmole/g_{wcm}/hr, about 500 to about 1,000 nmole/g_{wcm}/hr, about 1,000 to about 2,000 nmole/g_{wcm}/hr, or about 2,000 to about 5,000 nmole/g_{wcm}/hr. In some embodiments, the amount of isoprene is between about 20 to about 5,000 nmole/g_{wcm}/hr, about 100 to about 5,000 nmole/g_{wcm}/hr, about 200 to about 2,000 nmole/g_{wcm}/hr, about 200 to about 1,000 nmole/g_{wcm}/hr, about 300 to about 1,000 nmole/g_{wcm}/hr, or about 400 to about 1,000 nmole/g_{wcm}/hr.

[0393] In some embodiments, the optical density at 550 nm of the cells increases by less than or about 50% (such as by less than or about 40, 30, 20, 10, 5, or 0%) over a certain time period (such as greater than or about 5, 10, 15, 20, 25, 30, 40, 50 or 60 hours), and the cells produce a cumulative titer (total amount) of isoprene at greater than or about 1, 10, 25, 50, 100, 150, 200, 250, 300, 400, 500, 600, 700, 800, 900, 1,000, 1,250, 1,500, 1,750, 2,000, 2,500, 3,000, 4,000, 5,000, 10,000, 50,000, 100,000, or more mg of isoprene/L of broth (mg/L_{broth}, wherein the volume of broth includes the volume of the cells and the cell medium) during this time period. In some embodiments, the amount of isoprene is between about 2 to about 5,000 mg/L_{broth}, such as between about 2 to about 100 mg/L_{broth}, about 100 to about 500 mg/L_{broth}, about 500 to about 1,000 mg/L_{broth}, about 1,000 to about 2,000 mg/L_{broth}, or about 2,000 to about 5,000 mg/L_{broth}. In some embodiments, the amount of isoprene is between about 20 to about 5,000 mg/L_{broth}, about 100 to about 5,000 mg/L_{broth}, about 200 to about 2,000 mg/L_{broth}, about 200 to about 1,000 mg/L_{broth}, about 300 to about 1,000 mg/L_{broth}, or about 400 to about 1,000 mg/L_{broth}.

[0394] In some embodiments, the optical density at 550 nm of the cells increases by less than or about 50% (such as by less than or about 40, 30, 20, 10, 5, or 0%) over a certain time period (such as greater than or about 5, 10, 15, 20, 25, 30, 40, 50 or 60 hours), and the cells convert greater than or about 0.0015, 0.002, 0.005, 0.01, 0.02, 0.05, 0.1, 0.12, 0.14, 0.16, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0, 1.2, 1.4, 1.6, 1.8, 2.0, 2.5, 3.0, 3.5, 4.0, 5.0, 6.0, 7.0, or 8.0% of the carbon in the cell culture medium into isoprene during this time period. In some embodiments, the percent conversion of carbon into isoprene is between such as about 0.002 to about 4.0%, about 0.002 to about 3.0%, about 0.002 to about 2.0%, about 0.002 to about 1.6%, about 0.002 to about 0.005%, about 0.005 to about 0.01%, about 0.01 to about 0.05%, about 0.05 to about 0.15%, 0.15 to about 0.2%, about 0.2 to about 0.3%, about 0.3 to about 0.5%, about 0.5 to about 0.8%, about 0.8 to about 1.0%, or about 1.0 to about 1.6%. In some embodiments, the percent conversion of carbon into isoprene is between about 0.002 to about 0.4%, 0.002 to about 0.16%, 0.04 to about 0.16%, about 0.005 to about 0.3%, about 0.01 to about 0.3%, or about 0.05 to about 0.3%.

[0395] In some embodiments, isoprene is only produced in stationary phase. In some embodiments, isoprene is produced in both the growth phase and stationary phase. In various embodiments, the amount of isoprene produced (such as the total amount of isoprene produced or the amount of isoprene produced per liter of broth per hour per OD₆₀₀) during stationary phase is greater than or about 2, 3, 4, 5, 10, 20, 30, 40, 50, or more times the amount of isoprene produced during the growth phase for the same length of time. In various embodiments, greater than or about 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 95, 99% or more of the total amount of isoprene that is produced (such as the production of isoprene during a fermentation for a certain amount of time, such as 20 hours) is produced while the cells are in stationary phase. In various embodiments, greater than or about 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 95, 99% or more of the total amount of isoprene that is produced (such as the production of isoprene during a fermentation for a certain amount of time, such as 20 hours) is produced while the cells divide slowly or not at all such that the optical density at 550 nm of the cells increases by less than or about 50% (such as by less than or about 40, 30, 20, 10, 5, or 0%). In some embodiments, isoprene is only produced in the growth phase.

[0396] In some embodiments, one or more MVA pathway, IDI, DXP, or isoprene synthase nucleic acids are placed under the control of a promoter or factor that is more active in

stationary phase than in the growth phase. For example, one or more MVA pathway, IDI, DXP, or isoprene synthase nucleic acids may be placed under control of a stationary phase sigma factor, such as RpoS. In some embodiments, one or more MVA pathway, IDI, DXP, or isoprene synthase nucleic acids are placed under control of a promoter inducible in stationary phase, such as a promoter inducible by a response regulator active in stationary phase.

[0397] *Production of Isoprene within Safe Operating Ranges*

[0398] The production of isoprene within safe operating levels according to its flammability characteristics simplifies the design and construction of commercial facilities, vastly improves the ability to operate safely, and limits the potential for fires to occur. In particular, the optimal ranges for the production of isoprene are within the safe zone, *i.e.*, the nonflammable range of isoprene concentrations. In one such aspect, the invention features a method for the production of isoprene within the nonflammable range of isoprene concentrations (outside the flammability envelope of isoprene).

[0399] Thus, computer modeling and experimental testing were used to determine the flammability limits of isoprene (such as isoprene in the presence of O₂, N₂, CO₂, or any combination of two or more of the foregoing gases) in order to ensure process safety. The flammability envelope is characterized by the lower flammability limit (LFL), the upper flammability limit (UFL), the limiting oxygen concentration (LOC), and the limiting temperature. For a system to be flammable, a minimum amount of fuel (such as isoprene) must be in the presence of a minimum amount of oxidant, typically oxygen. The LFL is the minimum amount of isoprene that must be present to sustain burning, while the UFL is the maximum amount of isoprene that can be present. Above this limit, the mixture is fuel rich and the fraction of oxygen is too low to have a flammable mixture. The LOC indicates the minimum fraction of oxygen that must also be present to have a flammable mixture. The limiting temperature is based on the flash point of isoprene and is that lowest temperature at which combustion of isoprene can propagate. These limits are specific to the concentration of isoprene, type and concentration of oxidant, inerts present in the system, temperature, and pressure of the system. Compositions that fall within the limits of the flammability envelope propagate combustion and require additional safety precautions in both the design and operation of process equipment.

[0400] The following conditions were tested using computer simulation and mathematical analysis and experimental testing. If desired, other conditions (such as other temperature, pressure, and permanent gas compositions) may be tested using the methods described herein to determine the LFL, UFL, and LOC concentrations.

(1) Computer simulation and mathematical analysis

Test Suite 1:

isoprene: 0 wt% - 14 wt%

O₂: 6 wt% - 21 wt%

N₂: 79 wt% - 94 wt%

Test Suite 2:

isoprene: 0 wt% - 14 wt%

O₂: 6 wt% - 21 wt%

N₂: 79 wt% - 94 wt%

Saturated with H₂O

Test Suite 3:

isoprene: 0 wt% - 14 wt%

O₂: 6 wt% - 21 wt%

N₂: 79 wt% - 94 wt%

CO₂: 5 wt% - 30 wt%

(2) Experimental testing for final determination of flammability limits

Test Suite 1:

isoprene: 0 wt% - 14 wt%

O₂: 6 wt% - 21 wt%

N₂: 79 wt% - 94 wt%

Test Suite 2:

isoprene: 0 wt% - 14 wt%

O₂: 6 wt% - 21 wt%

N₂: 79 wt% - 94 wt%

Saturated with H₂O

[0401] Simulation software was used to give an estimate of the flammability characteristics of the system for several different testing conditions. CO₂ showed no significant affect on the system's flammability limits. Test suites 1 and 2 were confirmed by experimental testing. The modeling results were in-line with the experimental test results. Only slight variations were found with the addition of water.

[0402] The LOC was determined to be 9.5 vol% for an isoprene, O₂, N₂, and CO₂ mixture at 40°C and 1 atmosphere. The addition of up to 30% CO₂ did not significantly affect the flammability characteristics of an isoprene, O₂, and N₂ mixture. Only slight variations in flammability characteristics were shown between a dry and water saturated isoprene, O₂, and N₂ system. The limiting temperature is about -54 °C. Temperatures below about -54 °C are too low to propagate combustion of isoprene.

[0403] In some embodiments, the LFL of isoprene ranges from about 1.5 vol.% to about 2.0 vol%, and the UFL of isoprene ranges from about 2.0 vol.% to about 12.0 vol.%, depending on the amount of oxygen in the system. In some embodiments, the LOC is about 9.5 vol% oxygen. In some embodiments, the LFL of isoprene is between about 1.5 vol.% to about 2.0 vol%, the UFL of isoprene is between about 2.0 vol.% to about 12.0 vol.%, and the LOC is about 9.5 vol% oxygen when the temperature is between about 25 °C to about 55 °C (such as about 40 °C) and the pressure is between about 1 atmosphere and 3 atmospheres.

[0404] In some embodiments, isoprene is produced in the presence of less than about 9.5 vol% oxygen (that is, below the LOC required to have a flammable mixture of isoprene). In some embodiments in which isoprene is produced in the presence of greater than or about 9.5 vol% oxygen, the isoprene concentration is below the LFL (such as below about 1.5 vol.%). For example, the amount of isoprene can be kept below the LFL by diluting the isoprene composition with an inert gas (*e.g.*, by continuously or periodically adding an inert gas such as nitrogen to keep the isoprene composition below the LFL). In some embodiments in which isoprene is produced in the presence of greater than or about 9.5 vol% oxygen, the isoprene concentration is above the UFL (such as above about 12 vol.%). For example, the amount of isoprene can be kept above the UFL by using a system

(such as any of the cell culture systems described herein) that produces isoprene at a concentration above the UFL. If desired, a relatively low level of oxygen can be used so that the UFL is also relatively low. In this case, a lower isoprene concentration is needed to remain above the UFL.

[0405] In some embodiments in which isoprene is produced in the presence of greater than or about 9.5 vol% oxygen, the isoprene concentration is within the flammability envelope (such as between the LFL and the UFL). In some embodiments when the isoprene concentration may fall within the flammability envelope, one or more steps are performed to reduce the probability of a fire or explosion. For example, one or more sources of ignition (such as any materials that may generate a spark) can be avoided. In some embodiments, one or more steps are performed to reduce the amount of time that the concentration of isoprene remains within the flammability envelope. In some embodiments, a sensor is used to detect when the concentration of isoprene is close to or within the flammability envelope. If desired, the concentration of isoprene can be measured at one or more time points during the culturing of cells, and the cell culture conditions and/or the amount of inert gas can be adjusted using standard methods if the concentration of isoprene is close to or within the flammability envelope. In particular embodiments, the cell culture conditions (such as fermentation conditions) are adjusted to either decrease the concentration of isoprene below the LFL or increase the concentration of isoprene above the UFL. In some embodiments, the amount of isoprene is kept below the LFL by diluting the isoprene composition with an inert gas (such as by continuously or periodically adding an inert gas to keep the isoprene composition below the LFL).

[0406] In some embodiments, the amount of flammable volatiles other than isoprene (such as one or more sugars) is at least about 2, 5, 10, 50, 75, or 100-fold less than the amount of isoprene produced. In some embodiments, the portion of the gas phase other than isoprene gas comprises between about 0% to about 100% (volume) oxygen, such as between about 0% to about 10%, about 10% to about 20%, about 20% to about 30%, about 30% to about 40%, about 40% to about 50%, about 50% to about 60%, about 60% to about 70%, about 70% to about 80%, about 90% to about 90%, or about 90% to about 100% (volume) oxygen. In some embodiments, the portion of the gas phase other than isoprene gas comprises between about 0% to about 99% (volume) nitrogen, such as between about 0% to about 10%, about 10% to about 20%, about 20% to about 30%, about 30% to about

40%, about 40% to about 50%, about 50% to about 60%, about 60% to about 70%, about 70% to about 80%, about 90% to about 90%, or about 90% to about 99% (volume) nitrogen.

[0407] In some embodiments, the portion of the gas phase other than isoprene gas comprises between about 1% to about 50% (volume) CO₂, such as between about 1% to about 10%, about 10% to about 20%, about 20% to about 30%, about 30% to about 40%, or about 40% to about 50% (volume) CO₂.

[0408] In some embodiments, an isoprene composition also contains ethanol. For example, ethanol may be used for extractive distillation of isoprene, resulting in compositions (such as intermediate product streams) that include both ethanol and isoprene. Desirably, the amount of ethanol is outside the flammability envelope for ethanol. The LOC of ethanol is about 8.7 vol%, and the LFL for ethanol is about 3.3 vol% at standard conditions, such as about 1 atmosphere and about 60 °F (NFPA 69 *Standard on Explosion Prevention Systems*, 2008 edition, which is hereby incorporated by reference in its entirety, particularly with respect to LOC, LFL, and UFL values). In some embodiments, compositions that include isoprene and ethanol are produced in the presence of less than the LOC required to have a flammable mixture of ethanol (such as less than about 8.7% vol%). In some embodiments in which compositions that include isoprene and ethanol are produced in the presence of greater than or about the LOC required to have a flammable mixture of ethanol, the ethanol concentration is below the LFL (such as less than about 3.3 vol.%).

[0409] In various embodiments, the amount of oxidant (such as oxygen) is below the LOC of any fuel in the system (such as isoprene or ethanol). In various embodiments, the amount of oxidant (such as oxygen) is less than about 60, 40, 30, 20, 10, or 5% of the LOC of isoprene or ethanol. In various embodiments, the amount of oxidant (such as oxygen) is less than the LOC of isoprene or ethanol by at least 2, 4, 5, or more absolute percentage points (vol %). In particular embodiments, the amount of oxygen is at least 2 absolute percentage points (vol %) less than the LOC of isoprene or ethanol (such as an oxygen concentration of less than 7.5 vol% when the LOC of isoprene is 9.5 vol%). In various embodiments, the amount of fuel (such as isoprene or ethanol) is less than or about 25, 20, 15, 10, or 5% of the LFL for that fuel.

[0410] High Efficiency Production and Recovery of Isoprene, a volatile hydrocarbon, by Fermentation

[0411] Further, provided herein are methods for the high efficiency production and recovery of volatiles such as isoprene using reduced gas-sparging rates. The use of reduced gas-sparging rates facilitates the recovery of isoprene and other volatiles (such as ethylene) by increasing the concentration of the volatile in the fermentation off-gas, which can facilitate downstream recovery of the volatile from permanent gases and other impurities. Another advantage of volatile production and recovery at reduced gas-sparging rates is that the amount of oxygen present in the off-gas is reduced as a greater percentage of the initial oxygen is consumed by the cells in the fermentor. Low oxygen concentrations are advantageous as the reaction of oxygen with isoprene to form undesirable polymers and oxidized compounds is reduced. In addition, the use of reduced gas-sparging rates maximizes the amount of volatile in the off-gas, while minimizing permanent gases, in particular oxygen. The maximization of the amount of the volatile is also important in maintaining safe operating conditions in view of the extremely volatile nature of isoprene and other unsaturated hydrocarbons in the process as discussed above.

[0412] The continuous removal of volatile organic compounds (VOCs) from fermentation broth by gas stripping is most effective for substances whose physical properties favor partitioning into the gas phase at ambient temperatures and pressures. In general, a compound can be recovered by gas stripping if it possesses a high vapor pressure at fermentation temperatures, combined with low water solubility. The Henry's law coefficient is also used to estimate the effectiveness of gas stripping for removal of organic compounds from aqueous solution. At equilibrium, the relation between the concentrations of a volatile compound in the liquid and gaseous phases is given by Henry's gas law (eq. 1).

$$P = kC \quad (\text{eq. 1})$$

[0413] Where P is the partial pressure, C the aqueous concentration and k is Henry's law coefficient. Under dynamic conditions, such as the case of a gas-sparged fermentator producing a volatile organic compound, the concentration of a volatile in the liquid phase is dependant on several additional factors, summarized below;

- i) Rate of volatile production (g/L/hr)
- ii) Gas sparging rate (vvm)
- iii) Bubble surface area (m⁻²)
- iv) Agitation rate

[0414] Thus at a constant rate of volatile production, higher gas-sparging rates will tend to reduce the steady-state aqueous concentration of the volatile. The rate of volatile mass transfer from the liquid to the gaseous phase (or *vice versa*) is a function of the difference between the aqueous volatile concentration and the expected concentration at equilibrium, multiplied by a mass transfer coefficient.

$$F = K_L [C - (P/k)] \quad (\text{eq. 2})$$

[0415] Where F is flux (mol s⁻¹), K_L the gas transfer velocity (m s⁻¹), C the aqueous volatile concentration, P is partial pressure and k representing Henry's gas law coefficient for the volatile. When the aqueous concentration is greater than the equilibrium concentration, gas efflux will occur from the liquid to the gaseous phase. The gas transfer velocity, K_L , will also be influenced by the total gas/liquid surface area, which will change as a function of the degree of agitation of the fermentation broth. For a well stirred fermentor, it can be assumed that the bulk gas and liquid phases are at equilibrium, and thus the aqueous concentration of a volatile is predominantly a function of the partial pressure in the gas phase above the liquid, in accordance with Henry's law (eq. 1). It should be understood that the value of Henry's coefficient varies with temperature and the composition of the aqueous phase of the system. Thus, the actual amount of isoprene present in aqueous fermentation broth at a give time may vary from the theoretical amount in an ideal system.

[0416] For isoprene at 298K, the Henry's Law coefficient is 0.029 M/atm. *See* Weitz and Loser in *Ullmann's Encyclopedia of Industrial Chemistry*, 7th edn., Electronic release, Wiley-VCH Verlag GMBH, Weinheim (2005); *see also* Karl *et al.* (2003) *Int. J. Mass Spec.*, 223–224, 383–395, which are incorporated by reference in their entirety, particularly with respect to Henry's Law coefficient calculations. Therefore, if the off-gas exiting the fermentor has an isoprene partial pressure of 0.01 atm (1% v/v) at 0.5 vvm, then the steady state liquid concentration in the fermentation broth will be 0.29 mM, or about 20 mg/L. Doubling the airflow to 1 vvm will halve the partial pressure of isoprene above the fermentor to 0.05%, and therefore the liquid phase concentration will be reduced to around 10 mg/L.

[0417] Methods are provided herein of producing isoprene comprising a) culturing cells under suitable conditions for production of isoprene; and b) producing isoprene, wherein the liquid phase concentration of isoprene is less than about 2 g/L. In some embodiments, the liquid phase concentration of isoprene in the culture is less than about 1 g/L. In some embodiments, the liquid phase concentration of isoprene in the culture is less than about 200 mg/L. In some embodiments, the liquid phase concentration of isoprene in the culture is less than any of about 1.9 g/L, 1.8 g/L, 1.7 g/L, 1.6 g/L, 1.5 g/L, 1.4 g/L, 1.3 g/L, 1.2 g/L, or 1.1 g/L. In some embodiments, the liquid phase concentration of isoprene in the culture is less than any of about 900 mg/L, 800 mg/L, 700 mg/L, 600 mg/L, 500 mg/L, 400 mg/L, or 300 mg/L. In some embodiments, the liquid phase concentration of isoprene in the culture is less than about any of 175 mg/L, 150 mg/L, 125 mg/L, 100 mg/L, 75 mg/L, 50 mg/L, 25 mg/L, 20 mg/L, 15 mg/L, 10 mg/L, 5 mg/L, or 2.5 mg/L. In some embodiments, the liquid phase concentration of isoprene in culture is between about any of 0.1 mg/L to 200 mg/L, 1 mg/L to 200 mg/L, 1 mg/L to 150 mg/L, 1 mg/L to 100 mg/L, 1 mg/L to 50 mg/L, 1 mg/L to 25 mg/L, 1 mg/L to 20 mg/L, or 10 mg/L to 20 mg/L, 1 mg/L to 1 g/L, 0.1 mg/L to 2 g/L, 1 g/L to 2 g/L, 10 mg/L to 1 g/L, or 100 mg/L to 1 g/L. In some embodiments, the isoprene produced is any concentration or amount disclosed in the section entitled "Exemplary Production of Isoprene." In some embodiments, the liquid phase concentration is below the solubility limit of isoprene. In some embodiments, the liquid phase in the culture is saturated with isoprene, and isoprene is additionally present in a second liquid phase. In some embodiments, the second liquid phase comprises at least about 50, 60, 70, 80, 85, 90, 95, or 98% isoprene.

[0418] In some embodiments of the methods, the cells produce greater than about 400 nmole/g_{wcm}/hour of isoprene. In some embodiments, the amount of isoprene is between about any of 400 nmole/g_{wcm}/hour to 1 mole/g_{wcm}/hour, 400 nmole/g_{wcm}/hour to 1 mmole/g_{wcm}/hour, 400 nmole/g_{wcm}/hour to 40 mmole/g_{wcm}/hour, 400 nmole/g_{wcm}/hour to 4 mmole/g_{wcm}/hour, 1 mmole/g_{wcm}/hour to 1.5 mmole/g_{wcm}/hour, 1.5 mmole/g_{wcm}/hour to 3 mmole/g_{wcm}/hour, 3 mmole/g_{wcm}/hour to 5 mmole/g_{wcm}/hour, 5 mmole/g_{wcm}/hour to 25 mmole/g_{wcm}/hour, 25 mmole/g_{wcm}/hour to 100 mmole/g_{wcm}/hour, 100 mmole/g_{wcm}/hour to 500 mmole/g_{wcm}/hour, or 500 mmole/g_{wcm}/hour to 1000 mmole/g_{wcm}/hour. In some embodiments, the amount of isoprene is about any of 1 mmole/g_{wcm}/hour, 1.5 mmole/g_{wcm}/hour, 2 mmole/g_{wcm}/hour, 3 mmole/g_{wcm}/hour, 4 mmole/g_{wcm}/hour, or 5 mmole/g_{wcm}/hour.

[0419] The low value for Henry's coefficient means that isoprene can be recovered from fermentation broth by gas stripping at low sparging rates, for example 0.01 vvm to 2 vvm. In some embodiments, the gas sparging rate is between about any of 0 vvm to 0.01 vvm, 0.01 vvm to 0.1 vvm, 0.1 vvm to 1 vvm, 0.01 vvm to 0.5 vvm, 0.2 vvm to 1 vvm, or 0.5 vvm to 1 vvm. In some embodiments, the gas sparging rate is about any of 0.1 vvm, 0.25 vvm, 0.5 vvm, 0.75 vvm, 1 vvm, 1.25 vvm, 1.5 vvm, 1.75 vvm, or 2 vvm. In one embodiment, gas sparging is not used. In some embodiments, the low sparging rates are maintained for the entire course of the fermentation run, during growth phase, or during stationary phase. In some embodiments, the low sparging rates are maintained for between about any of 1 hour to 5 hours, 5 hours to 10 hours, 10 hours to 20 hours, 20 hours to 30 hours, 30 hours to 40 hours, 40 hours to 50 hours, or 50 hours to 60 hours. The lower desirable gas sparge limit is defined by the point at which the aqueous phase becomes saturated with isoprene and a liquid organic phase forms. This can only occur below the boiling point of isoprene (34.1°C at 1 atm), above which a liquid isoprene phase will never form. At temperatures below the boiling point of isoprene, the formation of a liquid phase is determined by the aqueous solubility of isoprene, which is approximately 650 mg/L at 25°C. While it is highly desirable to avoid the formation of a liquid isoprene phase, it is not absolutely required provided that the cells can tolerate the presence of liquid isoprene without toxic effects.

[0420] In some embodiments, the oxygen, CO₂, and isoprene are any of the amounts or concentrations discussed in the section entitled "Production of Isoprene with Safe Operating Ranges." In some embodiments, all the oxygen is consumed by the cells while maintaining fully aerobic metabolism. In some embodiments, an excess of oxygen is used in order to satisfy the oxygen demands of the cells. Desirable ranges of oxygen in the off-gas are less than 20%, or less than 15% or less than 10% (v/v). Levels of oxygen below the limiting oxygen concentration required for combustion of isoprene (9.5% v/v at 1 atm) are particularly desirable. In some embodiments, oxygen-enriched air is utilized with the purpose of allowing minimal gas sweep rates while satisfying the cellular oxygen demand. In some embodiments, the portion of the gas phase of the gas sweep comprises between about 0.1% to about 10%, about 10% to about 20%, or about 20% to about 30% (volume) oxygen. In some embodiments, isoprene fermentations are performed under high pressure in order minimize the amount of excess oxygen required to maintain the required dissolved oxygen levels in the liquid phase.

[0421] In some embodiments, the reduction of the gas sweep rate through the fermentor is advantageous for an integrated isoprene production process in that such conditions enrich the off-gas isoprene levels up to about 30,000 ug/L (about 1% v/v) without adversely affecting the physiology of the cells.

[0422] In some embodiments, reduced gas-sparge rates do not significantly adversely affect the physiology of the cells. In some embodiments, the carbon dioxide evolution rate of cells in culture with reduced gas-sparge rates is between about any of 1×10^{-18} mmol/L/hour to about 1 mol/L/hour, 1 mmol/L/hour to 1 mol/L/hour, 25 mmol/L/hour to 750 mmol/L/hour, 25 mmol/L/hour to 75 mmol/L/hour, 250 mmol/L/hour to 750 mmol/L/hour, or 450 mmol/L/hour to 550 mmol/L/hour. In some embodiments, the carbon dioxide evolution rate is about any of 50 mmol/L/hour, 100 mmol/L/hour, 150 mmol/L/hour, 200 mmol/L/hour, 250 mmol/L/hour, 300 mmol/L/hour, 350 mmol/L/hour, 400 mmol/L/hour, 450 mmol/L/hour, or 500 mmol/L/hour. In some embodiments, cell viability with reduced gas-sparge rates is reduced by less than about any of 1.75-fold, 1.5-fold, 1.25-fold, 1-fold, 0.75-fold, 0.5-fold, or 0.25-fold. In some embodiments, cell viability with reduced gas-sparge rates is reduced by about 2-fold. In some embodiments, cell viability with reduced gas-sparge rates of a cell expressing a MVA pathway and/or DXP pathway RNA and/or protein from one or more of a heterologous and/or duplicate copy of a MVA pathway and/or DXP pathway nucleic acid is compared to a control cell lacking one or more of a heterologous and/or duplicate copy of a MVA pathway and/or DXP pathway nucleic acid with reduced gas-sparge rates. In some embodiments, cell viability with reduced gas-sparge rates of a cell expressing a MVA pathway and/or DXP pathway RNA and/or protein from one or more of a heterologous and/or duplicate copy of a MVA pathway and/or DXP pathway nucleic acid under the control of an inducible promoter, wherein the promoter is induced, is compared to a control cell containing one or more of a heterologous and/or duplicate copy of a MVA pathway and/or DXP pathway nucleic acid under the control of an inducible promoter, wherein the promoter is not induced (uninduced) with reduced gas-sparge rates. In some embodiments, the inducible promoter is a beta-galactosidase promoter.

[0423] In some embodiments, the fermentation of a genetically modified host organism that converts at least 5% of the total carbon consumed by the organism into a volatile, unsaturated hydrocarbon. In some embodiments, the production of an unsaturated

hydrocarbon at such a rate as to be present in the fermentation off-gas at a level of at least about any of 100 ug/L, 500 ug/L, 1000 ug/L, 2, 500 ug/L, 5,000 ug/L, 7,500 ug/L, or 10,000 ug/L.

[0424] In some embodiments, the unsaturated hydrocarbon is recovered from the off-gas stream in a manner that is suited to high-rates of production, which correspond to concentrations in the offgas of at least about any of 100 ug/L, 500 ug/L, 1000 ug/L, 2,500 ug/L, 5,000 ug/L, 7,500 ug/L, or 10,000 ug/L. In some embodiments, the continuous extraction and recovery of an unsaturated hydrocarbon from the fermentation off-gas in particular at low gas sweep rates such that the resulting off-gas is enriched in the volatile component of interest. In some embodiments, recovery of the volatile hydrocarbon by methods that depend on elevated concentrations of the volatile. For example, efficient capture of isoprene in fermentation off-gas through the use of compression/condensation or extractive distillation technologies. Also contemplated is the use of activated carbon cartridges in addition to silica gel adsorbants, desorption and concentration of isoprene from carbon cartridges, and/or construction and fermentation of host organisms such as *E. coli strains* that can convert about 5% or more of the glucose substrate to isoprene and result in off-gas concentrations of greater than about 15,000 ug/L isoprene. Recovery methods include any of the methods described herein.

[0425] Also provided herein are methods of producing a compound, wherein the compound has one or more characteristics selected from the group consisting of (a) a Henry's law coefficient of less than about 250 M/atm and (b) a solubility in water of less than about 100 g/L. In some embodiments, the method comprises: a) culturing cells under suitable conditions for production of the compound, wherein gas is added (such as the addition of gas to a system such as a fermentation system) at a gas sparging rate between about 0.01 vvm to about 2 vvm; and b) producing the compound. In one embodiment, the gas sparging rate is 0 vvm. In another embodiment, the gas sparging rate is 0 to 0.01 vvm.

[0426] In some embodiments, the amount of the compound that partitions into the cell mass is not included in the liquid phase solubility values. In some embodiments, the liquid phase concentration is below the solubility limit of compound.

[0427] In some embodiments, the compounds can be continuously recovered from fermentation broth by gas stripping at moderate to low gas sparging rates, in particular

those compounds with Henry's law coefficients of about any of less than 250 M/atm, 200 M/atm, 150 M/atm, 100 M/atm, 75 M/atm, 50 M/atm, 25 M/atm, 10 M/atm, 5 M/atm, or 1 M/atm. Examples include aldehydes such as acetaldehyde (15 M/atm), ketones such as acetone (30 M/atm), methyl ethyl ketone (100 M/atm), or 2-butanone (20 M/atm), or alcohols including methanol (220 M/atm), ethanol (200 M/atm), 1-butanol (120 m/atm) or C5 alcohols including 3-methyl-3-buten-1-ol, and 3-methyl-2-buten-1-ol (50- 100 M/atm). Esters of alcohols generally have lower Henry's constants than the respective alcohols, for example ethyl acetate (6-9 M/atm) or the acetyl esters of C5 alcohols (<5 M/atm). Compounds with Henry's law coefficients of less than 1M/atm are particularly desirable. Examples include hemiterpenes, monoterpenes, or sesquiterpenes, in addition to other hydrocarbons such as C1 to C5 hydrocarbons (*e.g.*, methane, ethane, ethylene, or propylene). In some embodiments, the hydrocarbons such as C1 to C5 hydrocarbons are saturated, unsaturated, or branched. In some embodiments, the C1 to C5 hydrocarbon is an unsaturated aliphatic hydrocarbon (*e.g.* ethylene, propylene, butylene, or isobutylene). In some embodiments, the C1 to C5 hydrocarbon is a diolefin.

[0428] In general, there is a correlation between Henry's law coefficient and water solubility in that compounds with very low coefficients are sparingly soluble in water (substantially water insoluble). Although volatiles with infinite solubilities in water (*e.g.* acetone or ethanol) can be removed by gas stripping, desirable solubility limits are less than about any of 100 g/L, 75 g/L, 50 g/L, 25 g/L, 10 g/L, 5 g/L, or 1g/L.

[0429] In some embodiments of any of the methods of producing any of the compounds described above, the gas sparging rate is between about any of 0 vvm to 0.01 vvm, 0.01 vvm to 0.1 vvm, 0.1 vvm to 1 vvm, 0.2 vvm to 1 vvm, or 0.5 vvm to 1 vvm. In some embodiments, the gas sparging rate is about any of 0.1 vvm, 0.25 vvm, 0.5 vvm, 0.75 vvm, 1 vvm, 1.25 vvm, 1.5 vvm, 1.75 vvm, or 2 vvm. In some embodiments, the low sparging rates are maintained for the entire course of the fermentation run, during growth phase, or during stationary phase. In some embodiments, the low sparging rates are maintained for between about any of 1 hour to 5 hours, 5 hours to 10 hours, 10 hours to 20 hours, 20 hours to 30 hours, 30 hours to 40 hours, 40 hours to 50 hours, or 50 hours to 60 hours.

[0430] Any of the systems described herein can be used in the methods of producing a compound described above. Standard method would be used to purify such as those

described in the section entitled “Exemplary Purification Methods.” Separate can be performed post-recovery for example, by distillation or selective adsorption techniques.

[0431] Exemplary Production of Isoprene

[0432] In some embodiments, the cells are cultured in a culture medium under conditions permitting the production of isoprene by the cells. By “peak absolute productivity” is meant the maximum absolute amount of isoprene in the off-gas during the culturing of cells for a particular period of time (*e.g.*, the culturing of cells during a particular fermentation run). By “peak absolute productivity time point” is meant the time point during a fermentation run when the absolute amount of isoprene in the off-gas is at a maximum during the culturing of cells for a particular period of time (*e.g.*, the culturing of cells during a particular fermentation run). In some embodiments, the isoprene amount is measured at the peak absolute productivity time point. In some embodiments, the peak absolute productivity for the cells is about any of the isoprene amounts disclosed herein.

[0433] By “peak specific productivity” is meant the maximum amount of isoprene produced per cell during the culturing of cells for a particular period of time (*e.g.*, the culturing of cells during a particular fermentation run). By “peak specific productivity time point” is meant the time point during the culturing of cells for a particular period of time (*e.g.*, the culturing of cells during a particular fermentation run) when the amount of isoprene produced per cell is at a maximum. The specific productivity is determined by dividing the total productivity by the amount of cells, as determined by optical density at 600nm (OD_{600}). In some embodiments, the isoprene amount is measured at the peak specific productivity time point. In some embodiments, the peak specific productivity for the cells is about any of the isoprene amounts per cell disclosed herein.

[0434] By “peak concentration” is meant the maximum amount of isoprene produced during the culturing of cells for a particular period of time (*e.g.*, the culturing of cells during a particular fermentation run). By “peak concentration time point” is meant the time point during the culturing of cells for a particular period of time (*e.g.*, the culturing of cells during a particular fermentation run) when the amount of isoprene produced per cell is at a maximum. In some embodiments, the isoprene amount is measured at the peak concentration time point. In some embodiments, the peak concentration for the cells is about any of the isoprene amounts disclosed herein.

[0435] By “cumulative total productivity” is meant the cumulative, total amount of isoprene produced during the culturing of cells for a particular period of time (*e.g.*, the culturing of cells during a particular fermentation run). In some embodiments, the cumulative, total amount of isoprene is measured. In some embodiments, the cumulative total productivity for the cells is about any of the isoprene amounts disclosed herein.

[0436] By “relative detector response” refers to the ratio between the detector response (such as the GC/MS area) for one compound (such as isoprene) to the detector response (such as the GC/MS area) of one or more compounds (such as all C5 hydrocarbons). The detector response may be measured as described herein, such as the GC/MS analysis performed with an Agilent 6890 GC/MS system fitted with an Agilent HP-5MS GC/MS column (30 m x 250 μ m; 0.25 μ m film thickness). If desired, the relative detector response can be converted to a weight percentage using the response factors for each of the compounds. This response factor is a measure of how much signal is generated for a given amount of a particular compound (that is, how sensitive the detector is to a particular compound). This response factor can be used as a correction factor to convert the relative detector response to a weight percentage when the detector has different sensitivities to the compounds being compared. Alternatively, the weight percentage can be approximated by assuming that the response factors are the same for the compounds being compared. Thus, the weight percentage can be assumed to be approximately the same as the relative detector response.

[0437] In some embodiments, the cells in culture produce isoprene at greater than or about 1, 10, 25, 50, 100, 150, 200, 250, 300, 400, 500, 600, 700, 800, 900, 1,000, 1,250, 1,500, 1,750, 2,000, 2,500, 3,000, 4,000, 5,000, or more nmole of isoprene/gram of cells for the wet weight of the cells/hour (nmole/g_{wcm}/hr). In some embodiments, the amount of isoprene is between about 2 to about 5,000 nmole/g_{wcm}/hr, such as between about 2 to about 100 nmole/g_{wcm}/hr, about 100 to about 500 nmole/g_{wcm}/hr, about 150 to about 500 nmole/g_{wcm}/hr, about 500 to about 1,000 nmole/g_{wcm}/hr, about 1,000 to about 2,000 nmole/g_{wcm}/hr, or about 2,000 to about 5,000 nmole/g_{wcm}/hr. In some embodiments, the amount of isoprene is between about 20 to about 5,000 nmole/g_{wcm}/hr, about 100 to about 5,000 nmole/g_{wcm}/hr, about 200 to about 2,000 nmole/g_{wcm}/hr, about 200 to about 1,000 nmole/g_{wcm}/hr, about 300 to about 1,000 nmole/g_{wcm}/hr, or about 400 to about 1,000 nmole/g_{wcm}/hr.

[0438] The amount of isoprene in units of nmole/g_{wcm}/hr can be measured as disclosed in U.S. Patent No. 5,849,970, which is hereby incorporated by reference in its entirety, particularly with respect to the measurement of isoprene production. For example, two mL of headspace (*e.g.*, headspace from a culture such as 2 mL of culture cultured in sealed vials at 32°C with shaking at 200 rpm for approximately 3 hours) are analyzed for isoprene using a standard gas chromatography system, such as a system operated isothermally (85°C) with an n-octane/porasil C column (Alltech Associates, Inc., Deerfield, Ill.) and coupled to a RGD2 mercuric oxide reduction gas detector (Trace Analytical, Menlo Park, CA) (*see*, for example, Greenberg et al, *Atmos. Environ.* 27A: 2689-2692, 1993; Silver *et al.*, *Plant Physiol.* 97:1588-1591, 1991, which are each hereby incorporated by reference in their entireties, particularly with respect to the measurement of isoprene production). The gas chromatography area units are converted to nmol isoprene via a standard isoprene concentration calibration curve. In some embodiments, the value for the grams of cells for the wet weight of the cells is calculated by obtaining the A₆₀₀ value for a sample of the cell culture, and then converting the A₆₀₀ value to grams of cells based on a calibration curve of wet weights for cell cultures with a known A₆₀₀ value. In some embodiments, the grams of the cells is estimated by assuming that one liter of broth (including cell medium and cells) with an A₆₀₀ value of 1 has a wet cell weight of 1 gram. The value is also divided by the number of hours the culture has been incubating for, such as three hours.

[0439] In some embodiments, the cells in culture produce isoprene at greater than or about 1, 10, 25, 50, 100, 150, 200, 250, 300, 400, 500, 600, 700, 800, 900, 1,000, 1,250, 1,500, 1,750, 2,000, 2,500, 3,000, 4,000, 5,000, 10,000, 100,000, or more ng of isoprene/gram of cells for the wet weight of the cells/hr (ng/g_{wcm}/h). In some embodiments, the amount of isoprene is between about 2 to about 5,000 ng/g_{wcm}/h, such as between about 2 to about 100 ng/g_{wcm}/h, about 100 to about 500 ng/g_{wcm}/h, about 500 to about 1,000 ng/g_{wcm}/h, about 1,000 to about 2,000 ng/g_{wcm}/h, or about 2,000 to about 5,000 ng/g_{wcm}/h. In some embodiments, the amount of isoprene is between about 20 to about 5,000 ng/g_{wcm}/h, about 100 to about 5,000 ng/g_{wcm}/h, about 200 to about 2,000 ng/g_{wcm}/h, about 200 to about 1,000 ng/g_{wcm}/h, about 300 to about 1,000 ng/g_{wcm}/h, or about 400 to about 1,000 ng/g_{wcm}/h. The amount of isoprene in ng/g_{wcm}/h can be calculated by multiplying the value for isoprene production in the units of nmole/g_{wcm}/hr discussed above by 68.1 (as described in Equation 5 below).

[0440] In some embodiments, the cells in culture produce a cumulative titer (total amount) of isoprene at greater than or about 1, 10, 25, 50, 100, 150, 200, 250, 300, 400, 500, 600, 700, 800, 900, 1,000, 1,250, 1,500, 1,750, 2,000, 2,500, 3,000, 4,000, 5,000, 10,000, 50,000, 100,000, or more mg of isoprene/L of broth (mg/L_{broth}, wherein the volume of broth includes the volume of the cells and the cell medium). In some embodiments, the amount of isoprene is between about 2 to about 5,000 mg/L_{broth}, such as between about 2 to about 100 mg/L_{broth}, about 100 to about 500 mg/L_{broth}, about 500 to about 1,000 mg/L_{broth}, about 1,000 to about 2,000 mg/L_{broth}, or about 2,000 to about 5,000 mg/L_{broth}. In some embodiments, the amount of isoprene is between about 20 to about 5,000 mg/L_{broth}, about 100 to about 5,000 mg/L_{broth}, about 200 to about 2,000 mg/L_{broth}, about 200 to about 1,000 mg/L_{broth}, about 300 to about 1,000 mg/L_{broth}, or about 400 to about 1,000 mg/L_{broth}.

[0441] The specific productivity of isoprene in mg of isoprene/L of headspace from shake flask or similar cultures can be measured by taking a 1 ml sample from the cell culture at an OD₆₀₀ value of approximately 1.0, putting it in a 20 mL vial, incubating for 30 minutes, and then measuring the amount of isoprene in the headspace (as described, for example, in Example I, part II). If the OD₆₀₀ value is not 1.0, then the measurement can be normalized to an OD₆₀₀ value of 1.0 by dividing by the OD₆₀₀ value. The value of mg isoprene/L headspace can be converted to mg/L_{broth}/hr/OD₆₀₀ of culture broth by multiplying by a factor of 38. The value in units of mg/L_{broth}/hr/OD₆₀₀ can be multiplied by the number of hours and the OD₆₀₀ value to obtain the cumulative titer in units of mg of isoprene/L of broth.

[0442] The instantaneous isoprene production rate in mg/L_{broth}/hr in a fermentor can be measured by taking a sample of the fermentor off-gas, analyzing it for the amount of isoprene (in units such as mg of isoprene per L_{gas}) as described, for example, in Example I, part II and multiplying this value by the rate at which off-gas is passed through each liter of broth (*e.g.*, at 1 vvm (volume of air/volume of broth/minute) this is 60 L_{gas} per hour). Thus, an off-gas level of 1 mg/L_{gas} corresponds to an instantaneous production rate of 60 mg/L_{broth}/hr at air flow of 1 vvm. If desired, the value in the units mg/L_{broth}/hr can be divided by the OD₆₀₀ value to obtain the specific rate in units of mg/L_{broth}/hr/OD. The average value of mg isoprene/L_{gas} can be converted to the total product productivity (grams of isoprene per liter of fermentation broth, mg/L_{broth}) by multiplying this average off-gas isoprene concentration by the total amount of off-gas sparged per liter of

fermentation broth during the fermentation. Thus, an average off-gas isoprene concentration of 0.5 mg/L_{broth}/hr over 10 hours at 1 vvm corresponds to a total product concentration of 300 mg isoprene/L_{broth}.

[0443] In some embodiments, the cells in culture convert greater than or about 0.0015, 0.002, 0.005, 0.01, 0.02, 0.05, 0.1, 0.12, 0.14, 0.16, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0, 1.2, 1.4, 1.6, 1.8, 2.0, 2.5, 3.0, 3.5, 4.0, 5.0, 6.0, 7.0, or 8.0% of the carbon in the cell culture medium into isoprene. In some embodiments, the percent conversion of carbon into isoprene is between such as about 0.002 to about 4.0%, about 0.002 to about 3.0%, about 0.002 to about 2.0%, about 0.002 to about 1.6%, about 0.002 to about 0.005%, about 0.005 to about 0.01%, about 0.01 to about 0.05%, about 0.05 to about 0.15%, 0.15 to about 0.2%, about 0.2 to about 0.3%, about 0.3 to about 0.5%, about 0.5 to about 0.8%, about 0.8 to about 1.0%, or about 1.0 to about 1.6%. In some embodiments, the percent conversion of carbon into isoprene is between about 0.002 to about 0.4%, 0.002 to about 0.16%, 0.04 to about 0.16%, about 0.005 to about 0.3%, about 0.01 to about 0.3%, or about 0.05 to about 0.3%.

[0444] The percent conversion of carbon into isoprene (also referred to as “% carbon yield”) can be measured by dividing the moles carbon in the isoprene produced by the moles carbon in the carbon source (such as the moles of carbon in batched and fed glucose and yeast extract). This number is multiplied by 100% to give a percentage value (as indicated in Equation 1).

Equation 1

$$\% \text{ Carbon Yield} = (\text{moles carbon in isoprene produced}) / (\text{moles carbon in carbon source}) * 100$$

[0445] For this calculation, yeast extract can be assumed to contain 50% w/w carbon. As an example, for the 500 liter described in Example 7, part VIII, the percent conversion of carbon into isoprene can be calculated as shown in Equation 2.

Equation 2

$$\% \text{ Carbon Yield} = (39.1 \text{ g isoprene} * 1/68.1 \text{ mol/g} * 5 \text{ C/mol}) / [(181221 \text{ g glucose} * 1/180 \text{ mol/g} * 6 \text{ C/mol}) + (17780 \text{ g yeast extract} * 0.5 * 1/12 \text{ mol/g})] * 100 = 0.042\%$$

[0446] For the two 500 liter fermentations described herein (Example 7, parts VII and VIII), the percent conversion of carbon into isoprene was between 0.04-0.06%. A 0.11-0.16% carbon yield has been achieved using 14 liter systems as described herein. Example 11, part V describes the 1.53% conversion of carbon to isoprene using the methods described herein.

[0447] One skilled in the art can readily convert the rates of isoprene production or amount of isoprene produced into any other units. Exemplary equations are listed below for interconverting between units.

Units for Rate of Isoprene production (total and specific)

Equation 3

$1 \text{ g isoprene/L}_{\text{broth}}/\text{hr} = 14.7 \text{ mmol isoprene/L}_{\text{broth}}/\text{hr}$ (total volumetric rate)

Equation 4

$1 \text{ nmol isoprene /g}_{\text{wcm}}/\text{hr} = 1 \text{ nmol isoprene /L}_{\text{broth}}/\text{hr}/\text{OD}_{600}$ (This conversion assumes that one liter of broth with an OD_{600} value of 1 has a wet cell weight of 1 gram.)

Equation 5

$1 \text{ nmol isoprene/g}_{\text{wcm}}/\text{hr} = 68.1 \text{ ng isoprene/g}_{\text{wcm}}/\text{hr}$ (given the molecular weight of isoprene)

Equation 6

$1 \text{ nmol isoprene/L}_{\text{gas}} \text{ O}_2/\text{hr} = 90 \text{ nmol isoprene/L}_{\text{broth}}/\text{hr}$ (at an O_2 flow rate of 90 L/hr per L of culture broth)

Equation 7

$1 \text{ ug isoprene/L}_{\text{gas}} \text{ isoprene in off-gas} = 60 \text{ ug isoprene/L}_{\text{broth}}/\text{hr}$ at a flow rate of 60 L_{gas} per L_{broth} (1 vvm)

Units for Titer (total and specific)

Equation 8

1 nmol isoprene/mg cell protein = 150 nmol isoprene/L_{broth}/OD₆₀₀ (This conversion assumes that one liter of broth with an OD₆₀₀ value of 1 has a total cell protein of approximately 150 mg) (specific productivity)

Equation 9

1 g isoprene/L_{broth} = 14.7 mmol isoprene/L_{broth} (total titer)

[0448] If desired, Equation 10 can be used to convert any of the units that include the wet weight of the cells into the corresponding units that include the dry weight of the cells.

Equation 10

Dry weight of cells = (wet weight of cells)/3.3

[0449] If desired, Equation 11 can be used to convert between units of ppm and ug/L. In particular, “ppm” means parts per million defined in terms of ug/g (w/w). Concentrations of gases can also be expressed on a volumetric basis using “ppmv” (parts per million by volume), defined in terms of uL/L (vol/vol). Conversion of ug/L to ppm (*e.g.*, ug of analyte per g of gas) can be performed by determining the mass per L of off-gas (*i.e.*, the density of the gas). For example, a liter of air at standard temperature and pressure (STP; 101.3 kPa (1 bar) and 273.15K) has a density of approximately 1.29 g/L. Thus, a concentration of 1 ppm (ug/g) equals 1.29 ug/L at STP (equation 11). The conversion of ppm (ug/g) to ug/L is a function of both pressure, temperature, and overall composition of the off-gas.

Equation 11

1 ppm (ug/g) equals 1.29 ug/L at standard temperature and pressure (STP; 101.3 kPa (1 bar) and 273.15K).

[0450] Conversion of ug/L to ppmv (*e.g.*, uL of analyte per L of gas) can be performed using the Universal Gas Law (equation 12). For example, an off-gas concentration of 1000 ug/L_{gas} corresponds to 14.7 umol/L_{gas}. The universal gas constant is 0.082057 L.atm K⁻¹mol⁻¹, so using equation 12, the volume occupied by 14.7 umol of HG at STP is equal to 0.329 mL. Therefore, the concentration of 1000 ug/L HG is equal to 329 ppmv or 0.0329% (v/v) at STP.

Equation 12

[0451] $PV = nRT$, where “P” is pressure, “V” is volume, “n” is moles of gas, “R” is the Universal gas constant, and “T” is temperature in Kelvin.

[0452] The amount of impurities in isoprene compositions are typically measured herein on a weight per volume (w/v) basis in units such as ug/L. If desired, measurements in units of ug/L can be converted to units of mg/m^3 using equation 13.

[0453] Equation 13

[0454] $1 \text{ ug/L} = 1 \text{ mg/m}^3$

[0455] In some embodiments encompassed by the invention, a cell comprising a heterologous nucleic acid encoding an isoprene synthase polypeptide produces an amount of isoprene that is at least or about 2-fold, 3-fold, 5-fold, 10-fold, 25-fold, 50-fold, 100-fold, 150-fold, 200-fold, 400-fold, or greater than the amount of isoprene produced from a corresponding cell grown under essentially the same conditions without the heterologous nucleic acid encoding the isoprene synthase polypeptide.

[0456] In some embodiments encompassed by the invention, a cell comprising a heterologous nucleic acid encoding an isoprene synthase polypeptide and one or more heterologous nucleic acids encoding a DXS, IDI, and/or MVA pathway polypeptide produces an amount of isoprene that is at least or about 2-fold, 3-fold, 5-fold, 10-fold, 25-fold, 50-fold, 100-fold, 150-fold, 200-fold, 400-fold, or greater than the amount of isoprene produced from a corresponding cell grown under essentially the same conditions without the heterologous nucleic acids.

[0457] In some embodiments, the isoprene composition comprises greater than or about 99.90, 99.92, 99.94, 99.96, 99.98, or 100% isoprene by weight compared to the total weight of all C5 hydrocarbons in the composition. In some embodiments, the composition has a relative detector response of greater than or about 99.90, 99.91, 99.92, 99.93, 99.94, 99.95, 99.96, 99.97, 99.98, 99.99, or 100% for isoprene compared to the detector response for all C5 hydrocarbons in the composition. In some embodiments, the isoprene composition comprises between about 99.90 to about 99.92, about 99.92 to about 99.94,

about 99.94 to about 99.96, about 99.96 to about 99.98, about 99.98 to 100% isoprene by weight compared to the total weight of all C5 hydrocarbons in the composition.

[0458] In some embodiments, the isoprene composition comprises less than or about 0.12, 0.10, 0.08, 0.06, 0.04, 0.02, 0.01, 0.005, 0.001, 0.0005, 0.0001, 0.00005, or 0.00001% C5 hydrocarbons other than isoprene (such 1,3-cyclopentadiene, *trans*-1,3-pentadiene, *cis*-1,3-pentadiene, 1,4-pentadiene, 1-pentyne, 2-pentyne, 3-methyl-1-butyne, pent-4-ene-1-yne, *trans*-pent-3-ene-1-yne, *cis*-pent-3-ene-1-yne, 3-hexen-1-ol, 3-hexen-1-yl acetate, limonene, geraniol (trans-3,7-dimethyl-2,6-octadien-1-ol) and citronellol (3,7-dimethyl-6-octen-1-ol)) by weight compared to the total weight of all C5 hydrocarbons in the composition. In some embodiments, the composition has a relative detector response of less than or about 0.12, 0.10, 0.08, 0.06, 0.04, 0.02, 0.01, 0.005, 0.001, 0.0005, 0.0001, 0.00005, or 0.00001% for C5 hydrocarbons other than isoprene compared to the detector response for all C5 hydrocarbons in the composition. In some embodiments, the composition has a relative detector response of less than or about 0.12, 0.10, 0.08, 0.06, 0.04, 0.02, 0.01, 0.005, 0.001, 0.0005, 0.0001, 0.00005, or 0.00001% for 1,3-cyclopentadiene, *trans*-1,3-pentadiene, *cis*-1,3-pentadiene, 1,4-pentadiene, 1-pentyne, 2-pentyne, 3-methyl-1-butyne, pent-4-ene-1-yne, *trans*-pent-3-ene-1-yne, *cis*-pent-3-ene-1-yne, 3-hexen-1-ol, 3-hexen-1-yl acetate, limonene, geraniol (trans-3,7-dimethyl-2,6-octadien-1-ol) and citronellol (3,7-dimethyl-6-octen-1-ol) compared to the detector response for all C5 hydrocarbons in the composition. In some embodiments, the isoprene composition comprises between about 0.02 to about 0.04%, about 0.04 to about 0.06%, about 0.06 to 0.08%, about 0.08 to 0.10%, or about 0.10 to about 0.12% C5 hydrocarbons other than isoprene (such as 1,3-cyclopentadiene, *trans*-1,3-pentadiene, *cis*-1,3-pentadiene, 1,4-pentadiene, 1-pentyne, 2-pentyne, 3-methyl-1-butyne, pent-4-ene-1-yne, *trans*-pent-3-ene-1-yne, *cis*-pent-3-ene-1-yne, 3-hexen-1-ol, 3-hexen-1-yl acetate, limonene, geraniol (trans-3,7-dimethyl-2,6-octadien-1-ol) and citronellol (3,7-dimethyl-6-octen-1-ol)) by weight compared to the total weight of all C5 hydrocarbons in the composition. .

[0459] In some embodiments, the isoprene composition comprises less than or about 50, 40, 30, 20, 10, 5, 1, 0.5, 0.1, 0.05, 0.01, or 0.005 ug/L of a compound that inhibits the polymerization of isoprene for any compound in the composition that inhibits the polymerization of isoprene. In some embodiments, the isoprene composition comprises between about 0.005 to about 50, such as about 0.01 to about 10, about 0.01 to about 5,

about 0.01 to about 1, about 0.01 to about 0.5, or about 0.01 to about 0.005 ug/L of a compound that inhibits the polymerization of isoprene for any compound in the composition that inhibits the polymerization of isoprene. In some embodiments, the isoprene composition comprises less than or about 50, 40, 30, 20, 10, 5, 1, 0.5, 0.1, 0.05, 0.01, or 0.005 ug/L of a hydrocarbon other than isoprene (such as 1,3-cyclopentadiene, *trans*-1,3-pentadiene, *cis*-1,3-pentadiene, 1,4-pentadiene, 1-pentyne, 2-pentyne, 3-methyl-1-butyne, pent-4-ene-1-yne, *trans*-pent-3-ene-1-yne, *cis*-pent-3-ene-1-yne, 3-hexen-1-ol, 3-hexen-1-yl acetate, limonene, geraniol (*trans*-3,7-dimethyl-2,6-octadien-1-ol) and citronellol (3,7-dimethyl-6-octen-1-ol)). In some embodiments, the isoprene composition comprises between about 0.005 to about 50, such as about 0.01 to about 10, about 0.01 to about 5, about 0.01 to about 1, about 0.01 to about 0.5, or about 0.01 to about 0.005 ug/L of a hydrocarbon other than isoprene. In some embodiments, the isoprene composition comprises less than or about 50, 40, 30, 20, 10, 5, 1, 0.5, 0.1, 0.05, 0.01, or 0.005 ug/L of a protein or fatty acid (such as a protein or fatty acid that is naturally associated with natural rubber).

[0460] In some embodiments, the isoprene composition comprises less than or about 10, 5, 1, 0.8, 0.5, 0.1, 0.05, 0.01, or 0.005 ppm of alpha acetylenes, piperylenes, acetonitrile, or 1,3-cyclopentadiene. In some embodiments, the isoprene composition comprises less than or about 5, 1, 0.5, 0.1, 0.05, 0.01, or 0.005 ppm of sulfur or allenes. In some embodiments, the isoprene composition comprises less than or about 30, 20, 15, 10, 5, 1, 0.5, 0.1, 0.05, 0.01, or 0.005 ppm of all acetylenes (such as pentyne-1, butyne-2, 2MB1-3yne, and 1-pentyne-4yne). In some embodiments, the isoprene composition comprises less than or about 2000, 1000, 500, 200, 100, 50, 40, 30, 20, 10, 5, 1, 0.5, 0.1, 0.05, 0.01, or 0.005 ppm of isoprene dimers, such as cyclic isoprene dimmers (*e.g.*, cyclic C10 compounds derived from the dimerization of two isoprene units).

[0461] In some embodiments, the isoprene composition includes ethanol, acetone, a C5 prenyl alcohol (such as 3-methyl-3-buten-1-ol or 3-methyl-2-buten-1-ol), or any two or more of the foregoing. In particular embodiments, the isoprene composition comprises greater than or about 0.005, 0.01, 0.05, 0.1, 0.5, 1, 5, 10, 20, 30, 40, 60, 80, 100, or 120 ug/L of ethanol, acetone, a C5 prenyl alcohol (such as 3-methyl-3-buten-1-ol or 3-methyl-2-buten-1-ol), or any two or more of the foregoing. In some embodiments, the isoprene composition comprises between about 0.005 to about 120, such as about 0.01 to about 80,

about 0.01 to about 60, about 0.01 to about 40, about 0.01 to about 30, about 0.01 to about 20, about 0.01 to about 10, about 0.1 to about 80, about 0.1 to about 60, about 0.1 to about 40, about 5 to about 80, about 5 to about 60, or about 5 to about 40 ug/L of ethanol, acetone, a C5 prenol alcohol, or any two or more of the foregoing.

[0462] In some embodiments, the isoprene composition includes one or more of the following components: 2-heptanone, 6-methyl-5-hepten-2-one, 2,4,5-trimethylpyridine, 2,3,5-trimethylpyrazine, citronellal, acetaldehyde, methanethiol, methyl acetate, 1-propanol, diacetyl, 2-butanone, 2-methyl-3-buten-2-ol, ethyl acetate, 2-methyl-1-propanol, 3-methyl-1-butanal, 3-methyl-2-butanone, 1-butanol, 2-pentanone, 3-methyl-1-butanol, ethyl isobutyrate, 3-methyl-2-butenal, butyl acetate, 3-methylbutyl acetate, 3-methyl-3-buten-1-yl acetate, 3-methyl-2-buten-1-yl acetate, (E)-3,7-dimethyl-1,3,6-octatriene, (Z)-3,7-dimethyl-1,3,6-octatriene, 2,3-cycloheptenolpyridine, or a linear isoprene polymer (such as a linear isoprene dimer or a linear isoprene trimer derived from the polymerization of multiple isoprene units). In various embodiments, the amount of one of these components relative to amount of isoprene in units of percentage by weight (*i.e.*, weight of the component divided by the weight of isoprene times 100) is greater than or about 0.01, 0.02, 0.05, 0.1, 0.5, 1, 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, or 110% (w/w). In some embodiments, the relative detector response for the second compound compared to the detector response for isoprene is greater than or about 0.01, 0.02, 0.05, 0.1, 0.5, 1, 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, or 110%. In various embodiments, the amount of one of these components relative to amount of isoprene in units of percentage by weight (*i.e.*, weight of the component divided by the weight of isoprene times 100) is between about 0.01 to about 105 % (w/w), such as about 0.01 to about 90, about 0.01 to about 80, about 0.01 to about 50, about 0.01 to about 20, about 0.01 to about 10, about 0.02 to about 50, about 0.05 to about 50, about 0.1 to about 50, or 0.1 to about 20% (w/w).

[0463] In some embodiments, the isoprene composition includes one or more of the following: an alcohol, an aldehyde, or a ketone (such as any of the alcohols, aldehydes, or ketones described herein). In some embodiments, the isoprene composition includes (i) an alcohol and an aldehyde, (ii) an alcohol and a ketone, (iii) an aldehyde and a ketone, or (iv) an alcohol, an aldehyde, and a ketone.

[0464] In some embodiments, the isoprene composition contains one or more of the following: methanol, acetaldehyde, ethanol, methanethiol, 1-butanol, 3-methyl-1-propanol,

acetone, acetic acid, 2-butanone, 2-methyl-1-butanol, or indole. In some embodiments, the isoprene composition contains 1 ppm or more of one or more of the following: methanol, acetaldehyde, ethanol, methanethiol, 1-butanol, 3-methyl-1-propanol, acetone, acetic acid, 2-butanone, 2-methyl-1-butanol, or indole. In some embodiments, the concentration of more of one or more of the following: methanol, acetaldehyde, ethanol, methanethiol, 1-butanol, 3-methyl-1-propanol, acetone, acetic acid, 2-butanone, 2-methyl-1-butanol, or indole, is between about 1 to about 10,000 ppm in an isoprene composition (such as off-gas before it is purified). In some embodiments, the isoprene composition (such as off-gas after it has undergone one or more purification steps) includes one or more of the following: methanol, acetaldehyde, ethanol, methanethiol, 1-butanol, 3-methyl-1-propanol, acetone, acetic acid, 2-butanone, 2-methyl-1-butanol, or indole, at a concentration between about 1 to about 100 ppm, such as about 1 to about 10 ppm, about 10 to about 20 ppm, about 20 to about 30 ppm, about 30 to about 40 ppm, about 40 to about 50 ppm, about 50 to about 60 ppm, about 60 to about 70 ppm, about 70 to about 80 ppm, about 80 to about 90 ppm, or about 90 to about 100 ppm. Volatile organic compounds from cell cultures (such as volatile organic compounds in the headspace of cell cultures) can be analyzed using standard methods such as those described herein or other standard methods such as proton transfer reaction-mass spectrometry (*see, for example, Bunge et al., Applied and Environmental Microbiology*, 74(7):2179-2186, 2008 which is hereby incorporated by reference in its entirety, particular with respect to the analysis of volatile organic compounds).

[0465] In some embodiments, the composition comprises greater than about 2 mg of isoprene, such as greater than or about 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 200, 300, 400, 500, 600, 700, 800, 900, or 1000 mg of isoprene. In some embodiments, the composition comprises greater than or about 2, 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100 g of isoprene. In some embodiments, the amount of isoprene in the composition is between about 2 to about 5,000 mg, such as between about 2 to about 100 mg, about 100 to about 500 mg, about 500 to about 1,000 mg, about 1,000 to about 2,000 mg, or about 2,000 to about 5,000 mg. In some embodiments, the amount of isoprene in the composition is between about 20 to about 5,000 mg, about 100 to about 5,000 mg, about 200 to about 2,000 mg, about 200 to about 1,000 mg, about 300 to about 1,000 mg, or about 400 to about 1,000 mg. In some embodiments, greater than or about 20, 25, 30, 40, 50, 60, 70, 80, 90, or 95% by weight of the volatile organic fraction of the composition is isoprene.

[0466] In some embodiments, the composition includes ethanol. In some embodiments, the composition includes between about 75 to about 90% by weight of ethanol, such as between about 75 to about 80%, about 80 to about 85%, or about 85 to about 90% by weight of ethanol. In some embodiments in which the composition includes ethanol, the composition also includes between about 4 to about 15% by weight of isoprene, such as between about 4 to about 8%, about 8 to about 12%, or about 12 to about 15% by weight of isoprene.

[0467] In some embodiments encompassed by the invention, a cell comprising one or more heterologous nucleic acids encoding an isoprene synthase polypeptide, DXS polypeptide, IDI polypeptide, and/or MVA pathway polypeptide produces an amount of an isoprenoid compound (such as a compound with 10 or more carbon atoms that is formed from the reaction of one or more IPP molecules with one or more DMAPP molecules) that is greater than or about 2-fold, 3-fold, 5-fold, 10-fold, 25-fold, 50-fold, 100-fold, 150-fold, 200-fold, 400-fold, or greater than the amount of the isoprenoid compound produced from a corresponding cell grown under essentially the same conditions without the one or more heterologous nucleic acids. In some embodiments encompassed by the invention, a cell comprising one or more heterologous nucleic acids encoding an isoprene synthase polypeptide, DXS polypeptide, IDI polypeptide, and/or MVA pathway polypeptide produces an amount of a C5 prenyl alcohol (such as 3-methyl-3-buten-1-ol or 3-methyl-2-buten-1-ol) that is greater than or about 2-fold, 3-fold, 5-fold, 10-fold, 25-fold, 50-fold, 100-fold, 150-fold, 200-fold, 400-fold, or greater than the amount of the C5 prenyl alcohol produced from a corresponding cell grown under essentially the same conditions without the one or more heterologous nucleic acids.

Exemplary Purification Methods

[0468] In some embodiments, any of the methods described herein further include recovering the compound. In some embodiments, any of the methods described herein further include recovering the isoprene or ethylene. While the exemplary purification methods below refer to isoprene, any compound disclosed herein can be purified by the methods discussed below.

[0469] The isoprene produced using the compositions and methods of the invention can be recovered using standard techniques, such as gas stripping, membrane enhanced

separation, fractionation, adsorption/desorption, pervaporation, thermal or vacuum desorption of isoprene from a solid phase, or extraction of isoprene immobilized or absorbed to a solid phase with a solvent (see, for example, U.S. Patent Nos. 4,703,007 and 4,570,029, which are each hereby incorporated by reference in their entireties, particularly with respect to isoprene recovery and purification methods). In particular, embodiments, extractive distillation with an alcohol (such as ethanol, methanol, propanol, or a combination thereof) is used to recover the isoprene. In some embodiments, the recovery of isoprene involves the isolation of isoprene in a liquid form (such as a neat solution of isoprene or a solution of isoprene in a solvent). Gas stripping involves the removal of isoprene vapor from the fermentation off-gas stream in a continuous manner. Such removal can be achieved in several different ways including, but not limited to, adsorption to a solid phase, partition into a liquid phase, or direct condensation (such as condensation due to exposure to a condensation coil or due to an increase in pressure). In some embodiments, membrane enrichment of a dilute isoprene vapor stream above the dew point of the vapor resulting in the condensation of liquid isoprene. In some embodiments, the isoprene is compressed and condensed.

[0470] The recovery of isoprene may involve one step or multiple steps. In some embodiments, the removal of isoprene vapor from the fermentation off-gas and the conversion of isoprene to a liquid phase are performed simultaneously. For example, isoprene can be directly condensed from the off-gas stream to form a liquid. In some embodiments, the removal of isoprene vapor from the fermentation off-gas and the conversion of isoprene to a liquid phase are performed sequentially. For example, isoprene may be adsorbed to a solid phase and then extracted from the solid phase with a solvent.

[0471] In some embodiments, any of the methods described herein further include purifying the isoprene. For example, the isoprene produced using the compositions and methods of the invention can be purified using standard techniques. Purification refers to a process through which isoprene is separated from one or more components that are present when the isoprene is produced. In some embodiments, the isoprene is obtained as a substantially pure liquid. Examples of purification methods include (i) distillation from a solution in a liquid extractant and (ii) chromatography. As used herein, "purified isoprene" means isoprene that has been separated from one or more components that are present when the isoprene is produced. In some embodiments, the isoprene is at least about 20%, by weight,

free from other components that are present when the isoprene is produced. In various embodiments, the isoprene is at least or about 25%, 30%, 40%, 50%, 60%, 70%, 75%, 80%, 90%, 95%, or 99%, by weight, pure. Purity can be assayed by any appropriate method, *e.g.*, by column chromatography, HPLC analysis, or GC-MS analysis.

[0472] In some embodiments, at least a portion of the gas phase remaining after one or more recovery steps for the removal of isoprene is recycled by introducing the gas phase into a cell culture system (such as a fermentor) for the production of isoprene.

[0473] In some embodiments, any of the methods described herein further include polymerizing the isoprene. For example, standard methods can be used to polymerize the purified isoprene to form *cis*-polyisoprene or other down stream products using standard methods. Accordingly, the invention also features a tire comprising polyisoprene, such as *cis*-1,4- polyisoprene and/or *trans*-1,4- polyisoprene made from any of the isoprene compositions disclosed herein.

EXAMPLES

[0474] The examples, which are intended to be purely exemplary of the invention and should therefore not be considered to limit the invention in any way, also describe and detail aspects and embodiments of the invention discussed above. Unless indicated otherwise, temperature is in degrees Centigrade and pressure is at or near atmospheric. The foregoing examples and detailed description are offered by way of illustration and not by way of limitation. All publications, patent applications, and patents cited in this specification are herein incorporated by reference as if each individual publication, patent application, or patent were specifically and individually indicated to be incorporated by reference. In particular, all publications cited herein are expressly incorporated herein by reference for the purpose of describing and disclosing compositions and methodologies which might be used in connection with the invention. Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, it will be readily apparent to those of ordinary skill in the art in light of the teachings of this invention that certain changes and modifications may be made thereto without departing from the spirit or scope of the appended claims.

Example 1: Production of isoprene in *E. coli* expressing recombinant kudzu isoprene synthase**I. Construction of vectors for expression of the kudzu isoprene synthase in *E. coli***

[0475] The protein sequence for the kudzu (*Pueraria montana*) isoprene synthase gene (IspS) was obtained from GenBank (AAQ84170). A kudzu isoprene synthase gene, optimized for *E. coli* codon usage, was purchased from DNA2.0 (SEQ ID NO:1). The isoprene synthase gene was removed from the supplied plasmid by restriction endonuclease digestion with *Bsp*LU11I/*Pst*I, gel-purified, and ligated into pTrcHis2B (Invitrogen) that had been digested with *Nco*I/*Pst*I. The construct was designed such that the stop codon in the isoprene synthase gene 5' to the *Pst*I site. As a result, when the construct was expressed the His-Tag is not attached to the isoprene synthase protein. The resulting plasmid, pTrcKudzu, was verified by sequencing (Figures 2 and 3).

[0476] The isoprene synthase gene was also cloned into pET16b (Novagen). In this case, the isoprene synthase gene was inserted into pET16b such that the recombinant isoprene synthase protein contained the N-terminal His tag. The isoprene synthase gene was amplified from pTrcKudzu by PCR using the primer set pET-His-Kudzu-2F: 5'-CGTGAGATCATATGTGTGCGACCTCTTCTCAATTAC (SEQ ID NO:3) and pET-His-Kudzu-R: 5'-CGGTCGACGGATCCCTGCAGTTAGACATACATCAGCTG (SEQ ID NO:4). These primers added an *Nde*I site at the 5'-end and a *Bam*H1 site at the 3' end of the gene respectively. The plasmid pTrcKudzu, described above, was used as template DNA, Herculanase polymerase (Stratagene) was used according to manufacture's directions, and primers were added at a concentration of 10 pMols. The PCR was carried out in a total volume of 25 µl. The PCR product was digested with *Nde*I/*Bam*H1 and cloned into pET16b digested with the same enzymes. The ligation mix was transformed into *E. coli* Top10 (Invitrogen) and the correct clone selected by sequencing. The resulting plasmid, in which the kudzu isoprene synthase gene was expressed from the T7 promoter, was designated pETNHisKudzu (Figures 4 and 5).

[0477] The kudzu isoprene synthase gene was also cloned into the low copy number plasmid pCL1920. Primers were used to amplify the kudzu isoprene synthase gene from pTrcKudzu described above. The forward primer added a *Hind*III site and an *E. coli* consensus RBS to the 5' end. The *Pst*I cloning site was already present in pTrcKudzu just

3' of the stop codon so the reverse primer was constructed such that the final PCR product includes the *Pst*I site. The sequences of the primers were: HindIII-rbs-Kudzu F: 5'-CATATGAAAGCTTGTATCGATTAAATAAGGAGGAATAAACC (SEQ ID NO:6) and BamHI-Kudzu R:

[0478] 5' - CGGTCGACGGATCCCTGCAGTTAGACATACATCAGCTG (SEQ ID NO:4).

The PCR product was amplified using Herculase polymerase with primers at a concentration of 10 pmol and with 1 ng of template DNA (pTrcKudzu). The amplification protocol included 30 cycles of (95° C for 1 minute, 60° C for 1 minute, 72° C for 2 minutes). The product was digested with *Hind*III and *Pst*I and ligated into pCL1920 which had also been digested with *Hind*III and *Pst*I. The ligation mix was transformed into *E. coli* Top10. Several transformants were checked by sequencing. The resulting plasmid was designated pCL-lac-Kudzu (Figures 6 and 7).

II. Determination of isoprene production

[0479] For the shake flask cultures, one ml of a culture was transferred from shake flasks to 20 ml CTC headspace vials (Agilent vial cat# 5188 2753; cap cat# 5188 2759). The cap was screwed on tightly and the vials incubated at the equivalent temperature with shaking at 250 rpm. After 30 minutes the vials were removed from the incubator and analyzed as described below (*see* Table 1 for some experimental values from this assay).

[0480] In cases where isoprene production in fermentors was determined, samples were taken from the off-gas of the fermentor and analyzed directly as described below (*see* Table 2 for some experimental values from this assay).

[0481] The analysis was performed using an Agilent 6890 GC/MS system interfaced with a CTC Analytics (Switzerland) CombiPAL autosampler operating in headspace mode. An Agilent HP-5MS GC/MS column (30 m x 0.25 mm; 0.25 µm film thickness) was used for separation of analytes. The sampler was set up to inject 500 µL of headspace gas. The GC/MS method utilized helium as the carrier gas at a flow of 1 ml/min. The injection port was held at 250° C with a split ratio of 50:1. The oven temperature was held at 37° C for the 2 minute duration of the analysis. The Agilent 5793N mass selective detector was run in single ion monitoring (SIM) mode on m/z 67. The detector was switched off from 1.4 to 1.7 minutes to allow the elution of permanent gases. Under these conditions isoprene (2-methyl-1,3-butadiene) was observed to elute at 1.78 minutes. A calibration table was used

to quantify the absolute amount of isoprene and was found to be linear from 1 µg/L to 2000 µg/L. The limit of detection was estimated to be 50 to 100 ng/L using this method.

III. Production of isoprene in shake flasks containing *E. coli* cells expressing recombinant isoprene synthase

[0482] The vectors described above were introduced to *E. coli* strain BL21 (Novagen) to produce strains BL21/ptrcKudzu, BL21/pCL-lac-Kudzu and BL21/pETHisKudzu. The strains were spread for isolation onto LA (Luria agar) + carbenicillin (50 µg/ml) and incubated overnight at 37° C. Single colonies were inoculated into 250 ml baffled shake flasks containing 20 ml Luria Bertani broth (LB) and carbenicillin (100 µg/ml). Cultures were grown overnight at 20° C with shaking at 200 rpm. The OD₆₀₀ of the overnight cultures were measured and the cultures were diluted into a 250 ml baffled shake flask containing 30 ml MagicMedia (Invitrogen) + carbenicillin (100 µg/ml) to an OD₆₀₀ ~ 0.05. The culture was incubated at 30° C with shaking at 200 rpm. When the OD₆₀₀ ~ 0.5 - 0.8, 400 µM IPTG was added and the cells were incubated for a further 6 hours at 30° C with shaking at 200 rpm. At 0, 2, 4 and 6 hours after induction with IPTG, 1 ml aliquots of the cultures were collected, the OD₆₀₀ was determined and the amount of isoprene produced was measured as described above. Results are shown in Figure 8.

IV. Production of Isoprene from BL21/ptrcKudzu in 14 liter fermentation

[0483] Large scale production of isoprene from *E. coli* containing the recombinant kudzu isoprene synthase gene was determined from a fed-batch culture. The recipe for the fermentation media (TM2) per liter of fermentation medium was as follows: K₂HPO₄ 13.6 g, KH₂PO₄ 13.6 g, MgSO₄ * 7H₂O 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, (NH₄)₂SO₄ 3.2 g, yeast extract 5 g, 1000X Modified Trace Metal Solution 1 ml. All of the components were added together and dissolved in diH₂O. The pH was adjusted to 6.8 with potassium hydroxide (KOH) and q.s. to volume. The final product was filter sterilized with 0.22 µ filter (only, do not autoclave). The recipe for 1000X Modified Trace Metal Solution was as follows: Citric Acids * H₂O 40 g, MnSO₄ * H₂O 30 g, NaCl 10 g, FeSO₄ * 7H₂O 1 g, CoCl₂ * 6H₂O 1 g, ZnSO * 7H₂O 1 g, CuSO₄ * 5H₂O 100 mg, H₃BO₃ 100 mg, NaMoO₄ * 2H₂O 100 mg. Each component was dissolved one at a time in diH₂O, pH to 3.0 with HCl/NaOH, then q.s. to volume and filter sterilized with a 0.22 µ filter.

[0484] This experiment was carried out in 14 L bioreactor to monitor isoprene formation from glucose at the desired fermentation, pH 6.7 and temperature 34° C. An inoculum of *E. coli* strain BL21/pTrcKudzu taken from a frozen vial was prepared in soytone-yeast extract-glucose medium. After the inoculum grew to OD₅₅₀ = 0.6, two 600 ml flasks were centrifuged and the contents resuspended in 70 ml supernatant to transfer the cell pellet (70 ml of OD 3.1 material) to the bioreactor. At various times after inoculation, samples were removed and the amount of isoprene produced was determined as described above. Results are shown in Figure 9.

Example 2: Production of isoprene in *E. coli* expressing recombinant poplar isoprene synthase

[0485] The protein sequence for the poplar (*Populus alba* x *Populus tremula*) isoprene synthase (Schnitzler, J-P, *et al.* (2005) *Planta* 222:777-786) was obtained from GenBank (CAC35696). A gene, codon optimized for *E. coli*, was purchased from DNA2.0 (p9796-poplar, Figures 30 and 31). The isoprene synthase gene was removed from the supplied plasmid by restriction endonuclease digestion with *Bsp*LU11I/*Pst*I, gel-purified, and ligated into pTrcHis2B that had been digested with *Nco*I/*Pst*I. The construct is cloned such that the stop codon in the insert is before the *Pst*I site, which results in a construct in which the His-Tag is not attached to the isoprene synthase protein. The resulting plasmid pTrcPoplar (Figures 32 and 33), was verified by sequencing.

[0486] Example 2B: Demonstration of isoprene synthase activity from several *populus* isoprene synthases

[0487] The following isoprene synthases were examined; *Populus alba* (Accession number BAD98243; Figures 137A and B; SEQ ID NO:109), *Populus nigra* (Accession number CAL69918; Figures 137C and D; SEQ ID NO:110), *Populus tremuloides* (Accession number AAQ16588; Figure 137 E, F, and G; SEQ ID NO:123), *Populus trichocarpa* (Accession number ACD70404; Figures 137H and I; SEQ ID NO:111), *Populus alba* x *Populus tremula* (Accession number CAJ29303; Figures 137J and K; SEQ ID NO:112), and MCM112-Kudzu.

[0488] pET24Kudzu (also referred to as MCM112) was constructed as follows: the kudzu isoprene synthase gene was subcloned into the pET24d vector (Novagen) from the pCR2.1 vector (Invitrogen). The kudzu IspS gene was amplified from pTrcKudzu template DNA

using primers MCM50 5'-GATCATGCAT TCGCCCTTAG GAGGTAAAAAACATGTGTGCGACCTCTTC TCAATTTACT (SEQ ID NO:31); and MCM53 5'-CGGTCGACGGATCCCTGCAG TTAGACATAC ATCAGCTG (SEQ ID NO:32). PCR reactions were carried out using Taq DNA Polymerase (Invitrogen), and the resulting PCR product was cloned into pCR2.1-TOPO TA cloning vector (Invitrogen), and transformed into *E. coli* Top10 chemically competent cells (Invitrogen). Transformants were plated on L-agar containing carbenicillin (50 µg/ml) and incubated overnight at 37°C. Five ml Luria Broth cultures containing carbenicillin 50 µg/ml were inoculated with single transformants and grown overnight at 37°C. Five colonies were screened for the correct insert by sequencing of plasmid DNA isolated from 1 ml of liquid culture (Luria Broth) and purified using the QIAprep Spin Mini-prep Kit (Qiagen). The resulting plasmid, designated MCM93, contains the kudzu IspS coding sequence in a pCR2.1 backbone (Figure 137L). The sequence of MCM93 (SEQ ID NO:113) is shown in Figures 137M and N.

[0489] The kudzu coding sequence was removed by restriction endonuclease digestion with *Pci*I and *Bam*H1 (Roche) and gel purified using the QIAquick Gel Extraction kit (Qiagen). The pET24d vector DNA was digested with *Nco*I and *Bam*HI (Roche), treated with shrimp alkaline phosphatase (Roche), and purified using the QIAprep Spin Mini-prep Kit (Qiagen). The kudzu IspS fragment was ligated to the *Nco*I/*Bam*H1 digested pET24d using the Rapid DNA Ligation Kit (Roche) at a 5:1 fragment to vector ratio in a total volume of 20 µl. A portion of the ligation mixture (5 µl) was transformed into *E. coli* Top 10 chemically competent cells and plated on L agar containing kanamycin (50 µg/ml). The correct transformant was confirmed by sequencing and transformed into chemically competent BL21(λDE3)pLysS cells (Novagen). A single colony was selected after overnight growth at 37°C on L agar containing kanamycin (50 µg/ml). A map of the resulting plasmid designated as pET24D-Kudzu is shown in Figure 137O. The sequence of pET24D-Kudzu (SEQ ID NO:114) is shown in Figures 137P and Q.

[0490] *Escherichia coli* optimized isoprene synthase genes cloned into the pET24a expression vector (Novagen) were purchased from DNA2.0 (Menlo Park, CA) for *Populus tremuloides*, *Populus alba*, *Populus nigra* and *Populus trichocarpa*. Genes were synthesized with the chloroplast transit peptide sequence removed, resulting in expression of mature proteins.

[0491] The construct for the Kudzu isoprene synthase was used as control in this example.

The plasmids were transformed into the *E. coli* expression host BL21(DE3)plysS and transformants were grown in 0.6 ml TM3 medium. The recipe for TM3 medium is as follows: K_2HPO_4 (13.6 g/l) KH_2PO_4 (13.6 g/l), $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ (2 g/L) Citric Acid Monohydrate (2 g/L) Ferric Ammonium Citrate (0.3 g/L) $(\text{NH}_4)_2\text{SO}_4$ (3.2 g/L) yeast extract (0.2 g/L) 1 ml of 1000x Trace Elements solution, pH adjusted to 6.8 with ammonium hydroxide qs to volume with sterile DI H_2O and filter sterilized with a 0.22 micron filter. The recipe for 1000X Trace Elements solution is as follows: Citric Acids * H_2O (40 g/L), $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ (30 g/L), NaCl (10 g/L), $\text{FeSO}_4 \cdot 7 \text{H}_2\text{O}$ (1 g/L), $\text{CoCl}_2 \cdot 6 \text{H}_2\text{O}$ (1 g/L), $\text{ZnSO}_4 \cdot 7 \text{H}_2\text{O}$ (1 g/L), $\text{CuSO}_4 \cdot 5 \text{H}_2\text{O}$ (100 mg/L), H_3BO_3 (100 mg/L), $\text{NaMoO}_4 \cdot 2 \text{H}_2\text{O}$ (100 mg/L). Each component was dissolved one at a time in DI H_2O , pH adjusted to 3.0 with HCl/NaOH, qs to volume and filter sterilized with a 0.22 micron filter.

[0492] The cultures were induced with 400 μM IPTG and growth was continued to OD_{600} of about 5. Aliquots of culture were transferred to a deep well glass plate and wells were sealed with aluminum plate sealer. The plate was incubated at 25°C for 30 minutes with shaking at 450 rpm. The reactions were heat inactivated by raising the temperature to 70°C for 5 minutes. Whole cell head space was measured by the GCMS method as described in Example 1, Part II.

[0493] K_m values were obtained from cultures grown in similar manner but cells were harvested and lysed by a freeze/thaw lysozyme protocol. A volume of 400 μL of culture was transferred into a new 96-well plate (Perkin Elmer, Catalog No. 6008290) and cells were harvested by centrifugation in a Beckman Coulter Allegra 6R centrifuge at 2500 x g. The pellet was resuspended in 200 μL of hypotonic buffer (5 mM MgCl_2 , 5 mM Tris HCl, 5 mM DTT pH 8.0) and the plate was frozen at -80°C for a minimum time of 60 minutes. Cell lysate was prepared by thawing the plate and adding 32 μL of isoprene synthase DMAPP assay buffer (57 mM Tris HCl, 19 mM MgCl_2 , 74 mg/mL DNase I (Sigma Catalog No. DN-25), 2.63×10^5 U/mL of ReadyLyse lysozyme solution (Epicentre Catalog No. R1802M), and 5 mg/mL of molecular biology grade BSA. The plate was incubated with shaking at 25°C for 30 minutes and then placed on ice. DMAPP and lysate were added at desired concentration in a sealed deep well glass block for the whole cell head space assay described above. The reactions were allowed to proceed for 1 hour and

then terminated by the heat step described above and head space activity was measured also as described.

[0494] In an alternate approach, the activity of the enzymes was measured from cells cultured in 25 mL volume and induced similarly as described above. Cells were harvested by centrifugation and the pellets were lysed by French pressing in buffer consisting of 50% glycerol mixed 1:1 with 20 mM Tris/HCl pH 7.4, 20 mM MgCl₂, 200 mM KCl, 1 mM DTT. A lysate volume of 25 uL was assayed for isoprene synthase activity in 2 mL screw cap vials containing 75 uL of assay buffer (66.6 mM Tris/HCl pH 8, 6.66 mM DMAPP, 43 mM, MgCl₂). The reaction was incubated for 15 minutes at 30°C and was quenched by the addition of 100 uL of 250 mM EDTA through the septum of the vial. Isoprene was measured by GC/MS as described in Example 1, Part II.

[0495] All methods for the determination of activity showed that the poplar enzyme derived from the pure bred poplars were several-fold higher than the *Populus* [*alba x tremula*]. Figures 138 and 139 showed these results for the whole cell head space assay and the DMAPP assay, respectively, and surprisingly indicate that enzymes from *P. nigra*, *P. tremuloides*, *P. trichocarpa*, and *P. alba* all had significantly higher activity than hybrid [*P. alba x P.tremula*].

[0496] The DMAPP assay was performed as follows: a volume of 400 µL of culture was transferred into a new 96-well plate (Perkin Elmer, Catalog No. 6008290) and cells were harvested by centrifugation in a Beckman Coulter Allegra 6R centrifuge at 2500 x g. The pellet was resuspended in 200 mL of hypotonic buffer (5 mM MgCl₂, 5 mM Tris HCl, 5 mM DTT pH 8.0) and the plate was frozen at -80°C for a minimum time of 60 minutes. Cell lysate was prepared by thawing the plate and adding 32 mL of isoprene synthase DMAPP assay buffer (57 mM Tris HCl, 19 mM MgCl₂, 74 mg/mL DNase I (Sigma Catalog No. DN-25), 2.63x10⁵ U/mL of ReadyLyse lysozyme solution (Epicentre Catalog No. R1802M), and 5 mg/mL of molecular biology grade BSA. The plate was incubated with shaking at 25°C for 30 minutes and then placed on ice. For isoprene production an 80 mL aliquot of lysate was transferred to a 96-deep well glass plate (Zinsser Catalog No. 3600600) and 20 mL of a 10 mM DMAPP solution in 100 mM KHPO₄, pH 8.2 (Cayman Chemical Catalog No. 63180) was added. The plate was sealed with an aluminum plate seal (Beckman Coulter Catalog No. 538619) and incubated with shaking at 30°C for 60 minutes. The enzymatic reactions were terminated by heating the glass block (70°C for 5

minutes). The cell head space of each well was quantitatively analyzed as described in Example 1, Part II.

[0497] Notably, *P. alba*, *P. tremuloides*, *P. trichocarpa* had higher activity than the isoprene synthase from Kudzu. The enzyme from *P. alba* was expressed with the greatest activity of all enzymes tested. The higher activities observed with the cell lysate compared to the whole cell head space assay was likely due to limitations in DMAPP, the substrate for these enzymes, delivered by the endogenous deoxyxylulose 5-phosphate (DXP) pathway of the cell.

[0498] K_m kinetic parameter was measured to be about 2 to 3 mM for all enzymes for which the value was determined.

Example 3: Production of isoprene in *Pantoea citrea* expressing recombinant kudzu isoprene synthase

[0499] The pTrcKudzu and pCL-lac Kudzu plasmids described in Example 1 were electroporated into *P. citrea* (U.S. Pat. No. 7,241,587). Transformants were selected on LA containing carbenicillin (200 µg/ml) or spectinomycin (50 µg/ml) respectively. Production of isoprene from shake flasks and determination of the amount of isoprene produced was performed as described in Example 1 for *E. coli* strains expressing recombinant kudzu isoprene synthase. Results are shown in Figure 10.

Example 4: Production of isoprene in *Bacillus subtilis* expressing recombinant kudzu isoprene synthase

I. Construction of a *B. subtilis* replicating plasmid for the expression of kudzu isoprene synthase

[0500] The kudzu isoprene synthase gene was expressed in *Bacillus subtilis aprEnprE Pxyl-comK* strain (BG3594comK) using a replicating plasmid (pBS19 with a chloramphenicol resistance cassette) under control of the *aprE* promoter. The isoprene synthase gene, the *aprE* promoter and the transcription terminator were amplified separately and fused using PCR. The construct was then cloned into pBS19 and transformed into *B. subtilis*.

a) Amplification of the *aprE* promoter

[0501] The *aprE* promoter was amplified from chromosomal DNA from *Bacillus subtilis* using the following primers:

CF 797 (+) Start *aprE* promoter MfeI

5'- GACATCAATTGCTCCATTTTCTTCTGCTATC (SEQ ID NO:58)

CF 07-43 (-) Fuse *aprE* promoter to Kudzu *ispS*

5'- ATTGAGAAGAGGTCGCACACACTCTTTACCCTCTCCTTTTA (SEQ ID NO:59)

b) Amplification of the isoprene synthase gene

[0502] The kudzu isoprene synthase gene was amplified from plasmid pTrcKudzu (SEQ ID NO:2). The gene had been codon optimized for *E. coli* and synthesized by DNA 2.0. The following primers were used:

CF 07-42 (+) Fuse the *aprE* promoter to kudzu isoprene synthase gene (GTG start codon)

5'- TAAAAGGAGAGGGTAAAGAGTGTGTGCGACCTCTTCTCAAT (SEQ ID NO:60)

CF 07-45 (-) Fuse the 3' end of kudzu isoprene synthase gene to the terminator

5'- CCAAGGCCGGTTTTTTTTTAGACATACATCAGCTGGTTAATC (SEQ ID NO:61)

c) Amplification of the transcription terminator

[0503] The terminator from the alkaline serine protease of *Bacillus amyliquefaciens* was amplified from a previously sequenced plasmid pJHPms382 using the following primers:

CF 07-44 (+) Fuse the 3' end of kudzu isoprene synthase to the terminator

5'- GATTAACCAGCTGATGTATGTCTAAAAAAAACCGGCCTTGG (SEQ ID NO:62)

CF 07-46 (-) End of *B. amyliquefaciens* terminator (BamHI)

5'- GACATGACGGATCCGATTACGAATGCCGTCTC (SEQ ID NO:63)

[0504] The kudzu fragment was fused to the terminator fragment using PCR with the following primers:

CF 07-42 (+) Fuse the *aprE* promoter to kudzu isoprene synthase gene (GTG start codon)

5'- TAAAAGGAGAGGGTAAAGAGTGTGTGCGACCTCTTCTCAAT (SEQ ID NO:61)

CF 07-46 (-) End of *B. amyliquefaciens* terminator (BamHI)

5'- GACATGACGGATCCGATTACGAATGCCGTCTC (SEQ ID NO:63)

[0505] The kudzu-terminator fragment was fused to the promoter fragment using PCR with the following primers:

CF 797 (+) Start *aprE* promoter MfeI

5'- GACATCAATTGCTCCATTTTCTTCTGCTATC (SEQ ID NO:64)

CF 07-46 (-) End of *B. amyliquefaciens* terminator (BamHI)

5'- GACATGACGGATCCGATTACGAATGCCGTCTC (SEQ ID NO:63)

[0506] The fusion PCR fragment was purified using a Qiagen kit and digested with the restriction enzymes *MfeI* and *BamHI*. This digested DNA fragment was gel purified using a Qiagen kit and ligated to a vector known as pBS19, which had been digested with *EcoRI* and *BamHI* and gel purified.

[0507] The ligation mix was transformed into *E. coli* Top 10 cells and colonies were selected on LA+50 carbenicillin plates. A total of six colonies were chosen and grown overnight in LB+50 carbenicillin and then plasmids were isolated using a Qiagen kit. The plasmids were digested with *EcoRI* and *BamHI* to check for inserts and three of the correct plasmids were sent in for sequencing with the following primers:

CF 149 (+) *EcoRI* start of *aprE* promoter

5'- GACATGAATTCCTCCATTTTCTTCTGC (SEQ ID NO:65)

CF 847 (+) Sequence in pXX 049 (end of *aprE* promoter)

5'- AGGAGAGGGTAAAGAGTGAG (SEQ ID NO:66)

CF 07-45 (-) Fuse the 3' end of kudzu isoprene synthase to the terminator

5'- CCAAGGCCGGTTTTTTTTTAGACATACATCAGCTGGTTAATC (SEQ ID NO:61)

CF 07-48 (+) Sequencing primer for kudzu isoprene synthase

5'- CTTTTCATCACCCACCTGAAG (SEQ ID NO:67)

CF 07-49 (+) Sequencing in kudzu isoprene synthase

5'- GGCGAAATGGTCCAACAACAAAATTATC (SEQ ID NO:68)

[0508] The plasmid designated pBS Kudzu #2 (Figures 52 and 12) was correct by sequencing and was transformed into BG 3594 comK, a *Bacillus subtilis* host strain. Selection was done on LA + 5 chloramphenicol plates. A transformant was chosen and struck to single colonies on LA + 5 chloramphenicol, then grown in LB+5 chloramphenicol until it reached an OD₆₀₀ of 1.5. It was stored frozen in a vial at -80° C in the presence of glycerol. The resulting strain was designated CF 443.

II. Production of isoprene in shake flasks containing *B. subtilis* cells expressing recombinant isoprene synthase

[0509] Overnight cultures were inoculated with a single colony of CF 443 from a LA + Chloramphenicol (Cm, 25 µg/ml). Cultures were grown in LB + Cm at 37° C with shaking at 200 rpm. These overnight cultures (1 ml) were used to inoculate 250 ml baffled shake flasks containing 25 ml Grants II media and chloramphenicol at a final concentration of 25 µg/ml. Grants II Media recipe was 10 g soytone, 3 ml 1M K₂HPO₄, 75 g glucose, 3.6 g urea, 100 ml 10X MOPS, q.s. to 1 L with H₂O, pH 7.2; 10X MOPS recipe was 83.72 g MOPS, 7.17 g tricine, 12 g KOH pellets, 10 ml 0.276M K₂SO₄ solution, 10 ml 0.528M MgCl₂ solution, 29.22 g NaCl, 100 ml 100X micronutrients, q.s. to 1 L with H₂O; and 100X micronutrients recipe was 1.47 g CaCl₂*2H₂O, 0.4 g FeSO₄*7H₂O, 0.1 g MnSO₄*H₂O, 0.1 g ZnSO₄*H₂O, 0.05 g CuCl₂*2H₂O, 0.1 g CoCl₂*6H₂O, 0.1 g Na₂MoO₄*2H₂O, q.s. to 1 L with H₂O. Shake flasks were incubated at 37° C and samples were taken at 18, 24, and 44 hours. At 18 hours the headspaces of CF443 and the control strain were sampled. This represented 18 hours of accumulation of isoprene. The amount of isoprene was determined by gas chromatography as described in Example 1. Production of isoprene was enhanced significantly by expressing recombinant isoprene synthase (Figure 11).

III. Production of isoprene by CF443 in 14 L fermentation

[0510] Large scale production of isoprene from *B. subtilis* containing the recombinant kudzu isoprene synthase gene on a replication plasmid was determined from a fed-batch culture. *Bacillus* strain CF 443, expressing a kudzu isoprene synthase gene, or control strain which does not express a kudzu isoprene synthase gene were cultivated by conventional fed-batch fermentation in a nutrient medium containing soy meal (Cargill), sodium and potassium phosphate, magnesium sulfate and a solution of citric acid, ferric chloride and manganese chloride. Prior to fermentation the media is macerated for 90 minutes using a mixture of enzymes including cellulases, hemicellulases and pectinases (see, WO95/04134). 14-L batch fermentations are fed with 60% wt/wt glucose (Cargill DE99 dextrose, ADM Versadex greens or Danisco invert sugar) and 99% wt/wt oil (Western Family soy oil, where the 99% wt/wt is the concentration of oil before it was added to the cell culture medium). Feed was started when glucose in the batch was non-detectable. The feed rate was ramped over several hours and was adjusted to add oil on an equal carbon basis. The pH was controlled at 6.8 – 7.4 using 28% w/v ammonium hydroxide. In case of foaming, antifoam agent was added to the media. The fermentation temperature was controlled at 37°C and the fermentation culture was agitated at 750 rpm. Various other parameters such as pH, DO%, airflow, and pressure were monitored throughout the entire process. The DO% is maintained above 20. Samples were taken over the time course of 36 hours and analyzed for cell growth (OD₅₅₀) and isoprene production. Results of these experiments are presented in Figures 53A and 53B.

IV. Integration of the kudzu isoprene synthase (ispS) in *B. subtilis*.

[0511] The kudzu isoprene synthase gene was cloned in an integrating plasmid (pJH101-cmpR) under the control of the *aprE* promoter. Under the conditions tested, no isoprene was detected.

Example 5: Production of isoprene in *Trichoderma*

I. Construction of vectors for expression of the kudzu isoprene synthase in *Trichoderma reesei*

[0512] The *Yarrowia lipolytica* codon-optimized kudzu IS gene was synthesized by DNA 2.0 (SEQ ID NO:8) (Figure 13). This plasmid served as the template for the following PCR

amplification reaction: 1 µl plasmid template (20 ng/ul), 1 µl Primer EL-945 (10 uM) 5'-GCTTATGGATCCTCTAGACTATTACACGTACATCAATTGG (SEQ ID NO:9), 1 µl Primer EL-965 (10uM) 5'-CACCATGTGTGCAACCTCCTCCCAGTTTAC (SEQ ID NO:10), 1 µl dNTP (10mM), 5 µl 10x PfuUltra II Fusion HS DNA Polymerase Buffer, 1 µl PfuUltra II Fusion HS DNA Polymerase, 40 µl water in a total reaction volume of 50 µl. The forward primer contained an additional 4 nucleotides at the 5'-end that did not correspond to the *Y. lipolytica* codon-optimized kudzu isoprene synthase gene, but was required for cloning into the pENTR/D-TOPO vector. The reverse primer contained an additional 21 nucleotides at the 5'-end that did not correspond to the *Y. lipolytica* codon-optimized kudzu isoprene synthase gene, but were inserted for cloning into other vector backbones. Using the MJ Research PTC-200 Thermocycler, the PCR reaction was performed as follows: 95° C for 2 minutes (first cycle only), 95° C for 30 seconds, 55° C for 30 seconds, 72° C for 30 seconds (repeat for 27 cycles), 72° C for 1 minute after the last cycle. The PCR product was analyzed on a 1.2% E-gel to confirm successful amplification of the *Y. lipolytica* codon-optimized kudzu isoprene synthase gene.

[0513] The PCR product was then cloned using the TOPO pENTR/D-TOPO Cloning Kit following manufacturer's protocol: 1 µl PCR reaction, 1 µl Salt solution, 1 µl TOPO pENTR/D-TOPO vector and 3 µl water in a total reaction volume of 6 µl. The reaction was incubated at room temperature for 5 minutes. One microliter of TOPO reaction was transformed into TOP10 chemically competent *E. coli* cells. The transformants were selected on LA + 50 µg/ml kanamycin plates. Several colonies were picked and each was inoculated into a 5 ml tube containing LB + 50 µg/ml kanamycin and the cultures grown overnight at 37° C with shaking at 200 rpm. Plasmids were isolated from the overnight culture tubes using QIAprep Spin Miniprep Kit, following manufacturer's protocol. Several plasmids were sequenced to verify that the DNA sequence was correct.

[0514] A single pENTR/D-TOPO plasmid, encoding a *Y. lipolytica* codon-optimized kudzu isoprene synthase gene, was used for Gateway Cloning into a custom-made pTrex3g vector. Construction of pTrex3g is described in WO 2005/001036 A2. The reaction was performed following manufacturer's protocol for the Gateway LR Clonase II Enzyme Mix Kit (Invitrogen): 1 µl *Y. lipolytica* codon-optimized kudzu isoprene synthase gene pENTR/D-TOPO donor vector, 1 µl pTrex3g destination vector, 6 µl TE buffer, pH 8.0 in a total reaction volume of 8 µl. The reaction was incubated at room temperature for 1 hour

and then 1 µl proteinase K solution was added and the incubation continued at 37° C for 10 minutes. Then 1 µl of reaction was transformed into TOP10 chemically competent *E. coli* cells. The transformants were selected on LA + 50 µg/ml carbenicillin plates. Several colonies were picked and each was inoculated into a 5 ml tube containing LB + 50 µg/ml carbenicillin and the cultures were grown overnight at 37° C with shaking at 200 rpm. Plasmids were isolated from the overnight culture tubes using QIAprep Spin Miniprep Kit (Qiagen, Inc.), following manufacturer's protocol. Several plasmids were sequenced to verify that the DNA sequence was correct.

[0515] Biolistic transformation of *Y. lipolytica* codon-optimized kudzu isoprene synthase pTrex3g plasmid (Figure 14) into a quad delete *Trichoderma reesei* strain was performed using the Biolistic PDS-1000/HE Particle Delivery System (see WO 2005/001036 A2). Isolation of stable transformants and shake flask evaluation was performed using protocol listed in Example 11 of patent publication WO 2005/001036 A2.

II. Production of isoprene in recombinant strains of *T. reesei*

[0516] One ml of 15 and 36 hour old cultures of isoprene synthase transformants described above were transferred to head space vials. The vials were sealed and incubated for 5 hours at 30° C. Head space gas was measured and isoprene was identified by the method described in Example 1. Two of the transformants showed traces of isoprene. The amount of isoprene could be increased by a 14 hour incubation. The two positive samples showed isoprene at levels of about 0.5 µg/L for the 14 hour incubation. The untransformed control showed no detectable levels of isoprene. This experiment shows that *T. reesei* is capable of producing isoprene from endogenous precursor when supplied with an exogenous isoprene synthase.

Example 6: Production of isoprene in *Yarrowia*

I. Construction of vectors for expression of the kudzu isoprene synthase in *Yarrowia lipolytica*.

[0517] The starting point for the construction of vectors for the expression of the kudzu isoprene synthase gene in *Yarrowia lipolytica* was the vector pSPZ1(MAP29Spb). The complete sequence of this vector (SEQ ID No:11) is shown in Figure 15.

[0518] The following fragments were amplified by PCR using chromosomal DNA of a *Y. lipolytica* strain GICC 120285 as the template: a promotorless form of the URA3 gene, a fragment of 18S ribosomal RNA gene, a transcription terminator of the *Y. lipolytica* XPR2 gene and two DNA fragments containing the promoters of XPR2 and ICL1 genes. The following PCR primers were used:

ICL1 3

5'- GGTGAATTCAGTCTACTGGGGATTCCCAAATCTATATATACTGCAGGTGAC
(SEQ ID NO:69)

ICL1 5

5'- GCAGGTGGGAAACTATGCACTCC (SEQ ID NO:70)

XPR 3

5'- CCTGAATTCTGTTGGATTGGAGGATTGGATAGTGGG (SEQ ID NO:71)

XPR 5

5'- GGTGTCGACGTACGGTCGAGCTTATTGACC (SEQ ID NO:72)

XPRT3

5'- GGTGGGCCCCGCATTTTGCCACCTACAAGCCAG (SEQ ID NO:73)

XPRT 5

5'- GGTGAATTCTAGAGGATCCCAACGCTGTTGCCTACAACGG (SEQ ID NO:74)

Y18S3

5'- GGTGCGGCCGCTGTCTGGACCTGGTGAGTTTCCCCG (SEQ ID NO:75)

Y18S 5

5'- GGTGGGCCCATTAAATCAGTTATCGTTTATTGATAG (SEQ ID NO:76)

YURA3

5'- GGTGACCAGCAAGTCCATGGGTGGTTTGATCATGG (SEQ ID NO:77)

YURA 50

5'-GGTGCGGCCGCCTTTGGAGTACGACTCCAACATG (SEQ ID NO:78)

YURA 51

5'-GCGGCCGCAGACTAAATTTATTTTCAGTCTCC (SEQ ID NO:79)

[0519] For PCR amplification the PfuUltraII polymerase (Stratagene), supplier-provided buffer and dNTPs, 2.5 μ M primers and the indicated template DNA were used as per the manufacturer's instructions. The amplification was done using the following cycle: 95° C for 1 min; 34x (95° C for 30 sec; 55° C for 30 sec; 72° C for 3 min) and 10 min at 72° C followed by a 4° C incubation.

[0520] Synthetic DNA molecules encoding the kudzu isoprene synthase gene, codon-optimized for expression in *Yarrowia*, was obtained from DNA 2.0 (Figure 16; SEQ ID NO:12). Full detail of the construction scheme of the plasmids pYLA(KZ1) and pYLI(KZ1) carrying the synthetic kudzu isoprene synthase gene under control of XPR2 and ICL1 promoters respectively is presented in Figure 18. Control plasmids in which a mating factor gene (MAP29) is inserted in place of an isoprene synthase gene were also constructed (Figure 18E and 18F).

[0521] A similar cloning procedure can be used to express a poplar (*Populus alba* x *Populus tremula*) isoprene synthase gene. The sequence of the poplar isoprene is described in Miller B. *et al.* (2001) *Planta* 213, 483-487 and shown in Figure 17 (SEQ ID NO:13). A construction scheme for the generation the plasmids pYLA(POP1) and pYLI(POP1) carrying synthetic poplar isoprene synthase gene under control of XPR2 and ICL1 promoters respectively is presented in Figure 18A and B.

II. Production of isoprene by recombinant strains of *Y. lipolytica*.

[0522] Vectors pYLA(KZ1), pYLI(KZ1), pYLA(MAP29) and pYLI(MAP29) were digested with *Sac*II and used to transform the strain *Y. lipolytica* CLIB 122 by a standard lithium acetate/polyethylene glycol procedure to uridine prototrophy. Briefly, the yeast cells grown in YEPD (1% yeast extract, 2% peptone, 2% glucose) overnight, were collected by centrifugation (4000 rpm, 10 min), washed once with sterile water and suspended in 0.1 M lithium acetate, pH 6.0. Two hundred μ l aliquots of the cell suspension were mixed with

linearized plasmid DNA solution (10-20 µg), incubated for 10 minutes at room temperature and mixed with 1 ml of 50% PEG 4000 in the same buffer. The suspensions were further incubated for 1 hour at room temperature followed by a 2 minutes heat shock at 42° C. Cells were then plated on SC his leu plates (0.67% yeast nitrogen base, 2% glucose, 100 mg/L each of leucine and histidine). Transformants appeared after 3-4 days of incubation at 30° C.

[0523] Three isolates from the pYLA(KZ1) transformation, three isolates from the pYLI(KZ1) transformation, two isolates from the pYLA(MAP29) transformation and two isolates from the pYLI(MAP29) transformation were grown for 24 hours in YEP7 medium (1% yeast extract, 2% peptone, pH 7.0) at 30° C with shaking. Cells from 10 ml of culture were collected by centrifugation, resuspended in 3 ml of fresh YEP7 and placed into 15 ml screw cap vials. The vials were incubated overnight at room temperature with gentle (60 rpm) shaking. Isoprene content in the headspace of these vials was analyzed by gas chromatography using mass-spectrometric detector as described in Example 1. All transformants obtained with pYLA(KZ1) and pYLI(KZ1) produced readily detectable amounts of isoprene (0.5 µg/L to 1 µg/L, Figure 20). No isoprene was detected in the headspace of the control strains carrying phytase gene instead of an isoprene synthase gene.

Example 7: Production of isoprene in *E. coli* expressing kudzu isoprene synthase and *idi*, or *dxs*, or *idi* and *dxs*

I. Construction of vectors encoding kudzu isoprene synthase and *idi*, or *dxs*, or *idi* and *dxs* for the production of isoprene in *E. coli*

i) Construction of pTrcKudzuKan

[0524] The *bla* gene of pTrcKudzu (described in Example 1) was replaced with the gene conferring kanamycin resistance. To remove the *bla* gene, pTrcKudzu was digested with *Bsp*HI, treated with Shrimp Alkaline Phosphatase (SAP), heat killed at 65° C, then end-filled with Klenow fragment and dNTPs. The 5 kbp large fragment was purified from an agarose gel and ligated to the kan^r gene which had been PCR amplified from pCR-Blunt-II-TOPO using primers MCM22 5'- GATCAAGCTTAACCGGAATTGCCAGCTG (SEQ ID NO:14) and MCM23 5'- GATCCGATCGTCAGAAGAAGCTCGTCAAGAAGGC (SEQ ID NO:15), digested with *Hind*III and *Pvu*I, and end-filled. A transformant carrying

a plasmid conferring kanamycin resistance (pTrcKudzuKan) was selected on LA containing kanamycin 50 µg/ml.

ii) Construction of pTrcKudzu yIDI Kan

[0525] pTrcKudzuKan was digested with *Pst*I, treated with SAP, heat killed and gel purified. It was ligated to a PCR product encoding *idi* from *S. cerevisiae* with a synthetic RBS. The primers for PCR were NsiI-YIDI 1 F 5'-CATCAATGCATCGCCCTTAGGAGGTAAAAAAAATGAC (SEQ ID NO:16) and PstI-YIDI 1 R 5'-CCTTCTGCAGGACGCGTTGTTATAGC (SEQ ID NO:17); and the template was *S. cerevisiae* genomic DNA. The PCR product was digested with *Nsi*I and *Pst*I and gel purified prior to ligation. The ligation mixture was transformed into chemically competent TOP10 cells and selected on LA containing 50 µg/ml kanamycin. Several transformants were isolated and sequenced and the resulting plasmid was called pTrcKudzu-yIDI(kan) (Figures 34 and 35).

iii) Construction of pTrcKudzu DXS Kan

[0526] Plasmid pTrcKudzuKan was digested with *Pst*I, treated with SAP, heat killed and gel purified. It was ligated to a PCR product encoding *dxs* from *E. coli* with a synthetic RBS. The primers for PCR were MCM13 5'-GATCATGCATTTCGCCCTTAGGAGGTAAAAAACATGAGTTTTGATATTGCCAAATACCCG (SEQ ID NO:18) and MCM14 5'-CATGCTGCAGTTATGCCAGCCAGGCCTTGAT (SEQ ID NO:19); and the template was *E. coli* genomic DNA. The PCR product was digested with *Nsi*I and *Pst*I and gel purified prior to ligation. The resulting transformation reaction was transformed into TOP10 cells and selected on LA with kanamycin 50 µg/ml. Several transformants were isolated and sequenced and the resulting plasmid was called pTrcKudzu-DXS(kan) (Figures 36 and 37).

iv) Construction of pTrcKudzu-yIDI-dxs (kan)

[0527] pTrcKudzu-yIDI(kan) was digested with *Pst*I, treated with SAP, heat killed and gel purified. It was ligated to a PCR product encoding *E. coli dxs* with a synthetic RBS (primers MCM13 5'-GATCATGCATTTCGCCCTTAGGAGGTAAAAAACATGAGTTTTGATATTGCCAA

ATACCCG (SEQ ID NO:18) and MCM14 5'-CATGCTGCAGTTATGCCAGCCAGGCCTTGAT (SEQ ID NO:19); template TOP10 cells) which had been digested with *NsiI* and *PstI* and gel purified. The final plasmid was called pTrcKudzu-yIDI-dxs (kan) (Figures 21 and 22).

v) Construction of pCL PtrcKudzu

[0528] A fragment of DNA containing the promoter, structural gene and terminator from Example 1 above was digested from pTrcKudzu using *SspI* and gel purified. It was ligated to pCL1920 which had been digested with *PvuII*, treated with SAP and heat killed. The resulting ligation mixture was transformed into TOP10 cells and selected in LA containing spectinomycin 50 µg/ml. Several clones were isolated and sequenced and two were selected. pCL PtrcKudzu and pCL PtrcKudzu (A3) have the insert in opposite orientations (Figures 38-41).

vi) Construction of pCL PtrcKudzu yIDI

[0529] The *NsiI-PstI* digested, gel purified, IDI PCR amplicon from (ii) above was ligated into pCL PtrcKudzu which had been digested with *PstI*, treated with SAP, and heat killed. The ligation mixture was transformed into TOP10 cells and selected in LA containing spectinomycin 50 µg/ml. Several clones were isolated and sequenced and the resulting plasmid is called pCL PtrcKudzu yIDI (Figures 42 and 43).

vii) Construction of pCL PtrcKudzu DXS

[0530] The *NsiI-PstI* digested, gel purified, DXS PCR amplicon from (iii) above was ligated into pCL PtrcKudzu (A3) which had been digested with *PstI*, treated with SAP, and heat killed. The ligation mixture was transformed into TOP10 cells and selected in LA containing spectinomycin 50 µg/ml. Several clones were isolated and sequenced and the resulting plasmid is called pCL PtrcKudzu DXS (Figures 44 and 45).

II. Measurement of isoprene in headspace from cultures expressing kudzu isoprene synthase, *idi*, and/or *dxs* at different copy numbers.

[0531] Cultures of *E. coli* BL21(λDE3) previously transformed with plasmids pTrcKudzu(kan) (A), pTrcKudzu-yIDI kan (B), pTrcKudzu-DXS kan (C), pTrcKudzu-yIDI-DXS kan (D) were grown in LB kanamycin 50 µg/mL. Cultures of pCL PtrcKudzu

(E), pCL PtrcKudzu, pCL PtrcKudzu-yIDI (F) and pCL PtrcKudzu-DXS (G) were grown in LB spectinomycin 50 $\mu\text{g/mL}$. Cultures were induced with 400 μM IPTG at time 0 (OD_{600} approximately 0.5) and samples taken for isoprene headspace measurement (see Example 1). Results are shown in Figure 23A-23G.

[0532] Plasmid pTrcKudzu-yIDI-dxs (kan) was introduced into *E. coli* strain BL21 by transformation. The resulting strain BL21/pTrc Kudzu IDI DXS was grown overnight in LB containing kanamycin (50 $\mu\text{g/ml}$) at 20° C and used to inoculate shake flasks of TM3 (13.6 g K_2PO_4 , 13.6 g KH_2PO_4 , 2.0 g $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$), 2.0 g citric acid monohydrate, 0.3 g ferric ammonium citrate, 3.2 g $(\text{NH}_4)_2\text{SO}_4$, 0.2 g yeast extract, 1.0 ml 1000x Modified Trace Metal Solution, adjusted to pH 6.8 and q.s. to H_2O , and filter sterilized) containing 1% glucose. Flasks were incubated at 30° C until an OD_{600} of 0.8 was reached, and then induced with 400 μM IPTG. Samples were taken at various times after induction and the amount of isoprene in the head space was measured as described in Example 1. Results are shown in Figure 23H.

III. Production of isoprene from biomass in *E. coli*/pTrcKudzu yIDI DXS

[0533] The strain BL21 pTrcKudzuIDIDXS was tested for the ability to generate isoprene from three types of biomass; bagasse, corn stover and soft wood pulp with glucose as a control. Hydrolysates of the biomass were prepared by enzymatic hydrolysis (Brown, L and Torget, R., 1996, NREL standard assay method Lap-009 “Enzymatic Saccharification of Lignocellulosic Biomass”) and used at a dilution based upon glucose equivalents. In this example, glucose equivalents were equal to 1% glucose. A single colony from a plate freshly transformed cells of BL21 (DE3) pTrcKudzu yIDI DXS (kan) was used to inoculate 5 ml of LB plus kanamycin (50 $\mu\text{g/ml}$). The culture was incubated overnight at 25° C with shaking. The following day the overnight culture was diluted to an OD_{600} of 0.05 in 25 ml of TM3 + 0.2% YE + 1% feedstock. The feedstock was corn stover, bagasse, or softwood pulp. Glucose was used as a positive control and no glucose was used as a negative control. Cultures were incubated at 30° C with shaking at 180 rpm. The culture was monitored for OD_{600} and when it reached an OD_{600} of ~0.8, cultures were analyzed at 1 and 3 hours for isoprene production as described in Example 1. Cultures are not induced. All cultures containing added feedstock produce isoprene equivalent to those of the glucose positive control. Experiments were done in duplicate and are shown in Figure 46.

IV. Production of isoprene from invert sugar in *E. coli*/pTrcKudzuIDI DXS

[0534] A single colony from a plate freshly transformed cells of BL21 (λ DE3)/pTrcKudzu yIDI DXS (kan) was used to inoculate 5 mL of LB + kanamycin (50 μ g/ml). The culture was incubated overnight at 25° C with shaking. The following day the overnight culture was diluted to an OD₆₀₀ of 0.05 in 25 ml of TM3 + 0.2% YE + 1% feedstock. Feedstock was glucose, inverted glucose or corn stover. The invert sugar feedstock (Danisco Invert Sugar) was prepared by enzymatically treating sucrose syrup. AFEX corn stover was prepared as described below (Part V). The cells were grown at 30° C and the first sample was measured when the cultures reached an OD₆₀₀ ~0.8-1.0 (0 hour). The cultures were analyzed for growth as measured by OD₆₀₀ and for isoprene production as in Example 1 at 0, 1 and 3 hours. Results are shown in Figure 47.

V. Preparation of hydrolysate from AFEX pretreated corn stover

[0535] AFEX pretreated corn stover was obtained from Michigan Biotechnology Institute. The pretreatment conditions were 60% moisture, 1:1 ammonia loading, and 90 °C for 30 minutes, then air dried. The moisture content in the AFEX pretreated corn stover was 21.27%. The contents of glucan and xylan in the AFEX pretreated corn stover were 31.7% and 19.1% (dry basis), respectively. The saccharification process was as follows; 20 g of AFEX pretreated corn stover was added into a 500 ml flask with 5 ml of 1 M sodium citrate buffer pH 4.8, 2.25 ml of Accellerase 1000, 0.1 ml of Grindamyl H121 (Danisco xylanase product from *Aspergillus niger* for bread-making industry), and 72.65 ml of DI water. The flask was put in an orbital shaker and incubated at 50° C for 96 hours. One sample was taken from the shaker and analyzed using HPLC. The hydrolysate contained 38.5 g/l of glucose, 21.8 g/l of xylose, and 10.3 g/l of oligomers of glucose and/or xylose.

VI. The effect of yeast extract on isoprene production in *E. coli* grown in fed-batch culture

[0536] Fermentation was performed at the 14-L scale as previously described with *E. coli* cells containing the pTrcKudzu yIDI DXS plasmid described above. Yeast extract (Bio Springer, Montreal, Quebec, Canada) was fed at an exponential rate. The total amount of yeast extract delivered to the fermentor was varied between 70-830 g during the 40 hour fermentation. Optical density of the fermentation broth was measured at a wavelength of 550 nm. The final optical density within the fermentors was proportional to the amount of

yeast extract added (Figure 48A). The isoprene level in the off-gas from the fermentor was determined as previously described. The isoprene titer increased over the course of the fermentation (Figure 48B). The amount of isoprene produced was linearly proportional to the amount of fed yeast extract (Figure 48C).

VII. Production of isoprene in 500 L fermentation of pTrcKudzu DXS yIDI

[0537] A 500 liter fermentation of *E. coli* cells with a kudzu isoprene synthase, *S. cerevisiae* IDI, and *E. coli* DXS nucleic acids (*E. coli* BL21 (λ DE3) pTrc Kudzu dxs yidi) was used to produce isoprene. The levels of isoprene varied from 50 to 300 μ g/L over a time period of 15 hours. On the basis of the average isoprene concentrations, the average flow through the device and the extent of isoprene breakthrough, the amount of isoprene collected was calculated to be approximately 17 g.

VIII. Production of isoprene in 500 L fermentation of *E. coli* grown in fed-batch culture

Medium Recipe (per liter fermentation medium):

[0538] K_2HPO_4 7.5 g, $MgSO_4 \cdot 7H_2O$ 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, 1000X Modified Trace Metal Solution 1 ml. All of the components were added together and dissolved in diH_2O . This solution was autoclaved. The pH was adjusted to 7.0 with ammonium gas (NH_3) and q.s. to volume. Glucose 10 g, thiamine $\cdot$ HCl 0.1 g, and antibiotic were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0539] Citric Acids $\cdot$ H_2O 40 g, $MnSO_4 \cdot H_2O$ 30 g, NaCl 10 g, $FeSO_4 \cdot 7H_2O$ 1 g, $CoCl_2 \cdot 6H_2O$ 1 g, $ZnSO \cdot 7H_2O$ 1 g, $CuSO_4 \cdot 5H_2O$ 100 mg, H_3BO_3 100 mg, $NaMoO_4 \cdot 2H_2O$ 100 mg. Each component is dissolved one at a time in DI H_2O , pH to 3.0 with HCl/NaOH, then q.s. to volume and filter sterilized with 0.22 micron filter.

[0540] Fermentation was performed in a 500-L bioreactor with *E. coli* cells containing the pTrcKudzu yIDI DXS plasmid. This experiment was carried out to monitor isoprene formation from glucose and yeast extract at the desired fermentation pH 7.0 and temperature 30° C. An inoculum of *E. coli* strain taken from a frozen vial was prepared in soytone-yeast extract-glucose medium. After the inoculum grew to OD 0.15, measured at 550 nm, 20 ml was used to inoculate a bioreactor containing 2.5-L soytone-yeast extract-

glucose medium. The 2.5-L bioreactor was grown at 30° C to OD 1.0 and 2.0-L was transferred to the 500-L bioreactor.

[0541] Yeast extract (Bio Springer, Montreal, Quebec, Canada) and glucose were fed at exponential rates. The total amount of glucose and yeast extract delivered to the bioreactor during the 50 hour fermentation was 181.2 kg and 17.6 kg, respectively. The optical density within the bioreactor over time is shown in Figure 49A. The isoprene level in the off-gas from the bioreactor was determined as previously described. The isoprene titer increased over the course of the fermentation (Figure 49B). The total amount of isoprene produced during the 50 hour fermentation was 55.1 g and the time course of production is shown in Figure 49C.

Example 8: Production of isoprene in *E. coli* expressing kudzu isoprene synthase and recombinant mevalonic acid pathway genes

I. Cloning the lower MVA pathway

[0542] The strategy for cloning the lower mevalonic pathway was as follows. Four genes of the mevalonic acid biosynthesis pathway; mevalonate kinase (MVK), phosphomevalonate kinase (PMK), diphosphomevalonate decarboxylase (MVD) and isopentenyl diphosphate isomerase genes were amplified by PCR from *S. cerevisiae* chromosomal DNA and cloned individually into the pCR BluntII TOPO plasmid (Invitrogen). In some cases, the *idi* gene was amplified from *E. coli* chromosomal DNA. The primers were designed such that an *E. coli* consensus RBS (AGGAGGT (SEQ ID NO:80) or AAGGAGG (SEQ ID NO:81)) was inserted at the 5' end, 8 bp upstream of the start codon and a *Pst*I site was added at the 3' end. The genes were then cloned one by one into the pTrcHis2B vector until the entire pathway was assembled.

[0543] Chromosomal DNA from *S. cerevisiae* S288C was obtained from ATCC (ATCC 204508D). The MVK gene was amplified from the chromosome of *S. cerevisiae* using primers MVKF (5'-AGGAGGTAAAAAACATGTCATTACCGTTCTTA ACTTCTGC, SEQ ID NO:21) and MVK-PstI-R (5'-ATGGCTGCAGGCCTATCGCAAATTAGCTTATGAAGTCCATGGTAAATTCGTG, SEQ ID NO:22) using PfuTurbo as per manufacturer's instructions. The correct sized PCR product (1370 bp) was identified by electrophoresis through a 1.2% E-gel (Invitrogen) and cloned into pZeroBLUNT TOPO. The resulting plasmid was designated pMVK1. The

plasmid pMVK1 was digested with *SacI* and *TaqI* restriction endonucleases and the fragment was gel purified and ligated into pTrcHis2B digested with *SacI* and *BstBI*. The resulting plasmid was named pTrcMVK1.

[0544] The second gene in the mevalonic acid biosynthesis pathway, PMK, was amplified by PCR using primers: PstI-PMK1 R (5'-GAATTCGCCCTTCTGCAGCTACC, SEQ ID NO:23) and BsiHKA I-PMK1 F (5'-CGACTGGTGCACCCTTAAGGAGGAAAAAACATGTCAG, SEQ ID NO:24). The PCR reaction was performed using Pfu Turbo polymerase (Stratagene) as per manufacturer's instructions. The correct sized product (1387 bp) was digested with *PstI* and *BsiHKA I* and ligated into pTrcMVK1 digested with *PstI*. The resulting plasmid was named pTrcKK. The MVD and the *idi* genes were cloned in the same manner. PCR was carried out using the primer pairs PstI-MVD 1 R (5'-GTGCTGGAATTCGCCCTTCTGCAGC, SEQ ID NO:25) and NsiI-MVD 1 F (5'-GTAGATGCATGCAGAATTCGCCCTTAAGGAGG, SEQ ID NO:26) to amplify the MVD gene and PstI-YIDI 1 R (5'-CCTTCTGCAGGACGCGTTGTTATAGC, SEQ ID NO:27) and NsiI-YIDI 1 F (5'-CATCAATGCATCGCCCTTAGGAGGTAAAAAAAATGAC, SEQ ID NO:28) to amplify the yIDI gene. In some cases the IPP isomerase gene, *idi* from *E. coli* was used. To amplify *idi* from *E. coli* chromosomal DNA, the following primer set was used: PstI-CIDI 1 R (5'-GTGTGATGGATATCTGCAGAATTCG, SEQ ID NO:29) and NsiI-CIDI 1 F (5'-CATCAATGCATCGCCCTTAGGAGGTAAAAAACATG, SEQ ID NO:30). Template DNA was chromosomal DNA isolated by standard methods from *E. coli* FM5 (WO 96/35796 and WO 2004/033646, which are each hereby incorporated by reference in their entireties, particularly with respect to isolation of nucleic acids). The final plasmids were named pKKDIy for the construct encoding the yeast *idi* gene or pKKDIc for the construct encoding the *E. coli* *idi* gene. The plasmids were transformed into *E. coli* hosts BL21 for subsequent analysis. In some cases the isoprene synthase from kudzu was cloned into pKKDIy yielding plasmid pKKDIyIS.

[0545] The lower MVA pathway was also cloned into pTrc containing a kanamycin antibiotic resistance marker. The plasmid pTrcKKDIy was digested with restriction endonucleases *ApaI* and *PstI*, the 5930 bp fragment was separated on a 1.2% agarose E-gel and purified using the Qiagen Gel Purification kit according to the manufacturer's

instructions. The plasmid pTrcKudzuKan, described in Example 7, was digested with restriction endonucleases *ApaI* and *PstI*, and the 3338 bp fragment containing the vector was purified from a 1.2% E-gel using the Qiagen Gel Purification kit. The 3338 bp vector fragment and the 5930 bp lower MVA pathway fragment were ligated using the Roche Quick Ligation kit. The ligation mix was transformed into *E. coli* TOP10 cells and transformants were grown at 37° C overnight with selection on LA containing kanamycin (50 µg/ml). The transformants were verified by restriction enzyme digestion and one was frozen as a stock. The plasmid was designated pTrcKanKKDIy.

II. Cloning a kudzu isoprene synthase gene into pTrcKanKKDIy

[0546] The kudzu isoprene synthase gene was amplified by PCR from pTrcKudzu, described in Example 1, using primers MCM50 5'-

GATCATGCATTTCGCCCTTAGGAGGTAAAAAACATGTGTGCGACCTCTTCTCA
ATTACT (SEQ ID NO:31) and MCM53 5'-

CGGTCGACGGATCCCTGCAGTTAGACATACATCAGCTG (SEQ ID NO:32). The resulting PCR fragment was cloned into pCR2.1 and transformed into *E. coli* TOP10. This fragment contains the coding sequence for kudzu isoprene synthase and an upstream region containing a RBS from *E. coli*. Transformants were incubated overnight at 37° C with selection on LA containing carbenicillin (50 µg/ml). The correct insertion of the fragment was verified by sequencing and this strain was designated MCM93.

[0547] The plasmid from strain MCM93 was digested with restriction endonucleases *NsiI* and *PstI* to liberate a 1724 bp insert containing the RBS and kudzu isoprene synthase. The 1724 bp fragment was separated on a 1.2% agarose E-gel and purified using the Qiagen Gel Purification kit according to the manufacturer's instructions. Plasmid pTrcKanKKDIy was digested with the restriction endonuclease *PstI*, treated with SAP for 30 minutes at 37° C and purified using the Qiagen PCR cleanup kit. The plasmid and kudzu isoprene synthase encoding DNA fragment were ligated using the Roche Quick Ligation kit. The ligation mix was transformed into *E. coli* TOP10 cells and transformants were grown overnight at 37° C with selection on LA containing Kanamycin at 50 µg/ml. The correct transformant was verified by restriction digestion and the plasmid was designated pTrcKKDyIkISKan (Figures 24 and 25). This plasmid was transformed into BL21(λDE3) cells (Invitrogen).

III. Isoprene production from mevalonate in *E. coli* expressing the recombinant lower mevalonate pathway and isoprene synthase from kudzu.

[0548] Strain BL21/pTrcKKDyIkISKan was cultured in MOPS medium (Neidhardt *et al.*, (1974) *J. Bacteriology* 119:736-747) adjusted to pH 7.1 and supplemented with 0.5% glucose and 0.5% mevalonic acid. A control culture was also set up using identical conditions but without the addition of 0.5% mevalonic acid. The culture was started from an overnight seed culture with a 1% inoculum and induced with 500 μ M IPTG when the culture had reached an OD₆₀₀ of 0.3 to 0.5. The cultures were grown at 30° C with shaking at 250 rpm. The production of isoprene was analyzed 3 hours after induction by using the head space assay described in Example 1. Maximum production of isoprene was 6.67×10^{-4} mol/L_{broth}/OD₆₀₀/hr where L_{broth} is the volume of broth and includes both the volume of the cell medium and the volume of the cells. The control culture not supplemented with mevalonic acid did not produce measurable isoprene.

IV. Cloning the upper MVA pathway

[0549] The upper mevalonate biosynthetic pathway, comprising two genes encoding three enzymatic activities, was cloned from *Enterococcus faecalis*. The *mvaE* gene encodes a protein with the enzymatic activities of both acetyl-CoA acetyltransferase and 3-hydroxy-3-methylglutaryl-CoA (HMG-CoA) reductase, the first and third proteins in the pathway, and the *mvaS* gene encodes second enzyme in the pathway, HMG-CoA synthase. The *mvaE* gene was amplified from *E. faecalis* genomic DNA (ATCC 700802D-5) with an *E. coli* ribosome binding site and a spacer in front using the following primers:

CF 07-60 (+) Start of *mvaE* w/ RBS + ATG start codon *SacI*

5' - GAGACATGAGCTCAGGAGGTAAAAAACATGAAAACAGTAGTTATTATTG
(SEQ ID NO:34)

CF 07-62 (-) Fuse *mvaE* to *mvaS* with RBS in between

5' - TTTATCAATCCCAATTGTCATGTTTTTTTACCTCCTTTATTGTTTTCTTAAATC
(SEQ ID NO:35)

[0550] The *mvaS* gene was amplified from *E. faecalis* genomic DNA (ATCC 700802D-5) with a RBS and spacer from *E. coli* in front using the following primers:

CF 07-61 (+) Fuse *mvaE* to *mvaS* with RBS in between

5' -

GATTTAAGAAAACAATAAAGGAGGTAAAAAACATGACAATTGGGATTGATAAA
(SEQ ID NO:36)

CF 07-102 (-) End of *mvaS* gene *Bgl*III

5' -GACATGACATAGATCTTTAGTTTCGATAAGAACGAACGGT (SEQ ID NO:37)

[0551] The PCR fragments were fused together with PCR using the following primers:

CF 07-60 (+) Start of *mvaE* w/ RBS + ATG start codon *Sac*I

5' -GAGACATGAGCTCAGGAGGTAAAAAACATGAAAACAGTAGTTATTATTG
(SEQ ID NO:34)

CF 07-102 (-) End of *mvaS* gene *Bgl*III

5'-GACATGACATAGATCTTTAGTTTCGATAAGAACGAACGGT (SEQ ID NO:37)

[0552] The fusion PCR fragment was purified using a Qiagen kit and digested with the restriction enzymes *Sac*I and *Bgl*III. This digested DNA fragment was gel purified using a Qiagen kit and ligated into the commercially available vector pTrcHis2A, which had been digested with *Sac*I and *Bgl*III and gel purified.

[0553] The ligation mix was transformed into *E. coli* Top 10 cells and colonies were selected on LA+50 µg/ml carbenicillin plates. A total of six colonies were chosen and grown overnight in LB+50 µg/ml carbenicillin and plasmids were isolated using a Qiagen kit. The plasmids were digested with *Sac*I and *Bgl*III to check for inserts and one correct plasmid was sequenced with the following primers:

CF 07-58 (+) Start of *mvaE* gene

5' – ATGAAAACAGTAGTTATTATTGATGC (SEQ ID NO:38)

CF 07-59 (-) End of *mvaE* gene

5' – ATGTTATTGTTTTCTTAAATCATTTAAAATAGC (SEQ ID NO:39)

CF 07-82 (+) Start of *mvaS* gene

5' – ATGACAATTGGGATTGATAAAATTAG (SEQ ID NO:40)

CF 07-83 (-) End of *mvaS* gene

5' – TTAGTTTTCGATAAGAACGAACGGT (SEQ ID NO:41)

CF 07-86 (+) Sequence in *mvaE*

5' – GAAATAGCCCCATTAGAAGTATC (SEQ ID NO:42)

CF 07-87 (+) Sequence in *mvaE*

5' – TTGCCAATCATATGATTGAAAATC (SEQ ID NO:43)

CF 07-88 (+) Sequence in *mvaE*

5' – GCTATGCTTCATTAGATCCTTATCG (SEQ ID NO:44)

CF 07-89 (+) Sequence *mvaS*

5' – GAAACCTACATCCAATCTTTTGCCC (SEQ ID NO:45)

[0554] The plasmid called pTrcHis2AUpperPathway#1 was correct by sequencing and was transformed into the commercially available *E. coli* strain BL21. Selection was done on LA+ 50 µg/ml carbenicillin. Two transformants were chosen and grown in LB+ 50 µg/ml carbenicillin until they reached an OD₆₀₀ of 1.5. Both strains were frozen in a vial at -80° C in the presence of glycerol. Strains were designated CF 449 for pTrcHis2AUpperPathway#1 in BL21, isolate #1 and CF 450 for pTrcHis2AUpperPathway#1 in BL21, isolate #2. Both clones were found to behave identically when analyzed.

V. Cloning of UpperMVA Pathway into pCL1920

[0555] The plasmid pTrcHis2AUpperPathway was digested with the restriction endonuclease *SspI* to release a fragment containing pTrc-*mvaE-mvaS*-(His tag)-terminator. In this fragment, the his-tag was not translated. This blunt ended 4.5 kbp fragment was purified from a 1.2% E-gel using the Qiagen Gel Purification kit. A dephosphorylated, blunt ended 4.2 kbp fragment from pCL1920 was prepared by digesting the vector with the restriction endonuclease *PvuII*, treating with SAP and gel purifying from a 1.2% E-gel using the

Qiagen Gel Purification kit. The two fragments were ligated using the Roche Quick Ligation Kit and transformed into TOP10 chemically competent cells. Transformants were selected on LA containing spectinomycin (50 µg/ml). A correct colony was identified by screening for the presence of the insert by PCR. The plasmid was designated pCLPTrcUpperPathway (Figures 26 and 27A-27D).

VI. Strains expressing the combined Upper and Lower Mevalonic Acid Pathways

[0556] To obtain a strain with a complete mevalonic acid pathway plus kudzu isoprene synthase, plasmids pTrcKKDyIkISkan and pCLPTrcUpperPathway were both transformed into BL21(λDE3) competent cells (Invitrogen) and transformants were selected on LA containing kanamycin (50 µg/ml) and Spectinomycin (50 µg/ml). The transformants were checked by plasmid prep to ensure that both plasmids were retained in the host. The strain was designated MCM127.

VII. Production of mevalonic acid from glucose in *E. coli*/pUpperpathway

[0557] Single colonies of the BL21/pTrcHis2A-*mvaE/mvaS* or FM5/pTrcHis2A-*mvaE/mvaS* are inoculated into LB + carbenicillin (100 µg/ml) and are grown overnight at 37° C with shaking at 200 rpm. These cultures were diluted into 50 ml medium in 250 ml baffled flasks to an OD₆₀₀ of 0.1. The medium was TM3 + 1 or 2% glucose + carbenicillin (100 ug/ml) or TM3 + 1% glucose + hydrolyzed soy oil + carbenicillin (100 ug/ml) or TM3 + biomass (prepared bagasse, corn stover or switchgrass). Cultures were grown at 30° C with shaking at 200 rpm for approximately 2-3 hours until an OD₆₀₀ of 0.4 was reached. At this point the expression from the *mvaE mvaS* construct was induced by the addition of IPTG (400 µM). Cultures were incubated for a further 20 or 40 hours with samples taken at 2 hour intervals to 6 hour post induction and then at 24, 36 and 48 hours as needed. Sampling was done by removing 1 ml of culture, measuring the OD₆₀₀, pelleting the cells in a microfuge, removing the supernatant and analyzing it for mevalonic acid.

[0558] A 14 liter fermentation of *E. coli* cells with nucleic acids encoding *Enterococcus faecalis* AA-CoA thiolase, HMG-CoA synthase, and HMG-CoA reductase polypeptides produced 22 grams of mevalonic acid with TM3 medium and 2% glucose as the cell medium. A shake flask of these cells produced 2-4 grams of mevalonic acid per liter with

LB medium and 1% glucose as the cell culture medium. The production of mevalonic acid in these strains indicated that the MVA pathway was functional in *E. coli*.

VIII. Production of isoprene from *E. coli* BL21 containing the upper and lower MVA pathway plus kudzu isoprene synthase.

[0559] The following strains were created by transforming in various combinations of plasmids containing the upper and lower MVA pathway and the kudzu isoprene synthase gene as described above and the plasmids containing the *idi*, *dxs*, and *dxr* and isoprene synthase genes described in Example 7. The host cells used were chemically competent BL21(λ DE3) and the transformations were done by standard methods. Transformants were selected on L agar containing kanamycin (50 μ g/ml) or kanamycin plus spectinomycin (both at a concentration of 50 μ g/ml). Plates were grown at 37° C. The resulting strains were designated as follows:

Grown on Kanamycin plus Spectinomycin (50 μ g/ml each)

MCM127 - pCL Upper MVA + pTrcKKDyIkIS (kan) in BL21(λ DE3)

MCM131 - pCL1920 + pTrcKKDyIkIS (kan) in BL21(λ DE3)

MCM125 - pCL Upper MVA + pTrcHis2B (kan) in BL21(λ DE3)

Grown on Kanamycin (50 μ g/ml)

MCM64 - pTrcKudzu yIDI DXS (kan) in BL21(λ DE3)

MCM50 - pTrcKudzu (kan) in BL21(λ DE3)

MCM123 - pTrcKudzu yIDI DXS DXR (kan) in BL21(λ DE3)

[0560] The above strains were streaked from freezer stocks to LA + appropriate antibiotic and grown overnight at 37° C. A single colony from each plate was used to inoculate shake flasks (25 ml LB + the appropriate antibiotic). The flasks were incubated at 22° C overnight with shaking at 200 rpm. The next morning the flasks were transferred to a 37° C incubator and grown for a further 4.5 hours with shaking at 200 rpm. The 25 ml cultures were centrifuged to pellet the cells and the cells were resuspended in 5 ml LB + the appropriate antibiotic. The cultures were then diluted into 25 ml LB+1% glucose + the appropriate antibiotic to an OD₆₀₀ of 0.1. Two flasks for each strain were set up, one set for induction with IPTG (800 μ M) the second set was not induced. The cultures were incubated at 37° C with shaking at 250 rpm. One set of the cultures were induced after

1.50 hours (immediately following sampling time point 1). At each sampling time point, the OD₆₀₀ was measured and the amount of isoprene determined as described in Example 1. Results are presented in Table 3. The amount of isoprene made is presented as the amount at the peak production for the particular strain.

Table 3. Production of isoprene in *E. coli* strains

Strain	Isoprene (µg/liter/OD/hr)
MCM50	23.8
MCM64	289
MCM125	ND
MCM131	Trace
MCM127	874

ND: not detected

Trace: peak present but not integrable.

IX. Analysis of mevalonic acid

[0561] Mevalonolactone (1.0 g, 7.7 mmol) (CAS# 503-48-0) was supplied from Sigma-Aldrich (WI, USA) as a syrup that was dissolved in water (7.7 mL) and was treated with potassium hydroxide (7.7 mmol) in order to generate the potassium salt of mevalonic acid. The conversion to mevalonic acid was confirmed by ¹H NMR analysis. Samples for HPLC analysis were prepared by centrifugation at 14,000 rpm for 5 minutes to remove cells, followed by the addition of a 300 µl aliquot of supernatant to 900 µl of H₂O. Perchloric acid (36 µl of a 70% solution) was then added followed by mixing and cooling on ice for 5 minutes. The samples were then centrifuged again (14,000 rpm for 5 min) and the supernatant transferred to HPLC. Mevalonic acid standards (20, 10, 5, 1 and 0.5 g/L) were prepared in the same fashion. Analysis of mevalonic acid (20 µL injection volume) was performed by HPLC using a BioRad Aminex 87-H+ column (300 mm by 7.0 mm) eluted with 5 mM sulfuric acid at 0.6 mL/min with refractive index (RI) detection. Under these conditions mevalonic acid eluted as the lactone form at 18.5 minutes.

X. Production of isoprene from *E. coli* BL21 containing the upper MVA pathway plus kudzu isoprene synthase

[0562] A 15-L scale fermentation of *E. coli* expressing mevalonic acid pathway polypeptides and Kudzu isoprene synthase was used to produce isoprene from cells in fed-batch culture.

This experiment demonstrates that growing cells under glucose limiting conditions resulted in the production of 2.2 g/L of isoprene.

Medium Recipe (per liter fermentation medium):

[0563] The medium was generated using the following components per liter fermentation medium: K_2HPO_4 7.5 g, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, and 1000X modified trace metal solution 1 ml. All of the components were added together and dissolved in dH_2O . This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to volume. Glucose 10 g, thiamine $\cdot$ HCl 0.1 g, and antibiotics were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0564] The 1000X modified trace metal solution was generated using the following components: citric acids $\cdot$ H_2O 40 g, $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ 30 g, NaCl 10 g, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ 1 g, $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ 1 g, $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ 1 g, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ 100 mg, H_3BO_3 100 mg, and $\text{NaMoO}_4 \cdot 2\text{H}_2\text{O}$ 100 mg. Each component was dissolved one at a time in dH_2O , pH to 3.0 with HCl/NaOH, then q.s. to volume, and filter sterilized with a 0.22 micron filter.

[0565] Fermentation was performed in a 15-L bioreactor with BL21 (DE3) *E. coli* cells containing the pCL PtrcUpperPathway (Figure 26) and pTrcKKDyIkIS plasmids. This experiment was carried out to monitor isoprene formation from glucose at the desired fermentation pH 7.0 and temperature 30°C. An inoculum of *E. coli* strain taken from a frozen vial was streaked onto an LB broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into soytone-yeast extract-glucose medium. After the inoculum grew to OD 1.0 when measured at 550 nm, 500 mL was used to inoculate a 5-L bioreactor.

[0566] Glucose was fed at an exponential rate until cells reached the stationary phase. After this time the glucose feed was decreased to meet metabolic demands. The total amount of glucose delivered to the bioreactor during the 54 hour fermentation was 3.7 kg. Induction was achieved by adding isopropyl-beta-D-1-thiogalactopyranoside (IPTG). The IPTG concentration was brought to 25 μM when the optical density at 550 nm (OD_{550}) reached a value of 10. The IPTG concentration was raised to 50 μM when OD_{550} reached 190. IPTG

concentration was raised to 100 μ M at 38 hours of fermentation. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 54. The isoprene level in the off gas from the bioreactor was determined as described herein. The isoprene titer increased over the course of the fermentation to a final value of 2.2 g/L (Fig. 55). The total amount of isoprene produced during the 54 hour fermentation was 15.9 g, and the time course of production is shown in Fig. 56.

[0567] XI. Isoprene fermentation from *E. coli* expressing genes from the mevalonic acid pathway and grown in fed-batch culture at the 15-L scale

[0568] A 15-L scale fermentation of *E. coli* expressing mevalonic acid pathway polypeptides and Kudzu isoprene synthase was used to produce isoprene from cells in fed-batch culture. This experiment demonstrates that growing cells under glucose limiting conditions resulted in the production of 3.0 g/L of isoprene.

Medium Recipe (per liter fermentation medium):

[0569] The medium was generated using the following components per liter fermentation medium: K₂HPO₄ 7.5 g, MgSO₄ * 7H₂O 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, and 1000X Modified Trace Metal Solution 1 ml. All of the components were added together and dissolved in diH₂O. This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to volume. Glucose 10 g, thiamine * HCl 0.1 g, and antibiotics were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0570] The 1000X modified trace metal solution was generated using the following components: citric acids * H₂O 40 g, MnSO₄ * H₂O 30 g, NaCl 10 g, FeSO₄ * 7H₂O 1 g, CoCl₂ * 6H₂O 1 g, ZnSO * 7H₂O 1 g, CuSO₄ * 5H₂O 100 mg, H₃BO₃ 100 mg, and NaMoO₄ * 2H₂O 100 mg. Each component was dissolved one at a time in diH₂O, pH to 3.0 with HCl/NaOH, then q.s. to volume, and filter sterilized with a 0.22 micron filter.

[0571] Fermentation was performed in a 15-L bioreactor with BL21 (DE3) *E. coli* cells containing the pCL PtrcUpperMVA and pTrc KKDYIkIS plasmids. This experiment was carried out to monitor isoprene formation from glucose at the desired fermentation pH 7.0

and temperature 30°C. An inoculum of *E. coli* strain taken from a frozen vial was streaked onto an LB broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into tryptone-yeast extract medium. After the inoculum grew to OD 1.0, measured at 550 nm, 500 mL was used to inoculate a 5-L bioreactor.

[0572] Glucose was fed at an exponential rate until cells reached the stationary phase. After this time, the glucose feed was decreased to meet metabolic demands. The total amount of glucose delivered to the bioreactor during the 59 hour fermentation was 2.2 kg. Induction was achieved by adding IPTG. The IPTG concentration was brought to 25 μ M when the optical density at 550 nm (OD₅₅₀) reached a value of 10. The IPTG concentration was raised to 50 μ M when OD₅₅₀ reached 190. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 93. The isoprene level in the off gas from the bioreactor was determined as described herein. The isoprene titer increased over the course of the fermentation to a final value of 3.0 g/L (Fig. 94). The total amount of isoprene produced during the 59 hour fermentation was 22.8 g, and the time course of production is shown in FIG 95. The molar yield of utilized carbon that went into producing isoprene during fermentation was 2.2%. The weight percent yield of isoprene from glucose was 1.0%.

[0573] XII. Isoprene fermentation from *E. coli* expressing genes from the mevalonic acid pathway and grown in fed-batch culture at the 15-L scale

[0574] A 15-L scale fermentation of *E. coli* expressing mevalonic acid pathway polypeptides, *Pueraria lobata* isoprene synthase, and Kudzu isoprene synthase was used to produce isoprene from cells in fed-batch culture. This experiment demonstrates that growing cells under glucose limiting conditions resulted in the production of 3.3 g/L of isoprene.

[0575] i) Construction of pCLPtrcUpperPathwayHGS2

[0576] The gene encoding isoprene synthase from *Pueraria lobata* was PCR-amplified using primers NsiI-RBS-HGS F (CTTGATGCATCCTGCATTCGCCCTTAGGAGG, SEQ ID NO:88) and pTrcR (CCAGGCAAATTCTGTTTTATCAG, SEQ ID NO:89), and pTrcKKDyIkIS as a template. The PCR product thus obtained was restriction-digested with NsiI and PstI and gel-purified. The plasmid pCL PtrcUpperPathway was restriction-digested with PstI and dephosphorylated using rAPid alkaline phosphatase (Roche) according to manufacturer's instructions.

[0577] These DNA fragments were ligated together and the ligation reaction was transformed into *E. coli* Top10 chemically competent cells (Invitrogen), plated on L agar containing spectinomycin (50 ug/ml) and incubated overnight at 37°C. Plasmid DNA was prepared from 6 clones using the Qiaquick Spin Mini-prep kit. The plasmid DNA was digested with restriction enzymes *EcoRV* and *MluI* to identify a clone in which the insert had the right orientation (*i.e.*, the gene oriented in the same way as the pTrc promoter).

[0578] The resulting correct plasmid was designated pCLPtrcUpperPathwayHGS2. This plasmid was assayed using the headspace assay described herein and found to produce isoprene in *E. coli* Top10, thus validating the functionality of the gene. The plasmid was transformed into BL21(LDE3) containing pTrcKKDyIkIS to yield the strain BL21/pCLPtrcUpperPathwayHGS2-pTrcKKDyIkIS. This strain has an extra copy of the isoprene synthase compared to the BL21/pCL PtrcUpperMVA and pTrc KKDyIkIS strain (Example 8, part XI). This strain also had increased expression and activity of HMGS compared to the BL21/pCL PtrcUpperMVA and pTrc KKDyIkIS strain used in Example 8, part XI.

ii) Isoprene fermentation from *E. coli* expressing pCLPtrcUpperPathwayHGS2-pTrcKKDyIkIS and grown in fed-batch culture at the 15-L scale

[0579] Medium Recipe (per liter fermentation medium):

[0580] The medium was generated using the following components per liter fermentation medium: K₂HPO₄ 7.5 g, MgSO₄ * 7H₂O 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, and 1000X modified trace metal solution 1 ml. All of the components were added together and dissolved in diH₂O. This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to volume. Glucose 10 g, thiamine * HCl 0.1 g, and antibiotics were added after sterilization and pH adjustment.

[0581] 1000X Modified Trace Metal Solution:

[0582] The 1000X modified trace metal solution was generated using the following components: citric acids * H₂O 40 g, MnSO₄ * H₂O 30 g, NaCl 10 g, FeSO₄ * 7H₂O 1 g, CoCl₂ * 6H₂O 1 g, ZnSO * 7H₂O 1 g, CuSO₄ * 5H₂O 100 mg, H₃BO₃ 100 mg, and

$\text{NaMoO}_4 \cdot 2\text{H}_2\text{O}$ 100 mg. Each component is dissolved one at a time in H_2O , pH to 3.0 with HCl/NaOH , then q.s. to volume and filter sterilized with 0.22 micron filter.

[0583] Fermentation was performed in a 15-L bioreactor with BL21 (DE3) *E. coli* cells containing the pCLPtrcUpperPathwayHGS2 and pTrc KKDyIkIS plasmids. This experiment was carried out to monitor isoprene formation from glucose at the desired fermentation pH 7.0 and temperature 30°C. An inoculum of *E. coli* strain taken from a frozen vial was streaked onto an LB broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into tryptone-yeast extract medium. After the inoculum grew to OD 1.0 measured at 550 nm, 500 mL was used to inoculate a 5-L bioreactor.

[0584] Glucose was fed at an exponential rate until cells reached the stationary phase. After this time the glucose feed was decreased to meet metabolic demands. The total amount of glucose delivered to the bioreactor during the 58 hour fermentation was 2.1 kg. Induction was achieved by adding IPTG. The IPTG concentration was brought to 25 μM when the optical density at 550 nm (OD_{550}) reached a value of 9. The IPTG concentration was raised to 50 μM when OD_{550} reached 170. The OD_{550} profile within the bioreactor over time is shown in Fig. 104. The isoprene level in the off gas from the bioreactor was determined as described herein. The isoprene titer increased over the course of the fermentation to a final value of 3.3 g/L (Fig. 105). The total amount of isoprene produced during the 58 hour fermentation was 24.5 g and the time course of production is shown in Fig. 106. The molar yield of utilized carbon that went into producing isoprene during fermentation was 2.5%. The weight percent yield of isoprene from glucose was 1.2%. Analysis showed that the activity of the isoprene synthase was increased by approximately 3-4 times that compared to BL21 expressing CL PtrcUpperMVA and pTrc KKDyIkIS plasmids (data not shown).

XIII. Chromosomal Integration of the Lower Mevalonate Pathway in *E. coli*.

[0585] A synthetic operon containing mevalonate kinase, mevalonate phosphate kinase, mevalonate pyrophosphate decarboxylase, and the IPP isomerase was integrated into the chromosome of *E. coli*. If desired, expression may be altered by integrating different promoters 5' of the operon.

[0586] Table 9 lists primers used for this experiment.

i) Target vector construction

[0587] The attTn7 site was selected for integration. Regions of homology upstream (attTn7 up) (primers MCM78 and MCM79) and downstream (attTn7 down) (primers MCM88 and MCM89) were amplified by PCR from MG1655 cells. A 50 uL reaction with 1uL 10uM primers, 3uL ddH₂O, 45uL Invitrogen Platinum PCR Supermix High Fidelity, and a scraped colony of MG1655 was denatured for 2:00 at 94°C, cycled 25 times (2:00 at 94°C, 0:30 at 50°C, and 1:00 at 68°C), extended for 7:00 at 72°C, and cooled to 4°C. This resulting DNA was cloned into pCR2.1 (Invitrogen) according to the manufacturer's instructions, resulting in plasmids MCM278 (attTn7 up) and MCM252 (attTn7 down). The 832bp *ApaI*-*PvuI* fragment digested and gel purified from MCM252 was cloned into *ApaI*-*PvuI* digested and gel purified plasmid pR6K, creating plasmid MCM276. The 825bp *PstI*-*NotI* fragment digested and gel purified from MCM278 was cloned into *PstI*-*NotI* digested and gel purified MCM276, creating plasmid MCM281.

[0588] ii) Cloning of lower pathway and promoter

[0589] MVK-PMK-MVD-IDI genes were amplified from pTrcKKDyIkIS with primers MCM104 and MCM105 using Roche Expand Long PCR System according to the manufacturer's instructions. This product was digested with *NotI* and *ApaI* and cloned into MCM281 which had been digested with *NotI* and *ApaI* and gel purified. Primers MCM120

and MCM127 were used to amplify CMR cassette from the GeneBridges FRT-gb2-Cm-FRT template DNA using Stratagene Pfu Ultra II. A PCR program of denaturing at 95°C for 4:00, 5 cycles of 95°C for 0:20, 55°C for 0:20, 72°C for 2:00, 25 cycles of 95°C for 0:20, 58°C for 0:20, 72°C for 2:00, 72°C for 10:00, and then cooling to 4°C was used with four 50uL PCR reactions containing 1uL ~10ng/uL template, 1uL each primer, 1.25 uL 10mM dNTPs, 5uL 10x buffer, 1uL enzyme, and 39.75uL ddH₂O. Reactions were pooled, purified on a Qiagen PCR cleanup column, and used to electroporate water-washed Pir1 cells containing plasmid MCM296. Electroporation was carried out in 2mM cuvettes at 2.5V and 200 ohms. Electroporation reactions were recovered in LB for 3hr at 30°C. Transformant MCM330 was selected on LA with CMP5, Kan50 (Figures 107 and 108A-108C).

[0590] iii) Integration into *E. coli* chromosome

[0591] Miniprep DNA (Qiaquick Spin kit) from MCM330 was digested with *Sna*BI and used to electroporate BL21(DE3) (Novagen) or MG1655 containing GeneBridges plasmid pRedET Carb. Cells were grown at 30°C to ~OD1 then induced with 0.4% L-arabinose at 37°C for 1.5 hours. These cells were washed three times in 4°C ddH₂O before electroporation with 2uL of DNA. Integrants were selected on L agar with containing chloramphenicol (5 ug/ml) and subsequently confirmed to not grow on L agar + Kanamycin (50 ug/ml). BL21 integrant MCM331 and MG1655 integrant MCM333 were frozen.

[0592] iv) Construction of pET24D-Kudzu encoding Kudzu isoprene synthase

[0593] The kudzu isoprene synthase gene was subcloned into the pET24d vector (Novagen) from the pCR2.1 vector (Invitrogen). In particular, the kudzu isoprene synthase gene was amplified from the pTrcKudzu template DNA using primers MCM50 5'-GATCATGCAT TCGCCCTTAG GAGGTAAAAA AACATGTGTG CGACCTCTTC TCAATTTACT (SEQ ID NO:99) and MCM53 5'-CGGTCGACGG ATCCCTGCAG TTAGACATAC ATCAGCTG (SEQ ID NO:100). PCR reactions were carried out using Taq DNA Polymerase (Invitrogen), and the resulting PCR product was cloned into pCR2.1-TOPO TA cloning vector (Invitrogen), and transformed into *E. coli* Top10 chemically competent cells (Invitrogen). Transformants were plated on L agar containing carbenicillin (50 µg/ml) and incubated overnight at 37°C. Five ml Luria Broth cultures containing

carbenicillin 50 µg/ml were inoculated with single transformants and grown overnight at 37°C. Five colonies were screened for the correct insert by sequencing of plasmid DNA isolated from 1 ml of liquid culture (Luria Broth) and purified using the QIAprep Spin Mini-prep Kit (Qiagen). The resulting plasmid, designated MCM93, contains the kudzu isoprene synthase coding sequence in a pCR2.1 backbone.

[0594] The kudzu coding sequence was removed by restriction endonuclease digestion with *PciI* and *BamHI* (Roche) and gel purified using the QIAquick Gel Extraction kit (Qiagen). The pET24d vector DNA was digested with *NcoI* and *BamHI* (Roche), treated with shrimp alkaline phosphatase (Roche), and purified using the QIAprep Spin Mini-prep Kit (Qiagen). The kudzu isoprene synthase fragment was ligated to the *NcoI/BamHI* digested pET24d using the Rapid DNA Ligation Kit (Roche) at a 5:1 fragment to vector ratio in a total volume of 20 µl. A portion of the ligation mixture (5 µl) was transformed into *E. coli* Top 10 chemically competent cells and plated on L agar containing kanamycin (50 µg/ml). The correct transformant was confirmed by sequencing and transformed into chemically competent BL21(λDE3)pLysS cells (Novagen). A single colony was selected after overnight growth at 37°C on L agar containing kanamycin (50 µg/ml). A map of the resulting plasmid designated as pET24D-Kudzu is shown in Figure 109. The sequence of pET24D-Kudzu (SEQ ID NO:101) is shown in Figures 110A and 110B. Isoprene synthase activity was confirmed using a headspace assay.

[0595] v) Production strains

[0596] Strains MCM331 and MCM333 were cotransformed with plasmids pCLP_{trc}upperpathway and either pTrcKudzu or pETKudzu, resulting in the strains shown in Table 10.

Table 10. Production Strains

Background	Integrated Lower	Upper MVA plasmid	Isoprene synthase plasmid	Production Stain
BL21(DE3)	MCM331	pCLP _{trc} Upper Pathway	pTrcKudzu	MCM343
BL21(DE3)	MCM331	pCLP _{trc} Upper Pathway	pET24D-Kudzu	MCM335
MG1655	MCM333	pCLP _{trc} Upper Pathway	pTrcKudzu	MCM345

vi) Isoprene fermentation from *E. coli* expressing genes from the mevalonic acid pathway and grown in fed-batch culture at the 15-L scale.

Medium Recipe (per liter fermentation medium):

[0597] The medium was generated using the following components per liter fermentation medium: K_2HPO_4 7.5 g, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, and 1000X modified trace metal solution 1 ml. All of the components were added together and dissolved in dH_2O . This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to volume. Glucose 10 g, thiamine $\cdot$ HCl 0.1 g, and antibiotics were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0598] The 1000X modified trace metal solution was generated using the following components: citric acids $\cdot$ H_2O 40 g, $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ 30 g, NaCl 10 g, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ 1 g, $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ 1 g, $\text{ZnSO} \cdot 7\text{H}_2\text{O}$ 1 g, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ 100 mg, H_3BO_3 100 mg, and $\text{NaMoO}_4 \cdot 2\text{H}_2\text{O}$ 100 mg. Each component is dissolved one at a time in $\text{Di H}_2\text{O}$, pH to 3.0 with HCl/NaOH, then q.s. to volume and filter sterilized with a 0.22 micron filter.

[0599] Fermentation was performed in a 15-L bioreactor with BL21 (DE3) *E. coli* cells containing the gi1.2 integrated lower MVA pathway described above and the pCL PtrcUpperMVA and pTrcKudzu plasmids. This experiment was carried out to monitor isoprene formation from glucose at the desired fermentation pH 7.0 and temperature 30°C. An inoculum of *E. coli* strain taken from a frozen vial was streaked onto an LB broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into tryptone-yeast extract medium. After the inoculum grew to OD 1.0, measured at 550 nm, 500 mL was used to inoculate a 5-L bioreactor.

[0600] Glucose was fed at an exponential rate until cells reached the stationary phase. After this time, the glucose feed was decreased to meet metabolic demands. The total amount of glucose delivered to the bioreactor during the 57 hour fermentation was 3.9 kg. Induction was achieved by adding IPTG. The IPTG concentration was brought to 100 μM when the

carbon dioxide evolution rate reached 100 mmol/L/hr. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 111A. The isoprene level in the off gas from the bioreactor was determined as described herein. The isoprene titer increased over the course of the fermentation to a final value of 1.6 g/L (Fig. 111B). The specific productivity of isoprene over the course of the fermentation is shown in Fig. 111C and peaked at 1.2 mg/OD/hr. The total amount of isoprene produced during the 57 hour fermentation was 16.2 g. The molar yield of utilized carbon that went into producing isoprene during fermentation was 0.9%. The weight percent yield of isoprene from glucose was 0.4%.

XIV. Production of isoprene from *E. coli* BL21 containing the kudzu isoprene synthase using glycerol as a carbon source

[0601] A 15-L scale fermentation of *E. coli* expressing Kudzu isoprene synthase was used to produce isoprene from cells fed glycerol in fed-batch culture. This experiment demonstrates that growing cells in the presence of glycerol (without glucose) resulted in the production of 2.2 mg/L of isoprene.

Medium Recipe (per liter fermentation medium):

[0602] The medium was generated using the following components per liter fermentation medium: K₂HPO₄ 7.5 g, MgSO₄ * 7H₂O 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, and 1000X modified trace metal solution 1 ml. All of the components were added together and dissolved in diH₂O. This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to volume. Glycerol 5.1 g, thiamine * HCl 0.1 g, and antibiotics were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0603] The medium was generated using the following components per liter fermentation medium: citric acids * H₂O 40 g, MnSO₄ * H₂O 30 g, NaCl 10 g, FeSO₄ * 7H₂O 1 g, CoCl₂ * 6H₂O 1 g, ZnSO * 7H₂O 1 g, CuSO₄ * 5H₂O 100 mg, H₃BO₃ 100 mg, and NaMoO₄ * 2H₂O 100 mg. Each component was dissolved one at a time in diH₂O, pH to 3.0 with HCl/NaOH, then q.s. to volume and filter sterilized with a 0.22 micron filter.

[0604] Fermentation was performed in a 15-L bioreactor with BL21 (DE3) *E. coli* cells containing the pTrcKudzu plasmid. This experiment was carried out to monitor isoprene formation from glycerol at the desired fermentation pH 7.0 and temperature 35°C. An inoculum of *E. coli* strain taken from a frozen vial was streaked onto an LA broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into soytone-yeast extract-glucose medium and grown at 35°C. After the inoculum grew to OD 1.0, measured at 550 nm, 600 mL was used to inoculate a 7.5-L bioreactor.

[0605] Glycerol was fed at an exponential rate until cells reached an optical density at 550 nm (OD₅₅₀) of 153. The total amount of glycerol delivered to the bioreactor during the 36 hour fermentation was 1.7 kg. Other than the glucose in the inoculum, no glucose was added to the bioreactor. Induction was achieved by adding IPTG. The IPTG concentration was brought to 20 uM when the OD₅₅₀ reached a value of 50. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 57. The isoprene level in the off gas from the bioreactor was determined as described herein. The isoprene titer increased over the course of the fermentation to a final value of 2.2 mg/L (Fig. 58). The total amount of isoprene produced during the 54 hour fermentation was 20.9 mg, and the time course of production is shown in Fig. 59.

[0606] XV. Isoprene fermentation from *E. coli* expressing genes from the mevalonic acid pathway and grown in fed-batch culture at the 15-L scale using invert sugar as a carbon source

[0607] A 15-L scale fermentation of *E. coli* expressing mevalonic acid pathway polypeptides and Kudzu isoprene synthase was used to produce isoprene from cells fed invert sugar in fed-batch culture. This experiment demonstrates that growing cells in the presence of invert sugar resulted in the production of 2.4 g/L of isoprene.

Medium Recipe (per liter fermentation medium):

[0608] The medium was generated using the following components per liter fermentation medium: K₂HPO₄ 7.5 g, MgSO₄ * 7H₂O 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, and 1000X Modified Trace Metal Solution 1 ml. All of the components were added together and dissolved in diH₂O. This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to

volume. Invert sugar 10 g, thiamine * HCl 0.1 g, and antibiotics were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0609] The 1000X modified trace metal solution was generated using the following components: citric acids * H₂O 40 g, MnSO₄ * H₂O 30 g, NaCl 10 g, FeSO₄ * 7H₂O 1 g, CoCl₂ * 6H₂O 1 g, ZnSO * 7H₂O 1 g, CuSO₄ * 5H₂O 100 mg, H₃BO₃ 100 mg, and NaMoO₄ * 2H₂O 100 mg. Each component is dissolved one at a time in Di H₂O, pH to 3.0 with HCl/NaOH, then q.s. to volume and filter sterilized with 0.22 micron filter.

[0610] Fermentation was performed in a 15-L bioreactor with BL21 (DE3) *E. coli* cells containing the pCL PtrcUpperMVA and pTrc KKDyIkIS plasmids. This experiment was carried out to monitor isoprene formation from invert sugar at the desired fermentation pH 7.0 and temperature 30°C. An inoculum of *E. coli* strain taken from a frozen vial was streaked onto an LB broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into tryptone-yeast extract medium. After the inoculum grew to OD 1.0, measured at 550 nm, 500 mL was used to inoculate a 5-L bioreactor.

[0611] Invert sugar was fed at an exponential rate until cells reached the stationary phase. After this time the invert sugar feed was decreased to meet metabolic demands. The total amount of invert sugar delivered to the bioreactor during the 44 hour fermentation was 2.4 kg. Induction was achieved by adding IPTG. The IPTG concentration was brought to 25 uM when the optical density at 550 nm (OD₅₅₀) reached a value of 9. The IPTG concentration was raised to 50 uM when OD₅₅₀ reached 200. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 96. The isoprene level in the off gas from the bioreactor was determined as described herein. The isoprene titer increased over the course of the fermentation to a final value of 2.4 g/L (Fig. 97). The total amount of isoprene produced during the 44 hour fermentation was 18.4 g and the time course of production is shown in Fig. 98. The molar yield of utilized carbon that went into producing isoprene during fermentation was 1.7%. The weight percent yield of isoprene from glucose was 0.8%.

Example 9. Construction of the upper and lower MVA pathway for integration into *Bacillus subtilis*

I. Construction of the Upper MVA pathway in *Bacillus subtilis*

[0612] The upper pathway from *Enterococcus faecalis* is integrated into *B. subtilis* under control of the *aprE* promoter. The upper pathway consists of two genes; *mvaE*, which encodes for AACT and HMGR, and *mvaS*, which encodes for HMGS. The two genes are fused together with a stop codon in between, an RBS site in front of *mvaS*, and are under the control of the *aprE* promoter. A terminator is situated after the *mvaE* gene. The chloramphenicol resistance marker is cloned after the *mvaE* gene and the construct is integrated at the *aprE* locus by double cross over using flanking regions of homology.

[0613] Four DNA fragments are amplified by PCR such that they contain overhangs that will allowed them to be fused together by a PCR reaction. PCR amplifications are carried out using Herculase polymerase according to manufacturer's instructions.

[0614] The product is digested with restriction endonucleases *PstI/BamHI* and ligated to pJM102 (Perego, M. 1993. Integrational vectors for genetic manipulation in *Bacillus subtilis*, p. 615–624. In A. L. Sonenshein, J. A. Hoch, and R. Losick (ed.), *Bacillus subtilis* and other gram-positive bacteria: biochemistry, physiology, and molecular genetics. American Society for Microbiology, Washington, D.C.) which is digested with *PstI/BamHI*. The ligation is transformed into *E. coli* TOP 10 chemically competent cells and transformants are selected on LA containing carbenicillin (50 µg/ml). The correct plasmid is identified by sequencing and is designated pJMUppperpathway2 (Figures 50 and 51). Purified plasmid DNA is transformed into *Bacillus subtilis aprEnprE Pxyl-comK* and transformants are selected on L agar containing chloramphenicol (5 µg/ml). A correct colony is selected and is plated sequentially on L agar containing chloramphenicol 10, 15 and 25 µg/ml to amplify the number of copies of the cassette containing the upper pathway.

[0615] The resulting strain is tested for mevalonic acid production by growing in LB containing 1% glucose and 1%. Cultures are analyzed by GC for the production of mevalonic acid.

[0616] This strain is used subsequently as a host for the integration of the lower mevalonic acid pathway.

[0617] The following primers are used to sequence the various constructs above.

Sequencing primers:

CF 07-134 (+) Start of *aprE* promoter PstI

CF 07-89 (+) Sequence *mvaS*

5'- GAAACCTACATCCAATCTTTTGCCC (SEQ ID NO:45)

[0618] Transformants are selected on LA containing chloramphenicol at a concentration of 5 µg/ml. One colony is confirmed to have the correct integration by sequencing and is plated on LA containing increasing concentrations of chloramphenicol over several days, to a final level of 25 µg/ml. This results in amplification of the cassette containing the genes of interest. The resulting strain is designated CF 455: pJMupperpathway#1 X *Bacillus subtilis aprEnprE Pxyl comK* (amplified to grow on LA containing chloramphenicol 25 µg/ml).

II. Construction of the Lower MVA pathway in *Bacillus subtilis*

[0619] The lower MVA pathway, consisting of the genes *mvk1*, *pmk*, *mpd* and *idi* are combined in a cassette consisting of flanking DNA regions from the *nprE* region of the *B. subtilis* chromosome (site of integration), the *aprE* promoter, and the spectinomycin resistance marker (see Figures 28 and 29). This cassette is synthesized by DNA2.0 and is integrated into the chromosome of *B. subtilis* containing the upper MVA pathway integrated at the *aprE* locus. The kudzu isoprene synthase gene is expressed from the replicating plasmid described in Example 4 and is transformed into the strain with both upper and lower pathways integrated.

Example 10: Exemplary isoprene compositions and methods of making them

I. Compositional analysis of fermentation off-gas containing isoprene

[0620] A 14 L scale fermentation was performed with a recombinant *E. coli* BL21 (DE3) strain containing two plasmids (pCL upperMev; pTrcKKDyIkIS encoding the full mevalonate pathway for isoprenoid precursor biosynthesis, an isoprenyl pyrophosphate isomerase from yeast, and an isoprene synthase from Kudzu. Fermentation off-gas from the 14 L tank was collected into 20 mL headspace vials at around the time of peak isoprene productivity (27.9 hours elapsed fermentation time, “EFT”) and analyzed by headspace GC/MS for volatile components.

[0621] Headspace analysis was performed with an Agilent 6890 GC/MS system fitted with an Agilent HP-5MS GC/MS column (30 m x 250 µm; 0.25 µm film thickness). A combiPAL autoinjector was used for sampling 500 µL aliquots from 20 mL headspace

vials. The GC/MS method utilized helium as the carrier gas at a flow of 1 mL/min. The injection port was held at 250 °C with a split ratio of 50:1. The oven temperature was held at 37 °C for an initial 2 minute period, followed an increase to 237 °C at a rate of 25 °C/min for a total method time of 10 minutes. The Agilent 5793N mass selective detector scanned from m/z 29 to m/z 300. The limit of detection of this system is approximately 0.1 $\mu\text{g}/\text{L}_{\text{gas}}$ or approximately 0.1 ppm. If desired, more sensitive equipment with a lower limit of detection may be used.

[0622] The off-gas consisted of 99.925 % (v/v) permanent gases (N_2 , CO_2 and O_2), approximately 0.075% isoprene (2-methyl-1,3-butadiene) (~750 ppmv, 2100 $\mu\text{g}/\text{L}$) and minor amounts (<50 ppmv) of ethanol, acetone, and two C5 prenyl alcohols. The amount of water vapor was not determined but was estimated to be equal to the equilibrium vapor pressure at 0 °C. The composition of the volatile organic fraction was determined by integration of the area under the peaks in the GC/MS chromatogram (Figs. 86A and 86B) and is listed in Table 6. Calibration curves for ethanol and acetone standards enabled the conversion of GC area to gas phase concentration in units of $\mu\text{g}/\text{L}$ using standard methods.

Table 6. Composition of volatile organic components in fermentation off-gas. The off-gas was analyzed at the 27.9 hour time point of a fermentation using an *E. coli* BL21 (DE3) strain expressing a heterologous mevalonate pathway, an isoprenyl pyrophosphate isomerase from yeast, and an isoprene synthase from Kudzu.

<i>Compound</i>	<i>RT (min)</i>	<i>GC area</i>	<i>Area %</i>	<i>Conc. ($\mu\text{g}/\text{L}$)</i>
Ethanol	1.669	239005	0.84	62 +/- 6
Acetone	1.703	288352	1.02	42 +/- 4
Isoprene (2-methyl-1,3-butadiene)	1.829	27764544	97.81	2000 +/- 200
3-methyl-3-buten-1-ol	3.493	35060	0.12	<10
3-methyl-2-buten-1-ol	4.116	58153	0.20	<10

II. Measurement of trace volatile organic compounds (VOCs) co-produced with isoprene during fermentation of a recombinant *E. coli* strain

[0623] A 14 L scale fermentation was performed with a recombinant *E. coli* BL21 (DE3) strain containing two plasmids (pCL upperMev; pTrcKKDyIkIS) encoding the full mevalonate pathway for isoprenoid precursor biosynthesis, an isoprenyl pyrophosphate isomerase from yeast, and an isoprene synthase from Kudzu.

[0624] Fermentation off-gas was passed through cooled headspace vials in order to concentrate and identify trace volatile organic components. The off-gas from this fermentation was sampled at a rate of 1 L/min for 10 minutes through a 20 mL headspace vial packed with quartz wool (2g) and cooled to -78°C with dry ice. The vial was recapped with a fresh vial cap and analyzed by headspace GC/MS for trapped VOCs using the conditions described in Example 10, part I. The ratios of compounds observed in Figs. 87A-87D are a combination of overall level in the fermentation off-gas, the relative vapor pressure at -78°C , and the detector response of the mass spectrometer. For example, the low level of isoprene relative to oxygenated volatiles (*e.g.*, acetone and ethanol) is a function of the high volatility of this material such that it does not accumulate in the headspace vial at -78°C .

[0625] The presence of many of these compounds is unique to isoprene compositions derived from biological sources. The results are depicted in Figs. 87A-87D and summarized in Tables 7A and 7B.

³ Ratio % is the peak area expressed as a % relative to the peak area of 2-methyl-1,3-butadiene.

III. Absence of C5 hydrocarbon isomers in isoprene derived from fermentation.

[0626] Cryo-trapping of isoprene present in fermentation off-gas was performed using a 2 mL headspace vial cooled in liquid nitrogen. The off-gas (1 L/min) was first passed through a 20 mL vial containing sodium hydroxide pellets in order to minimize the accumulation of ice and solid CO₂ in the 2 mL vial (-196 °C). Approximately 10L of off-gas was passed through the vial, after which it was allowed to warm to -78 °C with venting, followed by resealing with a fresh vial cap and analysis by GC/MS.

[0627] GC/MS headspace analysis was performed with an Agilent 6890 GC/MS system using a 100uL gas tight syringe in headspace mode. A Zebron ZB-624 GC/MS column (30 m x 250 µm; 1.40 µm film thickness) was used for separation of analytes. The GC autoinjector was fitted with a gas-tight 100 uL syringe, and the needle height was adjusted to allow the injection of a 50 uL headspace sample from a 2 mL GC vial. The GC/MS method utilized helium as the carrier gas at a flow of 1 mL/min. The injection port was held at 200 °C with a split ratio of 20:1. The oven temperature was held at 37 °C for the 5 minute duration of the analysis. The Agilent 5793N mass selective detector was run in single ion monitoring (SIM) mode on m/z 55, 66, 67 and 70. Under these conditions, isoprene was observed to elute at 2.966 minutes (Fig. 88B). A standard of petroleum derived isoprene (Sigma-Aldrich) was also analyzed using this method and was found to contain additional C5 hydrocarbon isomers, which eluted shortly before or after the main peak and were quantified based on corrected GC area (Fig. 88A).

Table 8A: GC/MS analysis of petroleum-derived isoprene

<i>Compound</i>	<i>RT (min)</i>	<i>GC area</i>	<i>Area % of total C5 hydrocarbons</i>
2-methyl-1-butene	2.689	18.2 x 10 ³	0.017%
(Z)-2-pentene	2.835	10.6x 10 ⁴	0.101%
Isoprene	2.966	10.4x 10 ⁷	99.869%
1,3-cyclopentadiene (CPD)	3.297	12.8 x 10 ³	0.012%

Table 8B: GC/MS analysis of fermentation-derived isoprene (% total C5 hydrocarbons)

<i>Compound</i>	<i>RT (min)</i>	<i>Corrected GC Area</i>	<i>% of total C5 hydrocarbons</i>
Isoprene	2.966	8.1 x 10 ⁷	100%

[0628] In a separate experiment, a standard mixture of C5 hydrocarbons was analyzed to determine if the detector response was the same for each of the compounds. The

compounds were 2-methyl-1-butene, 2-methyl-1,3-butadiene, (E)-2-pentene, (Z)-2-pentene and (E)-1,3-pentadiene. In this case, the analysis was performed on an Agilent DB-Petro column (100 m x 0.25 mm, 0.50 μ m film thickness) held at 50 °C for 15 minutes. The GC/MS method utilized helium as the carrier gas at a flow of 1 mL/min. The injection port was held at 200 °C with a split ratio of 50:1. The Agilent 5793N mass selective detector was run in full scan mode from m/z 19 to m/z 250. Under these conditions, a 100 μ g/L concentration of each standard produced the same detector response within experimental error.

IV. Compositions comprising isoprene adsorbed to a solid phase.

[0629] Biologically-produced isoprene was adsorbed to activated carbon resulting in a solid phase containing 50 to 99.9% carbon, 0.1% to 50% isoprene, 0.01% to 5% water, and minor amounts (<0.1%) of other volatile organic components.

[0630] Fermentation off-gas was run through a copper condensation coil held at 0 °C, followed by a granulated silica desiccant filter in order to remove water vapor. The dehumidified off-gas was then run through carbon containing filters (Koby Jr, Koby Filters, MA) to the point at which breakthrough of isoprene was detected in the filter exhaust by GC/MS. The amount of isoprene adsorbed to the cartridge can be determined indirectly by calculating the concentration in the off-gas, the overall flow rate and the percent breakthrough over the collection period. Alternately the adsorbed isoprene can be recovered from the filters by thermal, vacuum, or solvent-mediated desorption.

[0631] V. Collection and analysis of condensed isoprene.

[0632] Fermentation off-gas is dehumidified, and the CO₂ removed by filtration through a suitable adsorbant (*e.g.*, ascarite). The resulting off-gas stream is then run through a liquid nitrogen-cooled condenser in order to condense the VOCs in the stream. The collection vessel contains t-butyl catechol to inhibit the resulting isoprene condensate. The condensate is analyzed by GC/MS and NMR in order to determine purity using standard methods, such as those described herein.

[0633] VI. Production of prenyl alcohols by fermentation

[0634] Analysis of off-gas from an *E. coli* BL21 (DE3) strain expressing a Kudzu isoprene synthase revealed the presence of both isoprene and 3-methyl-3-buten-1-ol (isoprenol). The levels of the two compounds in the fermentation off-gas over the fermentation are shown in Fig. 89 as determined by headspace GC/MS. Levels of isoprenol (3-methyl-3-buten-1-ol, 3-MBA) attained was nearly 10 ug/L_{offgas} in this experiment. Additional experiments produced levels of approximately 20 ug/L_{offgas} in the fermentation off-gas.

Example 11: The de-coupling of growth and production of isoprene in *E. coli* expressing genes from the mevalonic acid pathway and fermented in a fed-batch culture

[0635] Example 11 illustrates the de-coupling of cell growth from mevalonic acid and isoprene production.

I. Fermentation Conditions

Medium Recipe (per liter fermentation medium):

[0636] The medium was generated using the following components per liter fermentation medium: K₂HPO₄ 7.5 g, MgSO₄ * 7H₂O 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, and 1000X modified trace metal solution 1 ml. All of the components were added together and dissolved in diH₂O. This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to volume. Glucose 10 g, thiamine * HCl 0.1 g, and antibiotics were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0637] The 1000X modified trace metal solution was generated using the following components: citric acids * H₂O 40 g, MnSO₄ * H₂O 30 g, NaCl 10 g, FeSO₄ * 7H₂O 1 g, CoCl₂ * 6H₂O 1 g, ZnSO * 7H₂O 1 g, CuSO₄ * 5H₂O 100 mg, H₃BO₃ 100 mg, and NaMoO₄ * 2H₂O 100 mg. Each component was dissolved one at a time in Di H₂O, pH to 3.0 with HCl/NaOH, then q.s. to volume, and filter sterilized with a 0.22 micron filter.

[0638] Fermentation was performed with *E. coli* cells containing the pTrcHis2AUpperPathway (also called pTrcUpperMVA, FIGs. 91 and 92A-92C) (50 µg/ml carbenicillin) or the pCL PtrcUpperMVA (also called pCL PtrcUpperPathway (Fig. 26)) (50 µg/ml spectinomycin) plasmids. For experiments in which isoprene was

produced, the *E. coli* cells also contained the pTrc KKDyIkIS (50 µg/ml kanamycin) plasmid. These experiments were carried out to monitor mevalonic acid or isoprene formation from glucose at the desired fermentation pH 7.0 and temperature 30°C. An inoculum of an *E. coli* strain taken from a frozen vial was streaked onto an LA broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into tryptone-yeast extract medium. After the inoculum grew to optical density 1.0 when measured at 550 nm, it was used to inoculate the bioreactor.

[0639] Glucose was fed at an exponential rate until cells reached the stationary phase. After this time the glucose feed was decreased to meet metabolic demands. Induction was achieved by adding IPTG. The mevalonic acid concentration in fermentation broth was determined by applying perchloric acid (Sigma-Aldrich # 244252) treated samples (0.3 M incubated at 4°C for 5 minutes) to an organic acids HPLC column (BioRad # 125-0140). The concentration was determined by comparing the broth mevalonic acid peak size to a calibration curve generated from mevalonolacetone (Sigma-Aldrich # M4667) treated with perchloric acid to form D,L-mevalonate. The isoprene level in the off gas from the bioreactor was determined as described herein. The isoprene titer is defined as the amount of isoprene produced per liter of fermentation broth.

II. Mevalonic acid production from *E. coli* BL21 (DE3) cells expressing the pTrcUpperMVA plasmid at a 150-L scale

[0640] BL21 (DE3) cells that were grown on a plate as explained above in Example 11, part I were inoculated into a flask containing 45 mL of tryptone-yeast extract medium and incubated at 30°C with shaking at 170 rpm for 5 hours. This solution was transferred to a 5-L bioreactor of tryptone-yeast extract medium, and the cells were grown at 30 °C and 27.5 rpm until the culture reached an OD₅₅₀ of 1.0. The 5 L of inoculum was seeded into a 150-L bioreactor containing 45-kg of medium. The IPTG concentration was brought to 1.1 mM when the OD₅₅₀ reached a value of 10. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 60A. The mevalonic acid titer increased over the course of the fermentation to a final value of 61.3 g/L (Fig. 60B). The specific productivity profile throughout the fermentation is shown in Fig. 60C and a comparison to Fig. 60A illustrates the de-coupling of growth and mevalonic acid production. The total amount of mevalonic acid produced during the 52.5 hour fermentation was 4.0 kg from 14.1 kg of utilized

glucose. The molar yield of utilized carbon that went into producing mevalonic acid during fermentation was 34.2%.

III. Mevalonic acid production from *E. coli* BL21 (DE3) cells expressing the pTrcUpperMVA plasmid at a 15-L scale

[0641] BL21 (DE3) cells that were grown on a plate as explained above in Example 11, part I were inoculated into a flask containing 500 mL of tryptone-yeast extract medium and grown at 30 °C at 160 rpm to OD₅₅₀ 1.0. This material was seeded into a 15-L bioreactor containing 4.5-kg of medium. The IPTG concentration was brought to 1.0 mM when the OD₅₅₀ reached a value of 10. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 61A. The mevalonic acid titer increased over the course of the fermentation to a final value of 53.9 g/L (Fig. 61B). The specific productivity profile throughout the fermentation is shown in Fig. 61C and a comparison to Fig. 61A illustrates the de-coupling of growth and mevalonic acid production. The total amount of mevalonic acid produced during the 46.6 hour fermentation was 491 g from 2.1 kg of utilized glucose. The molar yield of utilized carbon that went into producing mevalonic acid during fermentation was 28.8%.

IV. Mevalonic acid production from *E. coli* FM5 cells expressing the pTrcUpperMVA plasmid at a 15-L scale

[0642] FM5 cells that were grown on a plate as explained above in Example 11, part I were inoculated into a flask containing 500 mL of tryptone-yeast extract medium and grown at 30 °C at 160 rpm to OD₅₅₀ 1.0. This material was seeded into a 15-L bioreactor containing 4.5-kg of medium. The IPTG concentration was brought to 1.0 mM when the OD₅₅₀ reached a value of 30. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 62A. The mevalonic acid titer increased over the course of the fermentation to a final value of 23.7 g/L (Fig. 62B). The specific productivity profile throughout the fermentation is shown in Fig. 62C and a comparison to Fig. 62A illustrates the de-coupling of growth and mevalonic acid production. The total amount of mevalonic acid produced during the 51.2 hour fermentation was 140 g from 1.1 kg of utilized glucose. The molar yield of utilized carbon that went into producing mevalonic acid during fermentation was 15.2%.

V. Isoprene production from *E. coli* BL21 (DE3) cells expressing the pCL PTrcUpperMVA and pTrc KKDYIkIS plasmids at a 15-L scale

[0643] BL21 (DE3) cells expressing the pCL PtrcUpperMVA and pTrc KKDyIkIS plasmids that were grown on a plate as explained above in Example 11, part I were inoculated into a flask containing 500 mL of tryptone-yeast extract medium and grown at 30 °C at 160 rpm to OD₅₅₀ 1.0. This material was seeded into a 15-L bioreactor containing 4.5-kg of medium. The IPTG concentration was brought to 25 µM when the OD₅₅₀ reached a value of 10. The IPTG concentration was raised to 50 uM when OD₅₅₀ reached 190. The IPTG concentration was raised to 100 uM at 38 hours of fermentation. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 63A. The isoprene titer increased over the course of the fermentation to a final value of 2.2 g/L broth (Fig. 63B). The specific productivity profile throughout the fermentation is shown in Fig. 63C and a comparison to Fig. 63A illustrates the de-coupling of growth and isoprene production. The total amount of isoprene produced during the 54.4 hour fermentation was 15.9 g from 2.3 kg of utilized glucose. The molar yield of utilized carbon that went into producing isoprene during fermentation was 1.53%.

VI. Isoprene production from *E. coli* BL21 (DE3) tuner cells expressing the pCL PtrcUpperMVA and pTrc KKDyIkIS plasmids at a 15-L scale

[0644] BL21 (DE3) tuner cells expressing the pCL PtrcUpperMVA and pTrc KKDyIkIS plasmids that were grown on a plate as explained above in Example 11, part I were inoculated into a flask containing 500 mL of tryptone-yeast extract medium and grown at 30 °C at 160 rpm to OD₅₅₀ 1.0. This material was seeded into a 15-L bioreactor containing 4.5-kg of medium. The IPTG concentration was brought to 26 µM when the OD₅₅₀ reached a value of 10. The IPTG concentration was raised to 50 uM when OD₅₅₀ reached 175. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 64A. The isoprene titer increased over the course of the fermentation to a final value of 1.3 g/L broth (Fig. 64B). The specific productivity profile throughout the fermentation is shown in Fig. 64C and a comparison to Fig. 64A illustrates the de-coupling of growth and isoprene production. The total amount of isoprene produced during the 48.6 hour fermentation was 9.9 g from 1.6 kg of utilized glucose. The molar yield of utilized carbon that went into producing isoprene during fermentation was 1.34%.

VII. Isoprene production from *E. coli* MG1655 cells expressing the pCL PtrcUpperMVA and pTrc KKDyIkIS plasmids at a 15-L scale

[0645] MG1655 cells expressing the pCL PtrcUpperMVA and pTrc KKDyIkIS plasmids that were grown on a plate as explained above in Example 11, part I were inoculated into a flask containing 500 mL of tryptone-yeast extract medium and grown at 30 °C at 160 rpm to OD₅₅₀ 1.0. This material was seeded into a 15-L bioreactor containing 4.5-kg of medium. The IPTG concentration was brought to 24 µM when the OD₅₅₀ reached a value of 45. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 65A. The isoprene titer increased over the course of the fermentation to a final value of 393 mg/L broth (Fig. 65B). The specific productivity profile throughout the fermentation is shown in Fig. 65C and a comparison to Fig. 65A illustrates the de-coupling of growth and isoprene production. The total amount of isoprene produced during the 67.4 hour fermentation was 2.2 g from 520 g of utilized glucose. The molar yield of utilized carbon that went into producing isoprene during fermentation was 0.92%.

VIII. Isoprene production from *E. coli* MG1655ack-pta cells expressing the pCL PtrcUpperMVA and pTrc KKDyIkIS plasmids at a 15-L scale

[0646] MG1655ack-pta cells expressing the pCL PtrcUpperMVA and pTrc KKDyIkIS plasmids that were grown on a plate as explained above in Example 11, part I were inoculated into a flask containing 500 mL of tryptone-yeast extract medium and grown at 30 °C at 160 rpm to OD₅₅₀ 1.0. This material was seeded into a 15-L bioreactor containing 4.5-kg of medium. The IPTG concentration was brought to 30 µM when the OD₅₅₀ reached a value of 10. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 66A. The isoprene titer increased over the course of the fermentation to a final value of 368 mg/L broth (Fig. 66B). The specific productivity profile throughout the fermentation is shown in Fig. 66C and a comparison to Fig. 66A illustrates the de-coupling of growth and isoprene production. The total amount of isoprene produced during the 56.7 hour fermentation was 1.8 g from 531 g of utilized glucose. The molar yield of utilized carbon that went into producing isoprene during fermentation was 0.73%.

IX. Isoprene production from *E. coli* FM5 cells expressing the pCL PtrcUpperMVA and pTrc KKDyIkIS plasmids at a 15-L scale

[0647] FM5 cells expressing the pCL PtrcUpperMVA and pTrc KKDyIkIS plasmids that were grown on a plate as explained above in Example 11, part I were inoculated into a flask containing 500 mL of tryptone-yeast extract medium and grown at 30 °C at 160 rpm

to OD₅₅₀ 1.0. This material was seeded into a 15-L bioreactor containing 4.5-kg of medium. The IPTG concentration was brought to 27 μ M when the OD₅₅₀ reached a value of 15. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 67A. The isoprene titer increased over the course of the fermentation to a final value of 235 mg/L broth (Fig. 67B). The specific productivity profile throughout the fermentation is shown in Fig. 67C and a comparison to Fig. 67A illustrates the de-coupling of growth and isoprene production. The total amount of isoprene produced during the 52.3 hour fermentation was 1.4 g from 948 g of utilized glucose. The molar yield of utilized carbon that went into producing isoprene during fermentation was 0.32%.

Example 12: Production of isoprene during the exponential growth phase of *E. coli* expressing genes from the mevalonic acid pathway and fermented in a fed-batch culture

[0648] Example 12 illustrates the production of isoprene during the exponential growth phase of cells.

Medium Recipe (per liter fermentation medium):

[0649] The medium was generated using the following components per liter fermentation medium: K₂HPO₄ 7.5 g, MgSO₄ * 7H₂O 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, and 1000X modified trace metal solution 1 ml. All of the components were added together and dissolved in diH₂O. This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to volume. Glucose 10 g, thiamine * HCl 0.1 g, and antibiotics were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0650] The 1000X modified trace metal solution was generated using the following components: citric acids * H₂O 40 g, MnSO₄ * H₂O 30 g, NaCl 10 g, FeSO₄ * 7H₂O 1 g, CoCl₂ * 6H₂O 1 g, ZnSO * 7H₂O 1 g, CuSO₄ * 5H₂O 100 mg, H₃BO₃ 100 mg, and NaMoO₄ * 2H₂O 100 mg. Each component is dissolved one at a time in Di H₂O, pH to 3.0 with HCl/NaOH, then q.s. to volume and filter sterilized with 0.22 micron filter.

[0651] Fermentation was performed in a 15-L bioreactor with ATCC11303 *E. coli* cells containing the pCL PtrcUpperMVA and pTrc KKDyIkIS plasmids. This experiment was

carried out to monitor isoprene formation from glucose at the desired fermentation pH 7.0 and temperature 30°C. An inoculum of *E. coli* strain taken from a frozen vial was streaked onto an LB broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into tryptone-yeast extract medium. After the inoculum grew to OD 1.0, measured at 550 nm, 500 mL was used to inoculate a 5-L bioreactor.

[0652] Glucose was fed at an exponential rate until cells reached the stationary phase. After this time the glucose feed was decreased to meet metabolic demands. The total amount of glucose delivered to the bioreactor during the 50 hour fermentation was 2.0 kg. Induction was achieved by adding IPTG. The IPTG concentration was brought to 25 uM when the optical density at 550 nm (OD₅₅₀) reached a value of 10. The IPTG concentration was raised to 50 uM when OD₅₅₀ reached 190. The OD₅₅₀ profile within the bioreactor over time is shown in Fig. 99. The isoprene level in the off gas from the bioreactor was determined as described herein. The isoprene titer increased over the course of the fermentation to a final value of 1.4 g/L (Fig. 100). The total amount of isoprene produced during the 50 hour fermentation was 10.0 g. The profile of the isoprene specific productivity over time within the bioreactor is shown in Fig. 101. The molar yield of utilized carbon that contributed to producing isoprene during fermentation was 1.1%. The weight percent yield of isoprene from glucose was 0.5%.

Example 13: Flammability modeling and testing of isoprene

I. Summary of flammability modeling and testing of isoprene

[0653] Flammability modeling and experiments were performed for various hydrocarbon/oxygen/nitrogen/water/carbon dioxide mixtures. This modeling and experimental tested was aimed at defining isoprene and oxygen/nitrogen flammability curves under specified steam and carbon monoxide concentrations at a fixed pressure and temperature. A matrix of the model conditions is shown in Table 4, and a matrix of the experiments performed is shown in Table 5.

Table 4. Summary of Modeled Isoprene Flammability

Series	Temperature (°C)	Pressure (psig)	Steam Concentration (wt%)	Carbon Dioxide Concentration (wt. %)	Isoprene Concentration (vol. %)	Oxygen Concentration (vol. %)
A	40	0	0	0	Varying	Varying
B	40	0	4	0	Varying	Varying
C	40	0	0	5	Varying	Varying
D	40	0	0	10	Varying	Varying
E	40	0	0	15	Varying	Varying
F	40	0	0	20	Varying	Varying
G	40	0	0	30	Varying	Varying

Table 5. Summary of Isoprene Flammability Tests

Series Number	Temperature (°C)	Pressure (psig)	Steam Concentration (vol. %)	Isoprene Concentration (vol. %)	Oxygen Concentration (vol. %)
1	40	0	0	Varying	Varying
2	40	0	4	Varying	Varying

II. Description of calculated adiabatic flame temperature (CAFT) model

[0654] Calculated adiabatic flame temperatures (CAFT) along with a selected limit flame temperature for combustion propagation were used to determine the flammability envelope for isoprene. The computer program used in this study to calculate the flame temperatures is the NASA Glenn Research Center CEA (Chemical Equilibrium with Applications) software.

[0655] There are five steps involved in determining the flammability envelope using an adiabatic flame temperature model for a homogeneous combustion mechanism (where both the fuel and oxidant are in the gaseous state): selection of the desired reactants, selection of the test condition, selection of the limit flame temperature, modification of the reactants, and construction of a flammability envelope from calculations.

[0656] In this first step, selection of desired reactants, a decision must be made as to the reactant species that will be present in the system and the quantities of each. In many cases the computer programs used for the calculations have a list of reactant and product species. If any of the data for the species to be studied are not found in the program, they may be obtained from other sources such as the JANAF tables or from the internet. In this

current model data for water, nitrogen, oxygen and carbon dioxide were present in the program database. The program database did not have isoprene as a species; therefore the thermodynamic properties were incorporated manually.

[0657] The next step is to decide whether the initial pressure and temperature conditions that the combustion process is taking place in. In this model the pressure was 1 atmosphere (absolute) and the temperature was 40°C, the boiling point of isoprene.

[0658] The limit flame temperature for combustion can be either selected based on theoretical principles or determined experimentally. Each method has its own limitations.

[0659] Based on prior studies, the limit flame temperatures of hydrocarbons fall in the range of 1000 K to 1500 K. For this model, the value of 1500 K was selected. This is the temperature at which the reaction of carbon monoxide to carbon dioxide (a highly exothermic reaction and constitutes a significant proportion of the flame energy) becomes self sustaining.

[0660] Once the limit flame temperature has been decided upon, model calculations are performed on the given reactant mixture (species concentrations) and the adiabatic flame temperature is determined. Flame propagation is considered to have occurred only if the temperature is greater than the limit flame temperature. The reactant mixture composition is then modified to create data sets for propagation and non-propagation mixtures.

[0661] This type of model shows good agreement with the experimentally determined flammability limits. Regions outside the derived envelope are nonflammable and regions within it are flammable. The shape of the envelope forms a nose. The nose of the envelope is related to the limiting oxygen concentration (LOC) for gaseous fuels.

III. Results from calculated adiabatic flame temperature (CAFT) model

[0662] Plotted in Figs. 68 through 74 are the CAFT model results for Series A to G, respectively. The figures plot the calculated adiabatic flame temperature (using the NASA CEA program) as a function of fuel concentration (by weight) for several oxygen/nitrogen ratios (by weight). The parts of the curve that are above 1500 K, the selected limit flame temperature, contain fuel levels sufficient for flame propagation. The results may be difficult to interpret in the form presented in Figs. 68 through 74. Additionally, the current

form is not conducive to comparison with experimental data which is generally presented in terms of volume percent.

[0663] Using Series A as an example the data in Fig. 68 can be plotted in the form of a traditional flammability envelope. Using Fig. 68 and reading across the 1500 K temperature line on the ordinate one can determine the fuel concentration for this limit flame temperature by dropping a tangent to the abscissa for each curve (oxygen to nitrogen ratio) that it intersects. These values can then be tabulated as weight percent of fuel for a given weight percent of oxidizer (Fig. 75A). Then knowing the composition of the fuel (100 wt.% isoprene) and the composition of the oxidizer (relative content of water, oxygen and nitrogen) molar quantities can be established.

[0664] From these molar quantities percentage volume concentrations can be calculated. The concentrations in terms of volume percent can then be plotted to generate a flammability envelope (Fig. 75B). The area bounded by the envelope is the explosible range and the area excluded is the non-explosible range. The “nose” of the envelope is the limiting oxygen concentration. Figs. 76A and 76B contain the calculated volume concentrations for the flammability envelope for Series B generated from data presented in Fig. 69. A similar approach can be used on data presented in Figs. 70-74.

IV. Flammability testing experimental equipment and procedure

[0665] Flammability testing was conducted in a 4 liter high pressure vessel. The vessel was cylindrical in shape with an inner diameter of 6” and an internal height of 8.625”. The temperature of the vessel (and the gases inside) was maintained using external heaters that were controlled by a PID controller. To prevent heat losses, ceramic wool and reflective insulation were wrapped around the pressure vessel. Type K thermocouples were used to measure the temperature of the gas space as well as the temperature of the vessel itself. Fig. 77 illustrates the test vessel.

[0666] Before a test was ran, the vessel was evacuated and purged with nitrogen to ensure that any gases from previous tests were removed. A vacuum was then pulled on the vessel. The pressure after this had been done was typically around 0.06 bar(a). Due to the nitrogen purging, the gas responsible for this initial pressure was assumed to be nitrogen. Using partial pressures, water, isoprene, nitrogen, and oxygen were then added in the appropriate amounts to achieve the test conditions in question. A magnetically driven

mixing fan within the vessel ensured mixing of the gaseous contents. The gases were allowed to mix for about 2 minutes with the fan being turned off approximately 1 minute prior to ignition.

[0667] The igniter was comprised of a 1.5 ohm nicrome coil and an AC voltage source on a timer circuit. Using an oscilloscope, it was determined that 34.4 VAC were delivered to the igniter for 3.2 seconds. A maximum current of 3.8 amps occurred approximately halfway into the ignition cycle. Thus, the maximum power was 131 W and the total energy provided over the ignition cycle was approximately 210 J.

[0668] Deflagration data was acquired using a variable reluctance Validyne DP215 pressure transducer connected to a data acquisition system. A gas mixture was considered to have deflagrated if the pressure rise was greater than or equal to 5%.

V. Results of flammability testing

[0669] The first experimental series (Series 1) was run at 40°C and 0 psig with no steam. Running tests at varying concentrations of isoprene and oxygen produced the flammability curve shown in Fig. 78A. The data points shown in this curve are only those that border the curve. A detailed list of all the data points taken for this series is shown in Figs. 80A and 80B.

[0670] Fig. 78B summarizes the explosibility data points shown in Fig. 78A. Fig. 78C is a comparison of the experimental data with the CAFT model predicted flammability envelope. The model agrees very well with the experimental data. Discrepancies may be due to the non-adiabatic nature of the test chamber and limitations of the model. The model looks at an infinite time horizon for the oxidation reaction and does not take into consideration any reaction kinetic limitation.

[0671] Additionally, the model is limited by the number of equilibrium chemical species that are in its database and thus may not properly predict pyrolytic species. Also, the flammability envelope developed by the model uses one value for a limit flame temperature (1500K). The limit flame temperature can be a range of values from 1,000K to 1,500K depending on the reacting chemical species. The complex nature of pyrolytic chemical species formed at fuel concentrations above the stoichiometric fuel/oxidizer level

is one reason why the model may not accurately predict the upper flammable limit for this system.

[0672] The second experimental series (Series 2) was run at 40°C and 0 psig with a fixed steam concentration of 4%. Running tests at varying concentrations of isoprene and oxygen produced the flammability curve shown in Fig. 79A. The data points shown in this curve are only those that border the curve. A detailed list of all the data points taken for this series is shown in Fig. 81. Due to the similarity between the data in Series 1 only the key points of lower flammable limit, limiting oxygen concentration, and upper flammable limits were tested. The addition of 4% steam to the test mixture did not significantly change the key limits of the flammability envelope. It should be noted that higher concentrations of steam/water and or other inertants may influence the flammability envelope.

[0673] Fig. 79B summarizes the explosibility data points shown in Fig. 79A. Fig. 79C is a comparison of the experimental data with the CAFT model predicted flammability envelope. The model agrees very well with the experimental data. Discrepancies may be due to the same factors described in Series 1

V. Calculation of Flammability Limits of Isoprene in Air at 3 Atmospheres of Pressure

[0674] The methods described in Example 13, parts I to IV were also used to calculate the flammability limits of isoprene at an absolute system pressure of 3 atmospheres and 40°C. These results were compared to those of Example 13, parts I to IV at an absolute system pressure of 1 atmosphere and 40°C. This higher pressure was tested because the flammability envelope expands or grows larger as the initial system pressure is increased. The upper flammability limit is affected the most, followed by the limiting oxygen composition. The lower flammability limit is the least affected (*see*, for example, “Bulletin 627 – Flammability Characteristics of Combustible Gases and Vapors” written by Michael G. Zabetakis and published by the former US Bureau of Mines (1965), which is hereby incorporated by reference in its entirety, particular with respect to the calculation of flammability limits).

[0675] In Figure 82, the calculated adiabatic flame temperature is plotted as a function of isoprene (fuel) concentration, expressed in weight percent of the total fuel/nitrogen/oxygen, where the system pressure was initially 3 atmospheres. The

calculated flame temperatures are very similar to those determined initially in the 1 atmosphere system (Fig. 83). As a result, when flammability envelopes are generated using the calculated adiabatic flammability data, the curves are very similar (see Figs. 84 and 85). Therefore, based on these theoretical calculations, a system pressure increase from 1 atmosphere to 3 atmosphere does not result in a significant increase/broadening of the flammability envelope. If desired, these model results may be validated using experimental testing (such as the experimental testing described herein at a pressure of 1 atmosphere).

VII. Summary of flammability studies

[0676] A calculated adiabatic temperature model was developed for the flammability envelope of the isoprene/oxygen/nitrogen/water/ carbon dioxide system at 40°C and 0 psig. The CAFT model that was developed agreed well with the experimental data generated by the tests conducted in this work. The experimental results from Series 1 and 2 validated the model results from Series A and B.

Example 14: Expression Constructs and Strains

I. Construction of plasmids encoding mevalonate kinase.

[0677] A construct encoding the *Methanosarcina mazei* lower MVA pathway (Accession numbers NC_003901.1, NC_003901.1, NC_003901.1, and NC_003901.1, which are each hereby incorporated by reference in their entireties) was synthesized with codon optimization for expression in *E. coli*. This construct is named *M. mazei* archeal Lower Pathway operon (Figures 112A-112C; SEQ ID NO:102) and encodes *M. mazei* MVK, a putative decarboxylase, IPK, and IDI enzymes. The gene encoding MVK (Accession number NC_003901.1) was PCR amplified using primers MCM165 and MCM177 (Table 11) using the Strategene Herculanase II Fusion kit according to the manufacturer's protocol using 30 cycles with an annealing temperature of 55°C and extension time of 60 seconds. This amplicon was purified using a Qiagen PCR column and then digested at 37°C in a 10 µL reaction with PmeI (in the presence of NEB buffer 4 and BSA). After one hour, NsiI and Roche buffer H were added for an additional hour at 37°C. The digested DNA was purified over a Qiagen PCR column and ligated to a similarly digested and purified plasmid MCM29 (MCM29 is *E. coli* TOP10 (Invitrogen) transformed with pTrcKudzu encoding Kudzu isoprene synthase) in an 11 uL reaction 5uL Roche Quick Ligase buffer

1, 1 uL buffer 2, 1 uL plasmid, 3 uL amplicon, and 1 uL ligase (1 hour at room temperature). MCM 29 is pTrcKudzuKan. The ligation reaction was introduced into Invitrogen TOP10 cells and transformants selected on LA/kan50 plates incubated at 37 °C overnight. The MVK insert in the resulting plasmid MCM382 was sequenced (Figures 113A-113C; SEQ ID NO: 103).

II. Creation of strains overexpressing mevalonate kinase and isoprene synthase.

[0678] Plasmid MCM382 was transformed into MCM331 cells (which contain chromosomal construct gi1.2KKDyI encoding *S. cerevisiae* mevalonate kinase, mevalonate phosphate kinase, mevalonate pyrophosphate decarboxylase, and IPP isomerase) that had been grown to midlog in LB medium and washed three times in iced, sterile water. One μ L of DNA was added to 50 μ L of cell suspension, and this mixture was electroporated in a 2 mm cuvette at 2.5 volts, 25 uFd followed immediately by recovery in 500 μ L LB medium for one hour at 37°C. Transformant was selected on LA/kan50 and named MCM391. Plasmid MCM82 was introduced into this strain by the same electroporation protocol followed by selection on LA/kan50/spec50. The resulting strain MCM401 contains a cmp-marked chromosomal construct gi1.2KKDyI, kan-marked plasmid MCM382, and spec-marked plasmid MCM82 (which is pCL PtrcUpperPathway encoding *E. faecalis* mvaE and mvaS). See Table 12.

III. Construction of plasmid MCM376 - MVK from *M. mazei* archeal Lower in pET200D.

[0679] The MVK ORF from the *M. mazei* archeal Lower Pathway operon (Figures 112A-112C; SEQ ID NO:102) was PCR amplified using primers MCM161 and MCM162 (Table 11) using the Invitrogen Platinum HiFi PCR mix. 45 uL of PCR mix was combined with 1 uL template, 1 uL of each primer at 10 uM, and 2 uL water. The reaction was cycled as follows: 94°C for 2:00; 30 cycles of 94°C for 0:30, 55°C for 0:30, and 68°C for 1:15; and then 72°C for 7:00, and 4°C until cool. 3 uL of this PCR reaction was ligated to Invitrogen pET200D plasmid according to the manufacturer's protocol. 3 uL of this ligation was introduced into Invitrogen TOP10 cells, and transformants were selected on LA/kan50. A plasmid from a transformant was isolated and the insert sequenced, resulting in MCM376 (Figures 114A-114C; SEQ ID NO:108).

V. Creation of expression strain MCM378.

[0680] Plasmid MCM376 was transformed into Invitrogen BL21(DE3) pLysS cells according to the manufacturer's protocol. Transformant MCM378 was selected on LA/kan50.

Example 15: Production of isoprene by *E. coli* expressing the upper mevalonic acid (MVA) pathway, the integrated lower MVA pathway (gi1.2KKDyI), mevalonate kinase from *M. mazei*, and isoprene synthase from Kudzu and grown in fed-batch culture at the 20 mL batch scale

Medium Recipe (per liter fermentation medium)

[0681] Each liter of fermentation medium contained K₂HPO₄ 13.6 g, KH₂PO₄ 13.6 g, MgSO₄ * 7H₂O 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, (NH₄)₂SO₄ 3.2 g, yeast extract 1 g, and 1000X Trace Metal Solution 1 ml. All of the components were added together and dissolved in diH₂O. The pH was adjusted to 6.8 with ammonium hydroxide (30%) and brought to volume. Media was filter sterilized with a 0.22 micron filter. Glucose (2.5 g) and antibiotics were added after sterilization and pH adjustment.

1000X Trace Metal Solution:

[0682] 1000X Trace Metal Solution contained citric Acids * H₂O 40 g, MnSO₄ * H₂O 30 g, NaCl 10 g, FeSO₄ * 7H₂O 1 g, CoCl₂ * 6H₂O 1 g, ZnSO₄ * 7H₂O 1 g, CuSO₄ * 5H₂O 100

mg, H₃BO₃ 100 mg, and NaMoO₄ * 2H₂O 100 mg. Each component was dissolved one at a time in di H₂O, pH to 3.0 with HCl/NaOH, then brought to volume and filter sterilized with a 0.22 micron filter.

Strains:

[0683] MCM343 cells are BL21 (DE3) *E. coli* cells containing the upper mevalonic acid (MVA) pathway (pCL Upper), the integrated lower MVA pathway (gi1.2KKDyI), and isoprene synthase from Kudzu (pTrcKudzu).

[0684] MCM401 cells are BL21 (DE3) *E. coli* cells containing the upper mevalonic acid (MVA) pathway (pCL PtrcUpperPathway), the integrated lower MVA pathway (gi1.2KKDyI), and high expression of mevalonate kinase from *M. mazei* and isoprene synthase from Kudzu (pTrcKudzuMVK(M.mazei)).

[0685] Isoprene production was analyzed by growing the strains in 100 mL bioreactors with a 20 mL working volume at a temperature of 30°C. An inoculum of *E. coli* strain taken from a frozen vial was streaked onto an LB broth agar plate (with antibiotics) and incubated at 30°C. A single colony was inoculated into media and grown overnight. The bacteria were diluted into 20 mL of media to reach an optical density of 0.05 measured at 550 nm. The 100 mL bioreactors were sealed, and air was pumped through at a rate of 8 mL/min. Adequate agitation of the media was obtained by stirring at 600 rpm using magnetic stir bars. The off-gas from the bioreactors was analyzed using an on-line Hiden HPR-20 mass spectrometer. Masses corresponding to isoprene, CO₂, and other gasses naturally occurring in air were monitored. Accumulated isoprene and CO₂ production were calculated by summing the concentration (in percent) of the respective gasses over time. Atmospheric CO₂ was subtracted from the total in order to estimate the CO₂ released due to metabolic activity.

[0686] Isoprene production from a strain expressing the full mevalonic acid pathway and Kudzu isoprene synthase (MCM343) was compared to a strain that in addition over-expressed MVK from *M. mazei* and Kudzu isoprene synthase (MCM401) in 100 mL bioreactors. The bacteria were grown under identical conditions in defined media with glucose as carbon source. Induction of isoprene production was achieved by adding isopropyl-beta-D-1-thiogalactopyranoside (IPTG) to a final concentration of either 100 uM or 200 uM. Off-gas measurements revealed that the strain over-expressing both MVK

and isoprene synthase (MCM401) produced significantly more isoprene compared to the strain expressing only the mevalonic acid pathway and Kudzu isoprene synthase (MCM343) as shown in Figures 115A-115D. At 100 μ M induction, the MCM401 strain produced 2-fold more isoprene compared to the MCM343 strain. At 200 μ M IPTG induction, the MCM401 strain produced 3.4-fold more isoprene when compared to the MCM343 strain. Analysis of CO₂ in the off-gas from the bioreactors, which is a measure of metabolic activity, indicates that metabolic activity was independent from IPTG induction and isoprene production.

[0687] Example 16: Production of isoprene by *E. coli* expressing the upper mevalonic acid (MVA) pathway, the integrated lower MVA pathway (gi1.2KKDyI), mevalonate kinase from *M. mazei*, and isoprene synthase from Kudzu and grown in fed-batch culture at the 15-L scale

Medium Recipe (per liter fermentation medium):

[0688] Each liter of fermentation medium contained K₂HPO₄ 7.5 g, MgSO₄ * 7H₂O 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, and 1000X Modified Trace Metal Solution 1 ml. All of the components were added together and dissolved in DI H₂O. This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to volume. Glucose 10 g, thiamine * HCl 0.1 g, and antibiotics were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0689] 1000X Modified Trace Metal Solution contained citric Acids * H₂O 40 g, MnSO₄ * H₂O 30 g, NaCl 10 g, FeSO₄ * 7H₂O 1 g, CoCl₂ * 6H₂O 1 g, ZnSO₄ * 7H₂O 1 g, CuSO₄ * 5H₂O 100 mg, H₃BO₃ 100 mg, and NaMoO₄ * 2H₂O 100 mg. Each component was dissolved one at a time in DI H₂O, pH to 3.0 with HCl/NaOH, then q.s. to volume and filter sterilized with a 0.22 micron filter.

[0690] Fermentation was performed in a 15-L bioreactor with BL21 (DE3) *E. coli* cells containing the upper mevalonic acid (MVA) pathway (pCL PtrcUpperPathway encoding *E. faecalis* mvaE and mvaS), the integrated lower MVA pathway (gi1.2KKDyI encoding *S. cerevisiae* mevalonate kinase, mevalonate phosphate kinase, mevalonate pyrophosphate decarboxylase, and IPP isomerase), and high expression of mevalonate kinase from *M.*

mazei and isoprene synthase from Kudzu (pTrcKudzuMVK(*M.mazei*)). This experiment was carried out to monitor isoprene formation from glucose at the desired fermentation pH 7.0 and temperature 30°C. An inoculum of *E. coli* strain taken from a frozen vial was streaked onto an LB broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into tryptone-yeast extract medium. After the inoculum grew to OD 1.0, measured at 550 nm, 500 mL was used to inoculate 5-L of medium in a 15-L bioreactor.

[0691] Glucose was fed at an exponential rate until cells reached the stationary phase. After this time the glucose feed was decreased to meet metabolic demands. The total amount of glucose delivered to the bioreactor during the 68 hour fermentation was 3.8 kg. Induction was achieved by adding isopropyl-beta-D-1-thiogalactopyranoside (IPTG). The IPTG concentration was brought to 51 uM when the optical density at 550 nm (OD₅₅₀) reached a value of 9. The IPTG concentration was raised to 88 uM when OD₅₅₀ reached 149. Additional IPTG additions raised the concentration to 119 uM at OD₅₅₀ = 195 and 152 uM at OD₅₅₀ = 210. The OD₅₅₀ profile within the bioreactor over time is shown in Figure 116. The isoprene level in the off gas from the bioreactor was determined using a Hiden mass spectrometer. The isoprene titer increased over the course of the fermentation to a final value of 23.8 g/L (Figure 117). The total amount of isoprene produced during the 68 hour fermentation was 227.2 g and the time course of production is shown in Figure 118. The metabolic activity profile, as measured by TCER, is shown in Figure 119. The total viable count (total colony forming units) decreased by two orders of magnitude between 10 and 39 hours of fermentation (Figure 120). The molar yield of utilized carbon that went into producing isoprene during fermentation was 13.0%. The weight percent yield of isoprene from glucose was 6.3%.

Example 17: Production of isoprene by *E. coli* expressing the upper mevalonic acid (MVA) pathway, the integrated lower MVA pathway (gi1.2KKDyI), mevalonate kinase from *M. mazei*, and isoprene synthase from Kudzu and grown in fed-batch culture at the 15-L scale (2x 100µM IPTG induction)

Medium Recipe (per liter fermentation medium):

[0692] Each liter of fermentation medium contained K₂HPO₄ 7.5 g, MgSO₄ * 7H₂O 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, and 1000X

Modified Trace Metal Solution 1 ml. All of the components were added together and dissolved in DI H₂O. This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to volume. Glucose 10 g, thiamine * HCl 0.1 g, and antibiotics were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0693] 1000X Modified Trace Metal Solution contained citric Acids * H₂O 40 g, MnSO₄ * H₂O 30 g, NaCl 10 g, FeSO₄ * 7H₂O 1 g, CoCl₂ * 6H₂O 1 g, ZnSO₄ * 7H₂O 1 g, CuSO₄ * 5H₂O 100 mg, H₃BO₃ 100 mg, and NaMoO₄ * 2H₂O 100 mg. Each component was dissolved one at a time in DI H₂O, pH to 3.0 with HCl/NaOH, then q.s. to volume and filter sterilized with a 0.22 micron filter.

[0694] Fermentation was performed in a 15-L bioreactor with BL21 (DE3) *E. coli* cells containing the upper mevalonic acid (MVA) pathway (pCL PtrcUpperPathway encoding *E. faecalis* mvaE and mvaS), the integrated lower MVA pathway (gi1.2KKDyI encoding *S. cerevisiae* mevalonate kinase, mevalonate phosphate kinase, mevalonate pyrophosphate decarboxylase, and IPP isomerase), and high expression of mevalonate kinase from *M. mazei* and isoprene synthase from Kudzu (pTrcKudzuMVK(*M. mazei*)). This experiment was carried out to monitor isoprene formation from glucose at the desired fermentation pH 7.0 and temperature 30°C. An inoculum of *E. coli* strain taken from a frozen vial was streaked onto an LB broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into tryptone-yeast extract medium. After the inoculum grew to OD 1.0, measured at 550 nm, 500 mL was used to inoculate 5-L medium in a 15-L bioreactor.

[0695] Glucose was fed at an exponential rate until cells reached the stationary phase. After this time the glucose feed was decreased to meet metabolic demands. The total amount of glucose delivered to the bioreactor during the 55 hour fermentation was 1.9 kg. Induction was achieved by adding isopropyl-beta-D-1-thiogalactopyranoside (IPTG). The IPTG concentration was brought to 111 uM when the optical density at 550 nm (OD₅₅₀) reached a value of 9. The IPTG concentration was raised to 193 uM when OD₅₅₀ reached 155. The OD₅₅₀ profile within the bioreactor over time is shown in Figure 121. The isoprene level in the off gas from the bioreactor was determined using a Hiden mass spectrometer. The isoprene titer increased over the course of the fermentation to a final value of 19.5 g/L (Figure 122). The total amount of isoprene produced during the 55 hour fermentation was

133.8 g and the time course of production is shown in Figure 123. Instantaneous volumetric productivity levels reached values as high as 1.5 g isoprene/L broth/hr (Figure 124). Instantaneous yield levels reached as high as 17.7% w/w (Figure 125). The metabolic activity profile, as measured by TCER, is shown in Figure 126. The total viable count (total colony forming units) decreased by two orders of magnitude between 8 and 36 hours of fermentation (Figure 127). The molar yield of utilized carbon that went into producing isoprene during fermentation was 15.8%. The weight percent yield of isoprene from glucose over the entire fermentation was 7.4%.

[0696] In addition, as a control, fermentation was performed in a 15-L bioreactor with BL21 (DE3) *E. coli* cells containing the upper mevalonic acid (MVA) pathway (pCL PtrcUpperPathway encoding *E. faecalis* mvaE and mvaS), the integrated lower MVA pathway (gi1.2KKDyI encoding *S. cerevisiae* mevalonate kinase, mevalonate phosphate kinase, mevalonate pyrophosphate decarboxylase, and IPP isomerase), and high expression of mevalonate kinase from *M. mazei* and isoprene synthase from Kudzu (pTrcKudzuMVK(*M.mazei*)). This experiment was carried out to monitor uninduced cell metabolic activity as measured by CER from glucose at the desired fermentation pH 7.0 and temperature 30°C. An inoculum of *E. coli* strain (MCM401 described above) taken from a frozen vial was streaked onto an LB broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into tryptone-yeast extract medium. After the inoculum grew to OD 1.0, measured at 550 nm, 500 mL was used to inoculate 5-L medium in a 15-L bioreactor. Glucose was fed at an exponential rate until cells reached the stationary phase. After this time the glucose feed was decreased to meet metabolic demands.

[0697] Figure 148 compares the CER profiles for the uninduced cells described above and the cells induced by adding isopropyl-beta-D-1-thiogalactopyranoside (IPTG) in Examples 16 and 17.

[0698] Example 18: Production of isoprene by *E. coli* expressing the upper mevalonic acid (MVA) pathway, the integrated lower MVA pathway (gi1.2KKDyI), mevalonate kinase from *M. mazei*, and isoprene synthase from Kudzu and grown in fed-batch culture at the 15-L scale (1x 50µM IPTG + 150µM IPTG fed induction)

Medium Recipe (per liter fermentation medium):

[0699] Each liter of fermentation medium contained K_2HPO_4 7.5 g, $MgSO_4 \cdot 7H_2O$ 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, and 1000X Modified Trace Metal Solution 1 ml. All of the components were added together and dissolved in diH_2O . This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to volume. Glucose 10 g, thiamine $\cdot HCl$ 0.1 g, and antibiotics were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0700] 1000X Modified Trace Metal Solution contained citric Acids $\cdot H_2O$ 40 g, $MnSO_4 \cdot H_2O$ 30 g, NaCl 10 g, $FeSO_4 \cdot 7H_2O$ 1 g, $CoCl_2 \cdot 6H_2O$ 1 g, $ZnSO_4 \cdot 7H_2O$ 1 g, $CuSO_4 \cdot 5H_2O$ 100 mg, H_3BO_3 100 mg, and $NaMoO_4 \cdot 2H_2O$ 100 mg. Each component was dissolved one at a time in DI H_2O , pH to 3.0 with HCl/NaOH, then q.s. to volume and filter sterilized with a 0.22 micron filter.

[0701] Fermentation was performed in a 15-L bioreactor with BL21 (DE3) *E. coli* cells containing the upper mevalonic acid (MVA) pathway (pCL PtrcUpperPathway encoding *E. faecalis* mvaE and mvaS), the integrated lower MVA pathway (gi1.2KKDyI encoding *S. cerevisiae* mevalonate kinase, mevalonate phosphate kinase, mevalonate pyrophosphate decarboxylase, and IPP isomerase), and high expression of mevalonate kinase from *M. mazei* and isoprene synthase from Kudzu (pTrcKudzuMVK(*M. mazei*)). This experiment was carried out to monitor isoprene formation from glucose at the desired fermentation pH 7.0 and temperature 30°C. An inoculum of *E. coli* strain taken from a frozen vial was streaked onto an LB broth agar plate (with antibiotics) and incubated at 37°C. A single colony was inoculated into tryptone-yeast extract medium. After the inoculum grew to OD 1.0, measured at 550 nm, 500 mL was used to inoculate 5-L medium in a 15-L bioreactor.

[0702] Glucose was fed at an exponential rate until cells reached the stationary phase. After this time the glucose feed was decreased to meet metabolic demands. The total amount of glucose delivered to the bioreactor during the 55 hour fermentation was 2.2 kg. Induction was achieved by adding isopropyl-beta-D-1-thiogalactopyranoside (IPTG). The IPTG concentration was brought to 51 μM when the optical density at 550 nm (OD_{550}) reached a value of 10. In addition to the IPTG spike, at $OD_{550} = 10$ a constant feed began and delivered 164 mg of IPTG over 18 hours. The OD_{550} profile within the bioreactor over time is shown in Figure 128. The isoprene level in the off gas from the bioreactor was

determined using a Hiden mass spectrometer. The isoprene titer increased over the course of the fermentation to a final value of 22.0 g/L (Figure 129). The total amount of isoprene produced during the 55 hour fermentation was 170.5 g and the time course of production is shown in Figure 130. The metabolic activity profile, as measured by TCER, is shown in Figure 131. When the airflow to the bioreactor was decreased from 8 slpm to 4 slpm for a period of about 1.7 hours, the concentration of isoprene in the offgas increased from 0.51 to 0.92 w/w % (Figure 132). These elevated levels of isoprene did not appear to have any negative impact on cell metabolic activity as measured by the total carbon dioxide evolution rate (TCER), since TCER declined only 7% between 37.2 and 39.3 hours (Figure 132). The total viable count (total colony forming units) decreased by two orders of magnitude between 7 and 36 hours of fermentation (Figure 133). The molar yield of utilized carbon that went into producing isoprene during fermentation was 16.6%. The weight percent yield of isoprene from glucose over the entire fermentation was 7.7%.

Example 19: The effect of externally applied isoprene on a wild-type *E. coli* grown in fed-batch culture at the 1-L scale

Medium Recipe (per liter fermentation medium):

[0703] Each liter of fermentation medium contained K_2HPO_4 7.5 g, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ 2 g, citric acid monohydrate 2 g, ferric ammonium citrate 0.3 g, yeast extract 0.5 g, and 1000X Modified Trace Metal Solution 1 ml. All of the components were added together and dissolved in dH_2O . This solution was autoclaved. The pH was adjusted to 7.0 with ammonium hydroxide (30%) and q.s. to volume. Glucose 10 g, thiamine * HCl 0.1 g, and antibiotics were added after sterilization and pH adjustment.

1000X Modified Trace Metal Solution:

[0704] 1000X Modified Trace Metal Solution contained citric Acids * H_2O 40 g, $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ 30 g, NaCl 10 g, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ 1 g, $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ 1 g, $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ 1 g, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ 100 mg, H_3BO_3 100 mg, and $\text{NaMoO}_4 \cdot 2\text{H}_2\text{O}$ 100 mg. Each component was dissolved one at a time in DI H_2O , pH to 3.0 with HCl/NaOH, then q.s. to volume and filter sterilized with a 0.22 micron filter.

[0705] Fermentation was performed in a 1-L bioreactor with BL21 (DE3) *E. coli* cells. This experiment was carried out to monitor the effects of isoprene on cell viability and

metabolic activity in a glucose fed-batch bioreactor at the desired fermentation pH 7.0 and temperature 30°C. An inoculum of *E. coli* strain from a frozen vial was inoculated into tryptone-yeast extract medium. After the inoculum grew to OD 1.0, measured at 550 nm, 50 mL was used to inoculate 0.5-L medium in a 1-L bioreactor.

[0706] Glucose was fed at an exponential rate until cells reached the stationary phase. After this time the glucose feed was fed to meet metabolic demands. Isoprene was fed into the bioreactor using nitrogen gas as a carrier. The rate of isoprene feeding was 1 g/L/hr during mid-growth phase (OD₅₅₀ = 31-44) and lasted for a total of 75 minutes (13.2 to 14.4 hours). The OD₅₅₀ profile within the bioreactor over time is shown in Figure 134. The metabolic activity profile, as measured by TCER, is shown in Figure 135. The total viable count (total colony forming units) increased by 14-fold during the period when isoprene was introduced into the bioreactor (Figure 136).

Example 20: Production of isoprene and expression of isoprene synthase by *Saccharomyces cerevisiae*

[0707] The Kudzu isoprene synthase enzyme was optimized for expression according to a hybrid *Saccharomyces cerevisiae*/*Pichia pastoris* codon usage table, synthesized, and cloned into pDONR221:19430 (by DNA 2.0, Figure 140 for map and Figure 141 for sequence (SEQ ID NO:115)). A Gateway® Cloning (Invitrogen) reaction was performed according to the manufacturer's protocol: Since pDONR221:19430 was an "entry" vector, the LR Clonase II enzyme (the LR Reaction) was used to introduce the codon-optimized isoprene synthase into the "destination" vector pYES-DEST52 (Invitrogen).

[0708] The LR Reaction was then transformed into Top10 chemically competent cells (Invitrogen) according to the manufacturer's protocol, and bacteria harboring pYES-DEST52 plasmids with the isoprene synthase ORF were selected for on LA plates containing 50 µg/ml carbenicillin. Individual positive transformants were tested by colony PCR (see below for primer concentrations and thermocycling parameters) using illustra PuReTaq Ready-To-Go™ PCR Beads (GE Healthcare) with the T7 forward primer and the Yeast isoprene synthase -Rev2 primer (See Table 13).

Table 13. Primer sequences for amplifying isoprene synthase.

Primer Name	Sequence (5' to 3')	Purpose
-------------	---------------------	---------

Yeast HGS -For2	CACCAAAGACTTCATAGACT (SEQ ID NO:116)	Forward primer for yeast optimized isoprene synthase
Yeast HGS -Rev2	AGAGATATCTTCCTGCTGCT (SEQ ID NO:117)	Reverse primer for yeast optimized isoprene synthase
T7 Forward	TAATACGACTCACTATAGGG (SEQ ID NO:118)	PCR and sequencing primer

[0709] Plasmids that yielded a PCR fragment of the correct size (1354 bp) were purified by miniprep (Qiagen) and sent for sequencing (Quintara Biosciences, Berkeley, CA) with the T7 Forward and Yeast isoprene synthase-For2 primers (*See* Table 13). Results from sequencing runs were compared to the known sequence of pDONR221:19430 (using Vector NTI software, Invitrogen), and a single plasmid, pDW14, was selected for further study (Figure 142A for map and Figures 142B and C for the complete sequence (SEQ ID NO:119)). The sequence of pDW14 diverged from that of pDONR221:19430 by a single nucleotide (marked in bold in Figure 142B). The single nucleotide change (G to A) did not result in a change in the ORF, since it was in the third position of a lysine-encoding codon.

[0710] Purified pDW14 was transformed into *Saccharomyces cerevisiae* strain INVSc-1 using the protocol described in the S. c. EasyComp Transformation kit (Invitrogen). INVSc-1 strains harboring pDW14 or pYES-DEST52 (which contains an intact URA3 gene) were selected for and maintained on SC Minimal Medium with 2% glucose without uracil, as described in the pYES-DEST52 Gateway Vector manual (Invitrogen). Two independent isolates of INVSc-1 containing pDW14 and a single control strain with pYES-DEST52 were chosen for further analysis.

[0711] To induce isoprene synthase expression, cultures were grown overnight in liquid SC Minimal Medium. The cultures were then diluted to an OD₆₀₀ of approximately 0.2 and grown for 2-3 hours. Cultures were spun by centrifugation, washed once, resuspended in an equal volume (10 ml) of SC minimal medium with 1% raffinose, 2% galactose without uracil, and grown overnight to induce the expression of isoprene synthase. The OD₆₀₀ of the strains was determined (Figure 144A), and strains were harvested by centrifugation and resuspended in 2 ml of lysis buffer (a 1:1 mix of 50% glycerol and PEB pH 7.4: Tris Base 2.423 g/L, MgCl₂ (Anhydrous) 1.904 g/L, KCl 14.910 g/L, DTT 0.154 g/L, Glycerol 50 mL/L).

[0712] The lysis mixtures were passed through a french press three times, and lysates were analyzed by SDS-PAGE. For Coomassie gel analysis (Fig. 143A), samples were diluted

1:1 with 2X SDS loading buffer with reducing agent, loaded (20 μ l total volume) onto a 4-12% bis-tris gel, run in MES buffer, and stained using SimplyBlue SafeStain according to the manufacturer's protocol (the Invitrogen Novex system).

[0713] The WesternBreeze kit (Invitrogen) was used for transfer and chromogenic detection of isoprene synthase on a nitrocellulose membrane. The primary antibody was 1799A 10 week diluted 1:1000 in Invitrogen antibody diluent. Primary antibody binding was followed by development with a secondary antibody labeled with Alexa Fluor 488 (Invitrogen Catalog No. A-11008) to permit quantitative signal determination. The western blot procedure was carried out as described by Invitrogen. The fluorescence signal was recorded with a Molecular Dynamics Storm instrument using the blue filter setting and quantitatively analyzed with the Molecular Dynamics ImageQuant image analysis software package. Specific activity of the library members was calculated from the ratio of the amount of isoprene produced divided by either the A600 of the induction cultures or the isoprene synthase protein concentration determined by western blot. Figure 143B shows that isoprene synthase was present in the induced INVSc-1 strains harboring pDW14 (lanes 2 and 3) in comparison to the control harboring pYES-DEST52 (lane 1).

[0714] The DMAPP assay for isoprene synthase headspace was performed on 25 μ L of the lysate from each strain for which 5 μ L 1 M $MgCl_2$, 5 μ L 100 mM DMAPP, and 65 μ L 50 mM Tris pH 8 were added. The reaction was performed at 30°C for 15 minutes in a gas tight 1.8 mL GC tube. Reactions were terminated by addition of 100 μ L 250 mM EDTA pH 8. Figure 144B showed the specific activity values (in μ g HG/L/OD) of the induced strains harboring pDW14 in comparison to the control. Induced strains harboring pDW14 displayed approximately 20X higher activity than the control lacking isoprene synthase.

PCR Cycling Parameters

[0715] Illustra PuReTaq Ready-To-Go™ PCR Beads (GE Healthcare) were used with oligonucleotide primer pairs at a concentration of 0.4 μ M each in 25 μ l total volume/reaction. For analysis of plasmids resulting from the LR Clonase reaction (Invitrogen), a small amount of bacteria from individual colonies on a selective plate was added to each tube containing the PCR mix described above. The reaction cycle was as follows: 1) 95°C for 4 minutes; 2) 95°C for 20 seconds; 3) 52°C for 20 seconds; 4) 72°C

for 30 seconds; 5 cycles of steps 2 through 4; 5) 95°C for 20 seconds; 6) 55°C for 20 seconds; 7) 72°C for 30 seconds; 25 cycles of steps 5 through 7, 72°C for 10 minutes, and 4°C until cool.

Example 21: Production of isoprene in *Pseudomonas* and other Gram negative bacteria

Construction of pBBR5HGSOpt2_2, conjugation in *Pseudomonas* and measurement of isoprene synthase activity

[0716] A gene encoding isoprene synthase from *Pueraria lobata* (Kudzu plant) was codon-optimized for different microbial species of interest (Table 14; fluo-opt2v2 was the sequence chosen) and was synthesized by DNA2.0, Menlo Park, CA. The map and sequence of fluo-opt2v2 can be found in Figures 145A and 145B (SEQ ID NO:120). HindIII and BamHI restriction sites were added to the synthesized sequence for easier cloning, and a RBS was added in front of the ATG to enhance transcription.

[0717] Number of rare codons, as a function of the microbial species, in different versions of codon-optimized isoprene synthase from *Pueraria lobata*. Several rounds of optimization led to a gene with no rare codons in the all the species of interest.

Table 14. Number of rare codons.

Organism	fluo-opt1 (quote)	fluo-opt2	fluo-opt3	E. coli opt	fluo-opt2v2
<i>Pseudomonas fluorescens</i> Pf-5	19	X	X	57	0
<i>Phodopseudomonas palustris</i> CGA009	37	13	3	74	0
<i>Pseudomonas putida</i> F1	0	0	0	29	0
<i>Corynebacterium glutamicum</i> (ATCC)	4 (Ser)	0	0	0	0
<i>Pseudomonas fluorescens</i> PfO-1	1 (Val)	0	0	57	0

[0718] The gene was provided by DNA2.0 in a cloning vector. The vector was digested with HindIII/BamHI, the band corresponding to the insert of interest was gel-purified, and relegated with HindIII/BamHI-digested pBBR1MCS5 (Kovach et al, *Gene* 166:175-176, 1995, which is incorporated by reference in its entirety, particularly with respect to pBBR1MCS5), Figure 146A for map and 146B and C for sequence (SEQ ID NO:121). This resulted in plasmid pBBR5HGSOpt2_2 (Figure 147A for map and 147B and C for sequence (SEQ ID NO:122)) in which isoprene synthase was expressed from the lac promoter presented in pBBR1MCS5.

[0719] The vector was transformed in *E. coli* S17-1 and mated with *Pseudomonas putida* F1 ATCC700007 and *Pseudomonas fluorescens* ATCC 13525. After conjugation on LB, selection for plasmid-harboring *Pseudomonas* strains was on M9 + 16 mM sodium citrate +Gentamicin 50 ug/ml. Presence of the plasmid in the strains thus generated was checked by plasmid preparation using the Qiagen kit (Valencia, CA).

[0720] Isoprene synthase activities of the recombinant strains *P. putida*, pBBR5HGSOpt2_2 and *P. fluorescens*, pBBR5HGSOpt2_2 were assayed by growing the strains in TM3 medium (as described in Example 1 Part II) + 10 g/L glucose, harvesting the biomass in mid-log phase, breaking the cells by French Press and proceeding with the DMAPP assay. Results of the assay were presented in Table 15. The presence of activity measured by the DMAPP assay confirmed that isoprene synthase was expressed in *Pseudomonas*.

[0721] Isoprene synthase activity was examined in *Pseudomonas putida* and *Pseudomonas fluorescens* expressing isoprene synthase from the lac promoter, using plasmid pBBR5HGSOpt2_2

Table 15. Isoprene synthase activity in *Pseudomonas putida* and *Pseudomonas fluorescens*.

Strain	OD	Isoprene synthase activity mg isoprene/(L.h.OD)
<i>P. fluorescens</i> , pBBR5HGSOpt2_2	1.46	0.96
<i>P. putida</i> , pBBR5HGSOpt2_2	3.44	0.65
Control (<i>P. putida</i> w/o plasmid)	8.32	To be determined

Example 22: Growth of *E. coli* and *Pseudomonas* strains on sugar cane compared to glucose, and expression of isoprene synthase using both substrates

I. Preparation of liquid sugar cane

[0722] Crystallized raw cane sugar was dissolved in water in the following way: 750 g H₂O was added to 250 g sugar. The solution was stirred and gently heated until dissolution. Some material was not soluble. The weight of the solution was adjusted to 1 kg after dissolution to replenish the evaporated water. The volume of the solution was measured to be 940 mL. Hence the concentration of the solution was 265 g/L. The product label claimed 14 g of carbohydrate for 15 g of raw sugar cane. Hence the carbohydrate concentration of the solution was 248 g/L. Dry solids were measured to be 24.03 %, close enough of the expected 250 g/kg. pH of the solution was 5.49. Glucose concentration was measured using an enzymatic/spectrophotometric assay, with glucose oxidase. The glucose concentration was 17.4 g/L.

[0723] As a majority of microorganisms do not use sucrose, but can use glucose and fructose, the solution was split in two. One half was autoclaved once for 30 minutes (sugar cane as is). Some inversion resulted, as the glucose content increased to 29.75 g/L (*See* Fig. 149). The other half of the solution was adjusted to pH 4.0 using phosphoric acid, then the solution was inverted by autoclaving (inverted sugar cane). Three cycles of 30 min were sufficient to obtain complete inversion, as shown on Fig. 149. Both solutions were used for the growth curves described below.

II. Growth curves of different strains of *E. coli* and *Pseudomonas* on sugar cane compared to glucose

[0724] One colony of each of the strains presented in Table 16 was inoculated in 25 ml TM3 + 10 g/L glucose, and was grown overnight at 30°C and 200 rpm. TM3 is described in Example 7, Section II. The morning after, 1 ml of each culture was used to inoculate flasks containing 25 mL TM3 and 10 g/L glucose, 10 g/L sugar cane as is, or 10 g/L inverted sugar cane (sugar cane solutions described above). The flasks were incubated at 30°C and 200 rpm and samples were taken regularly to measure OD₆₀₀. Figures 150 and 151 show that growth rate and biomass yield were comparable for glucose and inverted sugar cane, both for *Pseudomonas* and *E. coli* strains. *P. fluorescens* showed some signs of being able to use sugar cane which has not been inverted too.

Table 16. Strains used in this study.

	Strain
<i>Escherichia coli</i>	BL21
	MG1655
	ATCC11303
	B REL 606
<i>Pseudomonas</i>	<i>putida</i> F1 (ATCC700007)
	<i>Fluorescens</i> (ATCC13525)

III. Comparison of isoprene production from *E. coli* expressing isoprene synthase when grown on glucose or sugar cane

[0725] *E. coli* MCM401 (BL21(DE3)) containing full MVA pathway, mevalonate kinase from *M. mazei* and isoprene synthase from *Pueraria lobata*, as described in Example 14, Section II was grown in TM3 + either 10 g/L glucose or 10 g/L inverted sugar cane (based on carbohydrate concentration of the syrup). Flasks were inoculated from an overnight culture on TM3 + 10 g/L glucose at an $OD_{600} = 0.2$. Antibiotics were added where needed. After two hours, the *E. coli* cultures were induced with 400 μ M IPTG. After 6 hours of growth, isoprene production and isoprene synthase activities, using the DMAPP assay as described in Example 2B, were measured. Results are presented in Table 17 and illustrate clearly that inverted sugar cane is equivalent to glucose in terms of isoprene and isoprene synthase production on a per cell basis.

Table 17.

Strain	Carbon Source	OD	Isoprene synthase activity mg isoprene/(L.h.OD)	Isoprene production mg isoprene/(L.h.OD)
MCM401	Glucose	2.20	21.06	8.98
MCM401	Sugar cane inverted	2.32	20.20	9.23

[0726] Unless defined otherwise, the meanings of all technical and scientific terms used herein are those commonly understood by one of skill in the art to which this invention belongs. Singleton, *et al.*, Dictionary of Microbiology and Molecular Biology, 2nd ed., John Wiley and Sons, New York (1994), and Hale & Marham, The Harper Collins Dictionary of Biology, Harper Perennial, N.Y. (1991) provide one of skill with a general dictionary of many of the terms used in this invention. It is to be understood that this invention is not limited to the particular methodology, protocols, and reagents described, as these may vary. One of skill in the art will also appreciate that any methods and

materials similar or equivalent to those described herein can also be used to practice or test the invention.

[0727] The headings provided herein are not limitations of the various aspects or embodiments of the invention which can be had by reference to the specification as a whole.

[0728] For use herein, unless clearly indicated otherwise, use of the terms “a”, “an,” and the like refers to one or more.

[0729] Reference to “about” a value or parameter herein includes (and describes) embodiments that are directed to that value or parameter per se. For example, description referring to “about X” includes description of “X.” Numeric ranges are inclusive of the numbers defining the range.

[0730] It is understood that aspects and embodiments of the invention described herein include “comprising,” “consisting,” and “consisting essentially of” aspects and embodiments.

Example 23: Production of ethylene in *E. coli*

I. Construction of an ethylene-producing *E. coli* strain.

[0731] The product of the ethylene-forming enzyme (*efe*) gene from *Pseudomonas syringae* converts 2-oxoglutarate, an intermediate of the TCA cycle, into ethylene. Primers amplifying the bacterial *efe* gene were derived from the *efe* gene of *Pseudomonas syringae* pv. *glycinea* strain ICMP2189 (Acc.No. EF175870). The *efe* gene was amplified by PCR using primer pair *efe_rev*: 5' CGGACCGTCATGAGCCTGTCGCGCGGG-3' (SEQ ID NO:127), wherein TCA = stop-codon *efe*-gene, and *efe*-Pffh_oe: 5'-CCACCCCAGGCGAGAGACAATGACCAACCTACAGACTTTC-3' (SEQ ID NO:128), wherein ATG = start-codon *efe* gene, giving PCR-fragment A. Genomic DNA prepared from *Pseudomonas syringae* served as template.

[0732] The putative promoter region of the *ffh* gene of *E. coli* MG1655 encoding the protein component of the signal recognition particle was amplified by PCR using primer pair *Pffh_fwd*: 5'-CGGTCCGGAAAGAGAAGCAGTATAGCG-3' (SEQ ID NO:129) and *Pffh_oe*: 5'-GAAAGTCTGTAGGTTGGTCATTGTCTCTCGCCTGGGGTGG-3' (SEQ

ID NO:130), wherein CAT = start codon *ffh*-gene, to give PCR-fragment B. PCR fragment B covers 147 bp upstream of the start-codon of the *ffh*-gene and thus the putative *ffh*-promoter. PCR fragments A and B were spliced by overlap extension PCR generating a DNA fragment that encodes the *efe* gene under control of the *ffh*-promoter. After splicing the PCR-fragments A and B using primer pair Pffh_fwd and efe_rev, the blunt ended PCR product was cloned in vector pCR-zero-blunt (Invitrogen) to give plasmid pCR-blunt_Pffh-efe (Seq ID 1x, Figures 152A and 152B).

II. Production of ethylene by *E. coli*

[0733] *E. coli* DH5 α , pCRblunt-Pffh-efe was inoculated in 5 ml LB + 50 ppm Kanamycin and incubated overnight at 30 °C and 200 rpm. The morning after, it was inoculated in HM1 medium, pH 6.8 (Table 1x) containing 10 g/L glucose and 1 g/L yeast extract, to an OD600 of 0.1. The culture was incubated at 30 °C and 200 rpm. After 3 h incubation, 4 X 1 ml and 4 X 5 ml of culture were transferred in a 20 ml headspace vial sealed with a Teflon cap. After 7.5 h of incubation, another set of 4 X 5 mL of culture was transferred to a 20 ml headspace vial sealed with a Teflon cap. The vials were incubated at 30 °C and shaking at 200 rpm. At regular time intervals, a vial was removed and analyzed for ethylene concentration in the headspace, OD600 and organic acids.

Table 1x: HM1 medium composition

Compounds	Concentration (g/L)
K ₂ HPO ₄	13.6
KH ₂ PO ₄	13.6
MgSO ₄ * 7H ₂ O	2
Citric Acid Monohydrate	2
Ferric Ammonium Citrate	0.3
(NH ₄) ₂ SO ₄	3.2
Trace metal solution	1 ml

[0734] Ethylene was measured by GC/FID analysis with an Agilent 7890 GC instrument outfitted with a CTC PAL headspace autosampler. The GC column was a GS-GasPro column (30 m x 0.25 mm x 1 μ m) interfaced to a FID detector. The carrier gas was helium at a flow rate of 1.076 mL/min (28.8 cm/sec) with the injector port operated at a split ratio of 20:1, and the FID detector held at 260°C. Headspace samples (100 μ L/injection) were withdrawn from 20mL glass vials and analyzed using an isothermal program with an oven temperature set at 90°C for the 5 min run time. The method was calibrated using a 100

ppm ethylene in nitrogen standard gas mixture obtained from Scott Specialty Gases (PA, USA).

[0735] Organic acids were analyzed by HPLC (Ion exclusion column Aminex HPX-87H, 300 mm X 7.8 mm, 0.005 M H₂SO₄, 0.6 mL/min as the mobile phase). Succinate could not be detected by this method as its peak interfered with a component in the medium.

[0736] Figures 153, 154 and 155 present ethylene (mg/L headspace), OD, glucose (g/L), acetate (g/L) and lactate (g/L) concentration for the three sets of headspace vials incubation (Figure 153: 5 mL broth at OD 0.23; Figure 154: 1 mL broth at OD 0.23; Figure 155: 5 mL broth at OD 0.45). No ethylene was detected in control vials containing *E. coli* DH5 α only, with broth transferred to the vials at same OD and incubated for the same amount of time.

III. Recovery of ethylene from the headspace

[0737] Ethylene was recovered using adsorption on a silver-modified montmorillonite clay, as described by Cho *et al.* (*Korean J. Chem. Eng.* (2002) **19**(5), 821-826.). Fermentation off-gas was dehumidified and run into a silver-modified clay (Cho (2002)) filter in order to remove ethylene from the off-gas stream. The off-gas stream can be further treated before introduction into the silver-clay filter whereby carbon dioxide is scrubbed from the off-gas stream by sparging through an aqueous sodium hydroxide solution. Ethylene was desorbed from the silver-clay filter using a pressure swing cycle as described by Cho *et al.*

AJ457070

AY182241

CLAIMS

What is claimed is:

1. A method of producing isoprene, the method comprising:
 - a) culturing cells comprising one or more nucleic acids encoding for isoprene synthase polypeptide under suitable conditions for production of isoprene; and
 - b) producing isoprene, wherein the cells produce greater than about 400 nmole/g_{wcm}/hour of isoprene, and wherein the carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour.
2. The method of claim 1, further comprising recovering the isoprene.
3. The method of claim 1, wherein the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an isoprene synthase polypeptide.
4. The method of claim 1, wherein the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an IDI polypeptide, an MVA pathway enzyme, or a DXP pathway enzyme.
5. The method of claim 4 wherein the MVA pathway enzyme is mevalonate kinase.
6. The method of claim 1, wherein the isoprene synthase polypeptide is from *Pueraria* or *Populus* or a hybrid, *Populus alba* x *Populus tremula*.
7. The method of claim 6, wherein the isoprene synthase polypeptide is selected from the group consisting of *Pueraria montana* or *Pueraria lobata*, *Populus tremuloides*, *Populus alba*, *Populus nigra*, and *Populus trichocarpa*.
8. The method of claim 1, wherein the cells are gram-positive bacterial cells, *Streptomyces* cells, gram-negative bacterial cells, *Escherichia*

- cells, *Pantoea* cells, fungal cells, filamentous fungal cells, *Trichoderma* cells, *Aspergillus* cells, or yeast cells.
9. The method of claim 8, wherein the cells are selected from the group consisting of *Bacillus subtilis*, *Streptomyces lividans*, *Streptomyces coelicolor*, *Streptomyces griseus*, *Escherichia coli*, *Pantoea citrea*, *Trichoderma reesei*, *Aspergillus oryzae* and *Aspergillus niger*, *Saccharomyces cerevisiae* and *Yarrowia lipolytica*.
 10. A method of producing isoprene, the method comprising:
 - a) culturing cells comprising one or more nucleic acids encoding for isoprene synthase polypeptide under suitable conditions for production of isoprene; and
 - b) producing isoprene, wherein the liquid phase concentration of isoprene is less than about 1 g/L and the cells produce greater than about 400 nmole/g_{wcm}/hour of isoprene.
 11. The method of claim 10, further comprising recovering the isoprene.
 12. The method of claim 10, wherein the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an isoprene synthase polypeptide.
 13. The method of claim 10, wherein the cells further comprise one or more heterologous nucleic acids or one or more additional copies of an endogenous nucleic acid encoding an IDI polypeptide, an MVA pathway enzyme, or a DXP pathway enzyme.
 14. The method of claim 13 wherein the MVA pathway enzyme is mevalonate kinase.
 15. The method of claim 10, wherein the isoprene synthase polypeptide is from *Pueraria* or *Populus* or a hybrid, *Populus alba* x *Populus tremula*.
 16. The method of claim 10, wherein the cells are gram-positive bacterial cells, *Streptomyces* cells, gram-negative bacterial cells, *Escherichia* cells, *Pantoea* cells, fungal cells, filamentous fungal cells, *Trichoderma* cells, *Aspergillus* cells, or yeast cells.

17. A method of producing a compound, wherein the compound has one or more characteristics selected from the group consisting of (a) a Henry's law coefficient of less than about 250 M/atm and (b) a solubility in water of less than about 100 g/L, the method comprising:
 - a) culturing cells comprising one or more nucleic acids encoding for isoprene synthase polypeptide under suitable conditions for production of the compound, wherein a gas is added at a gas sparging rate between about 0.01 vvm to about 2 vvm; and
 - b) producing the compound.
18. The method of claim 17, further comprising recovering the compound.
19. The method of claims 17, wherein the compound produced is ethylene.
20. The method of claim 17, wherein the compound produced is isoprene.
21. Cells in culture comprising a nucleic acid encoding an isoprene synthase polypeptide, wherein the cells produce greater than about 400 nmole/g_{wcm}/hour of isoprene and carbon dioxide evolution rate of the cells is greater than about 1×10^{-18} mmol/L/hour.
22. A system comprising a reaction chamber with cells of claim 21.
23. A method of producing a compound, wherein the compound has one or more characteristics selected from the group consisting of (a) a Henry's law coefficient of less than about 250 M/atm and (b) a solubility in water of less than about 100 g/L, the method comprising:
 - a) culturing cells comprising one or more nucleic acids encoding for isoprene synthase polypeptide under suitable conditions for production of the compound, wherein the compound has one or more characteristics selected from the group consisting of (a) a Henry's law coefficient of less than about 250 M/atm and (b) a solubility in water of less than about 100 g/L;
 - b) producing the compound;
 - c) and recovering the compound from the gas phase.
24. The method of claim 23, wherein the compound produced is ethylene.

25. The method of claim 23, wherein the compound is isoprene.
