

Description

This invention relates to a well tool including a valve and a pressure-responsive latching mechanism.

It is well known that there is the need for a tester valve tool for use in a pipe string for controlling fluid flow, by which the pipe string can be pressure-tested to determine if there are any leaks in the pipe string. This is important so that any leaks can be detected relatively near the surface and fixed before higher pressure fluids are allowed to flow into or out of the pipe string. For example, such testing is needed prior to a squeeze-cementing or treating job. Because additional joints of pipe are added to the pipe string as the pipe string is lowered into the well, such testing often must be repeated so that the valve must be opened and closed several times before the ultimate work to be accomplished (e.g., the squeeze-cementing or treating job) is performed. After the testing is completed, however, the valve should be locked in a desired position, such as in an open position so that any subsequent, non-testing fluid flow is neither obstructed nor controlled by the tester valve. Therefore, there is the need for a tester valve with a locking or latching mechanism to lock the valve in such a desired position.

Tester valves of various types are well-known and types of valves which can be locked in an open or a closed position are also known; however, most of the locking or latching types of which we are aware are automatically operable in that locking or latching automatically occurs when the valve is moved to the position in which it is to be locked. That is, there is no additional controllable force required to be exerted on the latching device for it to operate once the valve is placed in the desired position. Thus, if such a valve is inadvertently moved to such locking position, it is automatically locked and cannot be unlocked until it is retrieved to the surface.

There is a need for latching mechanisms which must be positively acted upon or controlled other than by a passive biasing force which automatically operates as soon as the valve has moved to the locking position so that inadvertent (or even intentional) movement of the valve alone will not lock the valve. Such a positive acting force could be by annulus fluid pressure applied under control from the surface, for example.

US-A-4420045 and US-A-4421172, each corresponding to the preamble of claim 1, describe a tester tool for controlling fluid flow through a pipe string disposed in a well, comprising: a first valve housing portion having a first engagement shoulder defined therein; a second valve housing portion having a second engagement shoulder defined

therein, said second valve housing portion slidably connected with said first valve housing portions; a valve member movably retained within said first and second housing portions; and latch means, slidably disposed adjacent said first and second housing portions, for moving, in response to an applied pressure, between an unlatched position, wherein said first and second housing portions can move relative to each other, and a latched position, wherein said first and second housing portions are latched to prevent relative movement, said latch means having third and fourth engagement shoulders defined therein. These tester valve tools rely upon a reciprocating action between the first and second valve housing portions to operate both the valve member and the latch means.

We have now devised an improved well tool which reduces or overcomes the above noted disadvantages of the prior art.

According to the invention there is provided a tester tool for controlling fluid flow through a pipe string disposed in a well, characterised in that said third and fourth engagement shoulders engage said first and second engagement shoulders when said latch means is moved by the applied pressure to said latched position, and said latch means includes: a slide member having a surface defining said fourth engagement shoulder; a locking dog having a surface defining said third engagement shoulder; and retainer means for retaining said locking dog with said slide member so that said locking dog is moved by said slide member.

Preferably, the tool includes a reciprocating ball valve and may be used for pressure testing a pipe string as it is lowered into a well, for example. The latching mechanism requires a positive acting force to be applied thereto once the tool has been placed in the position in which it is to be locked. In a preferred embodiment the latching mechanism is responsive to either an internal pressure exerted through the pipe string or to an annular pressure exerted through the annulus between the pipe string and the well.

The tool of the present invention is preferably constructed so that it can be reset or released by simply removing only one threaded connector forming part of the latching mechanism, thereby obviating the need to further disassemble the whole tool. No J-slot is required; therefore, there need be no lug wear or other maintenance problems which may be associated with J-slots. A preferred embodiment valve of the present invention can, to a certain extent, be constructed of existing parts; however, it is more compactly constructed than at least some other types of tester valves so that material and machining costs are reduced. Fewer O-rings are used in the preferred embodiment, thereby also reducing cost and maintenance.

Broadly, the apparatus of the present invention includes a first support structure having means for connecting with a pipe string; a second support structure connected in relative axial sliding cooperation with the first support structure so that the tool is reciprocable between a first working position, wherein the first and second support structures are in a first relative position, and a second working position, wherein said first and second support structures are in a second relative position; and latch means slidably retained on the first and second support structures, for latching the first and second support structures together so that further relative axial movement therebetween is prevented when the latch means is axially moved into latching engagement with both of the first and second support structures. In the preferred embodiment, the latch means includes means for receiving an axially acting pressure so that the latch means moves in response thereto. This axially acting pressure can be exerted by a pressure applied through the pipe string or a pressure applied through the annulus.

More particularly, the latch means includes a latch member; a slide member having first engagement means for engaging the latch member and having second engagement means for engaging the second support structure; and biasing means for biasing the latch member into latching engagement with the first support structure when the slide member moves so that the second engagement means is in latching engagement with the second support structure. The latch means further includes retainer means, releasably connected to the slide member, for releasably retaining the latch member with the slide member so that the latch member can be disengaged from the first support structure by releasing the retainer means from the slide member and relieving the biasing means from biasing the latch member.

By the method of the present invention a pipe string disposed in a well can be tested through steps including reciprocating the pipe string to open and close a valve disposed in the pipe string; applying a pressure to the pipe string when the valve is closed to determine if the pipe string leaks; moving the pipe string to place the valve in an open position; and exerting a force on a slide member disposed adjacent the valve so that the slide member moves locking shoulders associated therewith into latching engagement with the valve when the valve is in the open position, whereby the valve is locked open. In the preferred embodiment the step of exerting a force is implemented by pressurising a selectable one of a fluid within the annulus and a fluid within the pipe string for creating a force in excess of a predetermined holding force acting on the slide member.

In order that the invention may be more fully understood, one preferred embodiment thereof will now be described with reference to the accompanying drawings, wherein:

FIGS. 1A and 1B are a partial sectional elevational view of a preferred embodiment of the present invention including a valve disposed in a closed position.

FIGS. 2A and 2B are a partial sectional elevational view of the preferred embodiment shown in FIGS. 1A and 1B with the valve shown in an open position and a latching mechanism shown in an unlatched position.

FIGS. 3A and 3B are a partial sectional elevational view of the preferred embodiment with the valve shown in the open position and the latching mechanism shown in a latched position, whereby the valve is locked open.

The preferred embodiment of the present invention will be described initially with reference to FIGS. 1A-1B. FIGS. 2A-2B and FIGS. 3A-3B will subsequently be referred to and described with reference primarily to the operation of the present invention; however, the parts shown therein are the same as those shown in FIGS. 1A-1B as indicated by the like reference numerals, although with relative position changes as shown.

The present invention will be described with reference to a reciprocating ball valve tubing tester tool 2; however, aspects of the present invention are contemplated as having utility with other types of tools having reciprocating, or axially or telescopingly movable, structures that need to be locked in desired positions. Thus, broadly the present invention comprises two support structures, connected in relative axial sliding cooperation with each other so that the structures are reciprocable between two working positions wherein the support structures are in two different relative positions, and latch means, slidably retained on the two support structures, for latching the support structure together so that further relative axial movement therebetween is prevented when the latch means is axially moved into latching engagement with both of the support structures.

For the specific embodiment shown in FIGS. 1A-1B, the two support structures define a housing of a valve 4 of the tubing tester tool 2, which tool 2 also includes a latch mechanism 6 defining the preferred embodiment of the aforementioned latch means. One support structure of the housing of the valve 4 includes an outer valve housing portion 8, and the other support structure includes an inner valve housing portion 10.

The outer valve housing portion 8 includes an upper adapter 12 having an internally threaded surface 14 for connecting with a pipe string in which the preferred embodiment of the present

invention is contemplated to be used. The adapter 12 also includes an inner surface 16 along which a portion of the inner valve housing portion 10 is slidably disposed and in which a suitable sealing member 18 is disposed. The adapter 12 has a threaded external surface 20 to which an outer valve casing 22 is threadedly connected.

The outer valve casing 22, which is another part of the outer valve housing portion 8, is a cylindrical sleeve having an internally threaded end surface 24 for threadedly engaging with the surface 20 and also having a threaded end surface 26 for threadedly engaging with a threaded surface 28 of a locking dog adapter 30 forming another part of the outer valve housing portion 8.

The locking dog adapter 30 has a cylindrical exterior surface 32 in which an indentation 34 is formed. The indentation 34 of the preferred embodiment is a circumferential groove defined by opposing annular surfaces 36, 38 separated by a circumferential surface 40 radially inwardly offset from the surface 32. The surface 38 defines an engagement shoulder for engaging with the latching mechanism 6 as subsequently described hereinbelow.

Formed between the outer surface 32 and an inner surface 42 of the locking dog adapter 30 are one or more holes 44 for receiving one or more frangible members, such as shear pins, by which the tester valve 4 can be preset in a selectable position.

At the lower end (as viewed in the drawings) of the inner surface 42 of the locking dog adapter 30, there are defined a plurality of splines 46 for mating engagement with complementally formed splines 48 on the inner valve housing portion 10 whereby rotary motion imparted to one of the housing portions is coupled to the other housing portion.

Retained in fixed position within the outer valve housing portion 8 is an actuating arm 50 having a lug 52 extending radially inwardly therefrom for engaging a valve member subsequently described. The actuating arm 50 extends axially between a notch surface 54 of the adapter 12 and a notch surface 56 of the adapter 30 and is disposed radially adjacent an inner surface 58 of the outer valve casing 22.

The inner valve housing portion 10 includes a positioning or guide mandrel and upper valve seat carrier element 60 having offset outer surfaces 62, 64 radially separated by an annular surface 66 which abuts an end surface 68 of the adapter 12 when the tester valve 4 is in an open position as shown in FIGS. 2A-2B, for example. The surface 62 is disposed adjacent the surface 16 of the adapter 12 for relative sliding movement therealong. The member 60 also has a recessed inner surface 70 at its lower end for receiving an upper valve seat 72

forming another part of the inner valve housing portion 10.

Connected to the element 60 by means of a suitable clamping element 74 is a lower valve seat carrier 76 having a recessed inner surface 78 adjacent which a lower valve seat 80 is disposed. The lower valve seat carrier 76 has an annular end surface 79 which abuts an annular end surface 81 of the adapter 30 to prevent further outer telescoping movement between the housing portions 8, 10 when the valve 4 is in its closed position as shown in FIG. 1A. The lower valve seat carrier 76 also has a threaded inner surface 82 threadedly connected to a moving mandrel 84 including an upper portion 86, having a threaded outer surface 88 connected with the surface 82, and a lower portion 90.

The upper portion 86 is a substantially cylindrical sleeve having an outer surface 92 in which two indentations 94, 96 are formed for receiving the ends of one or more shear pins disposed through the one or more holes 44 formed through the locking dog adapter 30. The indentations 94, 96 are circumferential grooves in the preferred embodiment spaced a predetermined distance apart so that the valve 4 can be preset in either a closed position (via indentation 94) or an open position (via indentation 96). The outer surface 92 of the upper portion 86 also includes the aforementioned splines 48. The lower end of the upper portion 86 has an externally threaded surface 98 for threadedly engaging with a threaded interior surface 100 of the lower portion 90.

The lower portion 90 has an exterior surface 102 radially outwardly offset from another exterior surface 104. The separation between the surfaces 102, 104 is defined by an annular surface 106 defining another engagement shoulder for engaging with the latching mechanism 6. The surface 106 faces in an opposite direction (namely downwardly as viewed in the drawings) relative to the surface 38 (which is upwardly facing as viewed in the drawings) defining the first-mentioned engagement shoulder. The surfaces 38, 106 are spaced by a distance which is variable between the maximum distance, depicted in FIG. 1B, when the valve is fully closed and the lesser, minimum distance, depicted in FIGS. 2B and 3B, when the valve is fully open. The surfaces 104, 106 can be said to define an indentation for defining the engagement shoulder.

Defined in the exterior surface 102 is an indentation 108 specifically defined in the preferred embodiment as a circumferential groove for receiving one or more shear pins 110, which pins are a part of the preferred embodiment of the latch mechanism 6.

Formed through the side wall of the lower portion 90 are one or more ports 112 by which fluid

and pressure communication occurs between the interior and exterior of the lower portion 90. As illustrated in the preferred embodiment, the ports are angularly disposed and intersect at the adjoining corner of the surfaces 104, 106.

Formed at the lower exterior end of the lower portion 90 is a threaded surface 114 for threadedly engaging a lower adapter 116 forming another part of the inner valve housing portion 10 of the preferred embodiment. The adapter 116 has a threaded end 118 for coupling with the pipe string or a packer or other element of a type as known to the art.

Each of the aforementioned elements of the outer valve housing portions 8, 10 has a central axial opening defined therethrough so that the telescopically associated housing portions 8, 10 have a central axial flow passage 120 defined throughout the length thereof.

In addition to the housing portions 8, 10, the valve 4 of the preferred embodiment includes a rotatable, reciprocable valve member 122 having a spherical shape in which an eccentric hole 124 is defined for receiving the lug 52 of the actuating arm 50. As shown in FIG. 2A, the valve member 122 has a bore 126 defined therethrough for aligning with the passage 120 when the valve member 122 is moved to the open position depicted in FIGS. 2A-2B and 3A-3B. When the valve member 122 is in the closed position depicted in FIGS. 1A-1B, the closed side wall of the valve member 122 is sealingly seated between the valve seats 72, 80 to block the passage 120, thereby closing the valve 4 to through fluid flow. Because the valve member 122 is retained between the valve seats 72, 80, it moves with the inner valve housing portion 10 relative to the outer valve housing portion 8.

The preferred embodiment of the latching mechanism 6, shown in FIGS. 1A-1B and 2A-2B in its unlatched position whereby the valve 4 can be opened and closed through reciprocating action between the outer and inner housing portions 8, 10 and shown in its latched position in FIGS. 3A-3B whereby the valve 4 is locked in its open position, includes a latch member 128, biasing means 130, a slide member 132, retainer means 134, and holding means including the one or more shear pins 110 and a shear pin retaining sleeve 136.

The preferred embodiment of the latch member 128 includes a split-ring locking dog which in its unlatched position rides so that an inner surface 138 thereof rides adjacent the exterior surface 32 of the locking dog adapter 30. Extending radially outwardly from the surface 138 are end surfaces 140, 142 which are spaced a distance less than the separation of the surfaces 36, 38 of the indentation 34 so that the latch member 128 will be received in the indentation 34 when the latching mechanism 6

is moved to its latched position. When the latch member 128 is so received within the indentation 34, the surface 142 acts as an engagement shoulder for engaging the engagement shoulder defined by the surface 38.

To bias or urge the latch member 128 into the indentation 34, the latch mechanism 6 includes the biasing means 130 which in the preferred embodiment includes a suitable compressive member, such as a ratcheting spring or an O-ring. Thus, when the latch member 128 is moved over the indentation 34 as subsequently described, the natural biasing of the member 130 biases the latch member 128 into latching engagement within the indentation 34.

Movement of the latch member 128 into overlying relationship with the indentation 34 occurs through movement of the slide member 132, which is responsive to a selectable one of a pressure applied through the pipe string communicated through one or more of the ports 112 or a pressure applied through the annulus or space defined between the tool 2 and the well in which it is disposed. The slide member 132 includes an upper annular surface 144 defining an abutment shoulder or engagement means for engaging the surface 142 of the latch member 128. Extending downwardly from the surface 144 is an axially extending cylindrical interior surface 146 disposed adjacent portions of both housing portions 8, 10 as shown in the drawings. Extending radially inwardly from the lower end of the interior surface 146 is an inner annular surface 148 defining engagement means for engaging the surface 106 of the inner valve housing portion 10. The surface 148 also defines means for receiving an axially acting pressure, communicated through the ports 112 from within the tool 2 and the pipe string to which it is connected, for moving the latching mechanism 6. Extending axially from the surface 148 in radially inwardly offset relationship to the interior surface 146 is an interior surface 150 having a sealing member 152 disposed therein. The surface 150 is disposed in sliding relationship along the surface 104 of the lower portion 90 of the moving mandrel of the inner valve housing portion 10. Extending radially outwardly from the surface 150 at the lower end of the slide member 132 is an outer annular surface 154 disposed for receiving a pressurized fluid communicated through the annulus. The surface 154 is spaced from an annular end surface 155 of the adapter 116 so that a gap is defined therebetween to permit movement of the slide member 132 towards the adapter 116 as subsequently described. The surfaces 148, 150, 154 define a rim portion of the slide member 132, which rim portion extends radially inwardly in overlapping relationship with the surface 106 so that the

surfaces 106, 148 engage when the pressure acting on the surface 154 is sufficiently large to move the slide member 132 upwardly as viewed in the drawings. When the surfaces 106, 148 engage, the latch member 128 is disposed over the indentation 34 and thus enters the indentation 34 in response to the biasing of the biasing means 130. So that this is achieved, the axial length of the interior surface 146 is such that it spaces the surface 148 of the slide member 132 and the surface 142 of the latch member 128 a distance equal to the aforementioned minimum spacing between the engagement surfaces 38, 106 of the valve 4, which minimum spacing occurs in the preferred embodiment only when the valve 4 is placed in its fully open position. For this construction of the preferred embodiment, the latching mechanism 6 can thus be operated to latch the inner and outer valve housing portions 8, 10 only when the housing portions 8, 10 are in the relative position placing the valve member 122 in its fully open position.

The slide member 132 also has an axially extending exterior surface 156 having an axially extending recessed portion 158. Extending between areas of the recessed surface 158 and the interior surface 146 are one or more holes 160 for receiving the one or more shear pins 110. When the slide member 132 is in the unlatched position as shown in FIGS. 1A-1B and 2A-2B, the holes 160 are aligned with the holes 108 of the lower portion 90 so that the shear pins can be received therebetween to hold the latching mechanism 6 in its unlatched position.

Extending axially from the outer edge of the annular surface 144 to the recessed surface 158 is a threaded surface 162 for threadedly engaging with the retainer means 134.

In the preferred embodiment the retainer means 134 is a cap having an outer annular surface 164 and an inner annular surface 166. The inner annular surface 166 is spaced from the annular surface 144 of the slide member 132 sufficiently to define a space for holding the latch member 128. When the latching mechanism 6 is in its latched position, the retainer means 134 can be unthreaded from its connection with the slide member 132 so that this is the only disassembly required to obtain access to the latch member 128 and the biasing means 130 for unlatching the mechanism when the tool 2 is retrieved to the surface. Once the retainer means 134 is unthreaded from its connection with the slide member 132, it is moved upwardly through a sufficient distance provided by constructing the tool 2 so that it has an appropriate spacing between a surface 168, extending radially outwardly from the surface 32 of the locking dog adapter 30, and the surface 164 when the latching mechanism 6 is in its latched

position.

In addition to retaining the latch member 128 adjacent and in movable relationship with the slide member 132, the retainer means 134 also retains the shear pin retaining sleeve 136 within the recessed portion defined by the surface 158 of the slide member 132. When the retainer means 134 is released from the slide member 132 so that the latch member 128 can be disengaged, the shear pin retaining sleeve 136 can also be moved upwardly to uncover the holes 160 whereby new shear pins 110 can be installed.

In the preferred embodiment, the shear pins 110 define a specific type of frangible means for holding the slide member 132 with a predetermined holding force in a fixed position relative to at least one of the housing portions 8, 10 until the frangible means is broken in response to a pressure exceeding a predetermined magnitude such as could be exerted by a pressurized fluid communicated to one of the surfaces 148, 154 of the slide member 132. To retain and protect the shear pins 110, the shear pin retaining sleeve 136 is disposed in overlying relation to the shear pins 110 and the shear pin receiving holes 160 as shown in the drawings.

The preferred embodiment reciprocating ball valve tubing tester tool 2 is used, for example, to pressure test the pipe string in which it is connected as many times as desired before a squeeze-cementing or treating job. This permits the operator to locate leaks in the pipe string while the leaks are near the surface. To perform such pressure testing, for example, the valve 4 is opened or closed by compression or tension, respectively, applied to the tool 2 by movement of the pipe string. Alternate compression and tension is applied, whereby alternate opening and closing is achieved, by reciprocating the pipe string. When running in the hole, for example, the force of pushing the pipe string downward can put the tool 2 into compression and the ball valve will open to a position such as is shown in FIGS. 2A-2B. In moving to this position, the inner and outer valve housing portions 8, 10 exhibit relative motion so that the lug 52 and valve member 122 interact to rotate the valve member 122 into the position shown in FIG. 2A. This is the fully open position for the valve member 122; however, despite being in this fully open position, wherein the valve housing portions 8, 10 are in their fully compressed or inwardly telescoped relative position, the latching mechanism 6 has not been activated by this movement. Because the latching mechanism 6 has not latched, the valve member 122 can be repeatedly opened and closed to repeatedly perform the pressure testing. To close the valve member from the position shown in FIGS. 2A-2B, tension is pulled on the

pipe string to return the valve member 122 to the closed position shown in FIGS. 1A-1B. During such unlatched movement, the slide member 132 is held fixed relative to the inner valve housing portion 10 by means of the predetermined holding force exerted by the one or more shear pins 110.

When the valve member 122 is in its closed position, pressure is applied to the pipe string to determine if any leakage occurs. This step is performed in a manner known to the art.

Once the tubing tester tool 2 has been used for its purpose of testing the pipe string, and when the pipe string has been lowered into the well to the desired depth, a packer of a known test is set in a manner as known to the art to seal the annulus so that fluid flow therethrough is blocked. Such a packer is connected in a known manner below the tool 2. When the packer has been set, the weight of the pipe string can be allowed to compress the tool 2 so that it is moved into its open position as shown in FIGS. 2A-2B and 3A-3B. With the packer set, it is normal procedure to apply a pressure to the annulus defined between the pipe string and the well to test the packer seal. When this pressure is applied, it simultaneously acts on the surfaces 154, 164 of the latching mechanism 6. Because the surface 154 has a greater cross-sectional area than the surface 164, the net force exerted by this pressure will be in an axially upward direction as viewed in the drawings. When this net force exceeds the holding force established by any shear pins 110 which are used (and any counterforce exerted by an internal pressure through the ports 112), the shear pins 110 are broken and the slide member 132 is moved upwardly until the surface 148 engages the surface 106 and the latch member 128 enters the indentation 34 whereupon the surface 142 engages the surface 38. Through these engagements of the surfaces 106, 148 and 38 and 142, the inner and outer valve housing portions 8, 10 are fixed in their relative valve-open position so that no further axial movement therebetween can occur. In the preferred embodiment, this locks the valve in the open position. By locking the valve member 122 in its open position, no further control of fluid flow can be achieved with the tool 2 until it is retrieved to the surface and the latching mechanism 6 is released by simply disconnecting just the cap of the retainer means 134 to obtain access to the latch member 128. That is, the latching mechanism 6, and the locking shoulders thereof, can be released without disassembling any part of the valve itself. Locking the valve member 122 in the open position also allows fluid trapped inside the pipe string to drain out while the string is being retrieved from the hole.

An alternative to the use of the annular pressure to break the hold of the shear pins 110 is the

use of pressure within the pipe string and the tool 2 as communicated through the ports 112 for axially acting between the surfaces 106, 148. When the internal pressure is sufficient to overcome the holding force of the shear pins 110 (and any external force exerted by an annulus pressure), the slide member 132 is moved downwardly a sufficient amount which is allowed due to the spacing between the surfaces 154, 155 shown in FIG. 1B, for example. Once the shear pins 110 have been broken by the internal pressure, the annular pressure can thereafter act to move the slide member 132 upwardly to achieve the latching as previously described.

As an optional feature of the preferred embodiment, there are included the one or more shear pin holes 44 and the two grooves 94, 96 by which the valve 4 can be held in a preset position until the action imparted by the pipe string breaks the one or more optional shear pins. If a shear pin is used with the groove 94, the valve is preset in a closed position; if it is used with the groove 96, the valve is preset in an open position, which positions are such that sufficient additional relative axial movement between the housing portions 8, 10 is permitted so that the pins can be sheared by such additional movement.

From the foregoing it is apparent that the present invention offers a flexibility of operation in that the ball valve can be positioned in an open or closed position when running downhole by using the optional shear pins disposed through the one or more holes 44. Furthermore, the ball valve can be opened or closed repeatedly without the valve being automatically or inadvertently locked by only the opening and closing movement of the valve. To lock the valve of the present invention, the locking mechanism must be positively acted upon by a suitable force derived from other than just the opening or closing movement of the valve.

Furthermore, the present invention has a simplified construction which permits simplified maintenance. In particular, only one threaded connection needs to be undone to reposition the locking mechanism. Furthermore, no J-slot is used and fewer O-rings than in at least some other existing designs are used. Also, many existing parts previously known can be used. Material and machining costs have been reduced by constructing the preferred embodiment with a shorter length than in an existing tubing tester tool.

Thus, the present invention is well adapted to carry out the objects and attain the ends and advantages mentioned above as well as those inherent therein. While a preferred embodiment of the invention has been described for the purpose of this disclosure, numerous changes in the construction and arrangement of parts and in the per-

formance of steps can be made by those skilled in the art, which changes are encompassed within the spirit of this invention as defined by the appended claims.

Claims

1. A tester tool for controlling fluid flow through a pipe string disposed in a well, comprising: a first valve housing portion (8) having a first engagement shoulder (38) defined therein; a second valve housing portion (10) having a second engagement shoulder (106) defined therein, said second valve housing portion slidably connected with said first valve housing portion; a valve member (122) movably retained within said first and second housing portions; and latch means (6), slidably disposed adjacent said first and second housing portions, for moving, in response to an applied pressure, between an unlatched position, wherein said first and second housing portions can move relative to each other, and a latched position, wherein said first and second housing portions are latched to prevent relative movement, said latch means having third (142) and fourth (148) engagement shoulders defined therein characterised in that said third and fourth engagement shoulders engage respectively said first and second engagement shoulders when said latch means is moved by the applied pressure to said latched position, and said latch means includes: a slide member (132) having a surface (148) defining said fourth engagement shoulder; a locking dog (128) having a surface (142) defining said third engagement shoulder; and retainer means (134) for retaining said locking dog with said slide member so that said locking dog is moved by said slide member.
2. A tester tool according to claim 1, characterised in that said slide member is disposed for receiving, against said surface defining said fourth engagement shoulder (148), a pressurized fluid communicated through said housing portions and in that said slide member further has another surface (154) disposed for receiving thereagainst a pressurized fluid communicated through an annulus defined between said tool and the well.
3. A tester tool according to claim 2, characterised in that said latch means further includes frangible means (110) for holding said slide member in a fixed position relative to one of said housing portions until said frangible means is broken in response to a force ex-

ceeding a predetermined magnitude exerted by a pressurized fluid communicated to one of said surfaces of said slide member.

4. A tester tool according to claim 1,2 or 3, characterised in that: said valve member is movable, in response to relative movement between said housing portions, between a fully closed position, wherein said first and second engagement shoulders are disposed a first distance apart, and a fully open position, wherein said first and second engagement shoulders are disposed a second distance apart which is less than said first distance, when said latch means is in said unlatched position; and said third and fourth engagement shoulders are spaced from each other by a distance equal to said second distance so that said latch means can be moved to said latched position only when said valve member is in said fully open position.
5. A tester tool according to claim 1, characterised in that: said first valve housing portion includes a locking dog adapter (30) having an exterior surface (32) in which a first indentation (34) is formed for defining said first engagement shoulder; said second valve housing portion includes a mandrel (60), telescopically received within said locking dog adapter, having an exterior surface (102, 104) in which a second indentation is formed for defining said second engagement shoulder; and in that said slide member has an interior surface (146) disposed adjacent portions of said exterior surfaces of said first and second valve housing portions, and has at one end a rim portion extending inwardly from said interior surface for defining said fourth engagement shoulder, and at another end an abutment shoulder (164); and in that said locking dog is retained adjacent said abutment shoulder for movement into engagement with said first engagement shoulder within said first indentation when said slide member moves so that said fourth engagement shoulder engages said second engagement shoulder.
6. A tester tool according to claim 5, characterised in that: said rim portion includes an outer annular surface (154) for receiving thereagainst an outer pressure from within an annulus defined between said tool and the well and said rim portion also includes an inner annular surface defining said fourth engagement shoulder; and said mandrel has a port (112) defined therethrough for communicating an inner pressure within said tool with said

formance of steps can be made by those skilled in the art, which changes are encompassed within the spirit of this invention as defined by the appended claims.

Claims

1. A tester tool for controlling fluid flow through a pipe string disposed in a well, comprising: a first valve housing portion (8) having a first engagement shoulder (38) defined therein; a second valve housing portion (10) having a second engagement shoulder (106) defined therein, said second valve housing portion slidably connected with said first valve housing portion; a valve member (122) movably retained within said first and second housing portions; and latch means (6), slidably disposed adjacent said first and second housing portions, for moving, in response to an applied pressure, between an unlatched position, wherein said first and second housing portions can move relative to each other, and a latched position, wherein said first and second housing portions are latched to prevent relative movement, said latch means having third (142) and fourth (148) engagement shoulders defined therein characterised in that said third and fourth engagement shoulders engage respectively said first and second engagement shoulders when said latch means is moved by the applied pressure to said latched position, and said latch means includes: a slide member (132) having a surface (148) defining said fourth engagement shoulder; a locking dog (128) having a surface (142) defining said third engagement shoulder; and retainer means (134) for retaining said locking dog with said slide member so that said locking dog is moved by said slide member.
2. A tester tool according to claim 1, characterised in that said slide member is disposed for receiving, against said surface defining said fourth engagement shoulder (148), a pressurized fluid communicated through said housing portions and in that said slide member further has another surface (154) disposed for receiving thereagainst a pressurized fluid communicated through an annulus defined between said tool and the well.
3. A tester tool according to claim 2, characterised in that said latch means further includes frangible means (110) for holding said slide member in a fixed position relative to one of said housing portions until said frangible means is broken in response to a force ex-

ceeding a predetermined magnitude exerted by a pressurized fluid communicated to one of said surfaces of said slide member.

4. A tester tool according to claim 1, 2 or 3, characterised in that: said valve member is movable, in response to relative movement between said housing portions, between a fully closed position, wherein said first and second engagement shoulders are disposed a first distance apart, and a fully open position, wherein said first and second engagement shoulders are disposed a second distance apart which is less than said first distance, when said latch means is in said unlatched position; and said third and fourth engagement shoulders are spaced from each other by a distance equal to said second distance so that said latch means can be moved to said latched position only when said valve member is in said fully open position.
5. A tester tool according to claim 1, characterised in that: said first valve housing portion includes a locking dog adapter (30) having an exterior surface (32) in which a first indentation (34) is formed for defining said first engagement shoulder; said second valve housing portion includes a mandrel (60), telescopically received within said locking dog adapter, having an exterior surface (102, 104) in which a second indentation is formed for defining said second engagement shoulder; and in that said slide member has an interior surface (146) disposed adjacent portions of said exterior surfaces of said first and second valve housing portions, and has at one end a rim portion extending inwardly from said interior surface for defining said fourth engagement shoulder, and at another end an abutment shoulder (164); and in that said locking dog is retained adjacent said abutment shoulder for movement into engagement with said first engagement shoulder within said first indentation when said slide member moves so that said fourth engagement shoulder engages said second engagement shoulder.
6. A tester tool according to claim 5, characterised in that: said rim portion includes an outer annular surface (154) for receiving thereagainst an outer pressure from within an annulus defined between said tool and the well and said rim portion also includes an inner annular surface defining said fourth engagement shoulder; and said mandrel has a port (112) defined therethrough for communicating an inner pressure within said tool with said

inner annular surface so that said inner pressure acts on said inner annular surface.

7. A tester tool according to claim 5 or 6, characterised in that said latch means further includes holding means (110) for holding said slide member with a predetermined force in a fixed position relative to said mandrel until either said inner pressure or said outer pressure exerts on said slide member a net force greater than said predetermined force. 5
8. A tester tool according to claim 7, characterised in that said holding means includes: a shear pin (110) disposed through said slide member into engagement with said mandrel; and a shear pin retaining sleeve (136) slidably received along an exterior surface of said slide member in overlying relation to said shear pin. 10 15
9. A tester tool according to claim 9, characterised in that said latch means further includes retainer means (134), threadedly connected to said slide member, for releasably retaining said locking dog and said shear pin retaining sleeve adjacent said slide member. 20 25
10. A tester tool according to claim 6, characterised in that said latch means further includes retainer means (134), threadedly connected to said slide member, for releasably retaining said locking dog adjacent said slide member when said retainer means is connected to said slide member so that said locking dog is releasable from said first indentation when said retainer means is disconnected from said slide member, whereby said tool can be reset without other disassembly of said tool. 30 35

Revendications

1. Outil de tester permettant de contrôler le débit traversant une colonne de production disposée dans un puits, comprenant une première partie de corps de soupape (8), dans laquelle est ménagé un premier épaulement de contact (38), une seconde partie de corps de soupape (10), dans laquelle est ménagé un deuxième épaulement de contact (106), cette seconde partie de corps de soupape étant assemblée de manière coulissante à la première partie de corps de soupape, un obturateur (122), retenu à l'intérieur de ces première et seconde parties de corps de façon à pouvoir se déplacer, et des moyens de verrouillage (6) disposés d'une manière coulissante et suivant une position contiguë à ces première et seconde parties de corps et destinés à se déplacer, sous 40 45 50 55

l'action d'une pression appliquée, entre une position déverrouillée, dans laquelle les première et seconde parties de corps peuvent se déplacer l'une par rapport à l'autre, et une position verrouillée dans laquelle ces dernières sont verrouillées de façon à empêcher un mouvement relatif, un troisième épaulement de contact (142) et un quatrième épaulement de contact (148) étant ménagés dans ces moyens de verrouillage, caractérisé en ce que les troisième et quatrième épaulements de contact viennent respectivement au contact des premier et deuxième épaulements de contact lorsque les moyens de verrouillage sont déplacés, par la pression appliquée, jusqu'à la position verrouillée et en ce que ces moyens de verrouillage comprennent une pièce coulissante (132), comportant une surface (148) présentant le quatrième épaulement de contact, un taquet de blocage (128), comportant une surface (142) présentant le troisième épaulement de contact, et des moyens de retenue (134) permettant de retenir ce taquet de blocage sur la pièce coulissante de façon qu'il soit déplacé par cette dernière.

2. Outil de tester suivant la revendication 1, caractérisé en ce que la pièce coulissante est disposée de façon à être soumise, sur ladite surface constituant le quatrième épaulement de contact (148), à l'action d'un fluide sous pression transmis dans les parties de corps et en ce que cette pièce coulissante comporte une autre surface (154) disposée de façon à être soumise à l'action d'un fluide sous pression transmis dans un annulaire délimité entre l'outil et le puits.
3. Outil de tester suivant la revendication 2, caractérisé en ce que les moyens de verrouillage comprennent en outre des moyens sectionnables (110) permettant de maintenir la pièce coulissante dans une position fixe par rapport à l'une des parties de corps jusqu'à ce que ces moyens sectionnables soient rompus sous l'action d'une force, excédant une valeur fixée à l'avance, qui est exercée par un fluide sous pression mis en communication avec l'une desdites surfaces de la pièce coulissante.
4. Outil de tester suivant l'une des revendications 1 à 3, caractérisé en ce que l'obturateur est mobile, sous l'effet d'un déplacement relatif entre les parties de corps, entre une position totalement fermée, dans laquelle les premier et deuxième épaulements de contact sont séparés l'un de l'autre d'une première distance, et une position totalement ouverte, dans laquelle

ces premier et deuxième épaulements de contact sont séparés l'un de l'autre d'une seconde distance, qui est inférieure à la première distance, lorsque les moyens de verrouillage sont dans leur position déverrouillée, et en ce que les troisième et quatrième épaulements de contact sont espacés l'un de l'autre d'une distance égale à la seconde distance, de sorte que les moyens de verrouillage ne peuvent être déplacés jusqu'à leur position verrouillée que lorsque l'obturateur est dans sa position totalement ouverte.

5. Outil de tester suivant la revendication 1, caractérisé en ce que la première partie de corps de soupape comprend un adaptateur de taquet de blocage (30) comportant une surface extérieure (32) dans laquelle une première partie en retrait (34) est ménagée de façon à constituer le premier épaulement de contact, en ce que la seconde partie de corps de soupape comprend un fourreau (90) disposé d'une manière télescopique dans l'adaptateur de taquet de blocage et comportant une surface extérieure (102, 104) dans laquelle une seconde partie en retrait est ménagée de façon à constituer le second épaulement de contact, en ce que la pièce coulissante comporte une surface intérieure (146) disposée d'une manière contiguë à des sections des surfaces extérieures des première et seconde parties de corps de soupape et comporte, à l'une de ses extrémités, un rebord s'étendant vers l'intérieur à partir de la surface intérieure de façon à constituer le quatrième épaulement de contact et, à son autre extrémité, un épaulement de butée (164), et en ce que le taquet de blocage est retenu dans une position contiguë à cet épaulement de butée en vue de se déplacer au contact du premier épaulement de contact, situé dans la première partie en retrait, lorsque la pièce coulissante se déplace de façon que le quatrième épaulement de contact vienne au contact du deuxième épaulement de contact.
6. Outil de tester suivant la revendication 5, caractérisé en ce que le rebord comporte une surface annulaire extérieure (154) destinée à être soumise à une pression extérieure provenant de l'intérieur de l'annulaire délimité entre l'outil et le puits et comporte aussi une surface annulaire intérieure constituant le quatrième épaulement de contact et en ce que le fourreau est traversé par un orifice (112) servant à transmettre une pression interne régnant dans l'outil jusque sur ladite surface annulaire intérieure, de telle façon que cette pression intérieure agisse sur cette surface annulaire inté-

rieure.

7. Outil de tester suivant l'une des revendications 5 et 6, caractérisé en ce que les moyens de verrouillage comprennent en outre des moyens de maintien (110) permettant de maintenir la pièce coulissante, sous une force fixée à l'avance, dans une position fixe par rapport au fourreau jusqu'à ce que soit la pression intérieure, soit la pression extérieure exerce sur cette pièce coulissante une force nette supérieure à ladite force fixée à l'avance.
8. Outil de tester suivant la revendication 7, caractérisé en ce que les moyens de maintien comprennent une cheville de cisaillement (110), disposée dans la pièce coulissante de façon à coopérer avec le fourreau, et un fourreau de retenue de cheville de cisaillement (136) logé d'une manière coulissante le long d'une surface extérieure de la pièce coulissante, dans une position située au-dessus de la cheville de cisaillement.
9. Outil de tester suivant la revendication 8, caractérisé en ce que les moyens de verrouillage comprennent en outre un moyen de retenue (134) vissé sur la pièce coulissante et servant à retenir, d'une manière détachable, le taquet de blocage et le fourreau de retenue de cheville de cisaillement dans une position contiguë à cette pièce coulissante.
10. Outil de tester suivant la revendication 6, caractérisé en ce que les moyens de verrouillage comprennent en outre un moyen de retenue (134) vissé sur la pièce coulissante et servant à retenir, d'une manière détachable, le taquet de blocage dans une position contiguë à cette pièce coulissante lorsque ce moyen de retenue est fixé sur cette dernière, de sorte que le taquet de blocage peut être libéré de la première partie en retrait lorsque le moyen de retenue est séparé de la pièce coulissante, ce qui permet de replacer l'outil dans son état initial sans autre démontage de celui-ci.

Patentansprüche

1. Prüfwerkzeug zur Kontrolle des Fluidflusses durch eine Rohrleitung in einem Bohrloch, enthaltend ein erstes Ventilgehäuseteil (8) mit einer daran bestimmten ersten Eingriffsschulter (38), ein zweites Ventilgehäuseteil (10), an dem eine zweite Eingriffsschulter (106) bestimmt und das gleitbeweglich mit dem ersten Ventilgehäuseteil verbunden ist, ein innerhalb der ersten und zweiten Ventilgehäuseteile be-

- weglich gehaltenes Ventilielid (122) und gleitbeweglich an den ersten und zweiten Ventilgehäuseteilen angeordnete Riegelmittel (6), die beim Ansprechen auf einen angelegten Druck zwischen einer entriegelten Stellung, in der die ersten und zweiten Ventilgehäuseteile relativ zueinander bewegbar sind, und einer verriegelten Stellung, in der die ersten und zweiten Ventilgehäuseteile zur Verhinderung ihrer Relativbewegung verriegelt sind, verstellbar sind und dritte und vierte Eingriffsschultern (142 bzw. 148) enthalten, dadurch gekennzeichnet, daß die dritte und vierte Eingriffsschulter mit der ersten bzw. zweiten Eingriffsschulter im Eingriff sind, wenn die Riegelmittel bei Druckbeaufschlagung in die verriegelte Stellung verstellt sind, und daß die Riegelmittel ein Gleitglied (132) mit einer die vierte Eingriffsschulter bestimmenden Fläche (148) enthalten, sowie ein Riegelement (128) mit einer die dritte Eingriffsschulter bestimmenden Fläche und eine Halterung (134) zur Halterung des Riegelementes an dem Gleitglied, so daß das Riegelement mittels des Gleitgliedes verstellbar ist.
2. Prüfwerkzeug nach Anspruch 1, dadurch gekennzeichnet, daß das Gleitglied zur Beaufschlagung der die vierte Eingriffsschulter (148) bestimmenden Fläche mit einem durch die Ventilgehäuseteile geleiteten, unter Druck gesetzten Fluid eingerichtet ist und daß das Gleitglied eine weitere Fläche (154) enthält, die zur Beaufschlagung mit einem durch einen Ringraum zwischen dem Werkzeug und dem Bohrloch geleiteten, unter Druck gesetzten Fluid angeordnet ist.
3. Prüfwerkzeug nach Anspruch 2, dadurch gekennzeichnet, daß die Riegelmittel weiterhin Bruchmittel (110) enthalten, die das Gleitglied in einer festgelegten Stellung zu einem der Ventilgehäuseteile halten bis sie unter einer Kraft oberhalb einer vorgegebenen Größe zerbrechen, die durch ein unter Druck gesetztes Fluid ausgeübt wird, das einer der Flächen des Gleitgliedes zugeleitet wird.
4. Prüfwerkzeug nach Anspruch 1, 2 oder 3, dadurch gekennzeichnet, daß das Ventilielid beim Ansprechen auf die Relativbewegung zwischen den Ventilgehäuseteilen zwischen einer vollständig geschlossenen Stellung, in der die erste und zweite Eingriffsschulter in einem ersten Abstand voneinander angeordnet sind, und einer vollständig geöffneten Stellung verstellbar ist, in der die erste und zweite Eingriffsschulter in einem zweiten Abstand, der geringer als der erste Abstand ist, voneinander angeordnet sind, wenn die Riegelmittel in der entriegelten Stellung sind, und daß die dritte und vierte Eingriffsschulter um einen Abstand voneinander entfernt sind, der gleich dem zweiten Abstand ist, so daß die Riegelmittel nur in der vollständig geöffneten Stellung des Ventilielides in die verriegelte Stellung verstellbar sind.
5. Prüfwerkzeug nach Anspruch 1, dadurch gekennzeichnet, daß das erste Ventilgehäuseteil einen Riegeelementadapter (30) mit einer Außenfläche (32) enthält, in der eine erste Vertiefung (34) ausgebildet ist, welche die erste Eingriffsschulter bestimmt, daß das zweite Ventilgehäuseteil einen in den Riegeelementadapter eingeschobenen Dorn (60) mit einer Außenfläche (102, 104) enthält, in der eine zweite Vertiefung ausgebildet ist, welche die zweite Eingriffsschulter bestimmt, daß das Gleitglied eine Innenfläche (146), die an Teilen der Außenfläche der ersten und zweiten Ventilgehäuseteile angeordnet ist, enthält, sowie an einem Ende ein von der Innenfläche nach Innen verlaufendes und die vierte Eingriffsschulter bestimmendes Randteil und am anderen Ende eine Anschlagschulter (164), und daß das Riegelement an der Anschlagschulter gehalten und in Eingriff mit der ersten Eingriffsschulter in der ersten Vertiefung bewegbar ist, wenn sich das Gleitglied derart bewegt, daß die vierte Eingriffsschulter mit der zweiten Eingriffsschulter im Eingriff ist.
6. Prüfwerkzeug nach Anspruch 5, dadurch gekennzeichnet, daß das Randteil eine äußere Ringfläche (154) zur Beaufschlagung mit einem Außendruck aus einem Ringraum, der zwischen dem Werkzeug und dem Bohrloch bestimmt ist, und eine innere Ringfläche enthält, welche die vierte Eingriffsschulter bestimmt, und daß der Dorn eine durchgehende Öffnung (112) enthält, die einen Innendruck im Werkzeug der inneren Ringfläche derart zuleitet, daß diese mit dem Innendruck beaufschlagt wird.
7. Prüfwerkzeug nach Anspruch 5 oder 6, dadurch gekennzeichnet, daß die Riegelmittel Haltemittel (110) enthalten, die das Gleitglied in einer festgelegten Stellung gegenüber dem Dorn mit einer vorgegebenen Kraft halten bis entweder der Innendruck oder der Außendruck auf das Gleitglied eine resultierende Kraft ausübt, die größer als die vorgegebene Kraft ist.
8. Prüfwerkzeug nach Anspruch 7, dadurch ge-

kennzeichnet, daß die Haltemittel einen Scherstift (110), der sich durch das Gleitglied in Eingriff mit dem Dorn erstreckt, und eine Scherstifthaltebuchse (136) enthalten, die längs der Außenfläche des Gleitgliedes gleitbeweglich in einer den Scherstift überdeckenden Weise aufgenommen ist.

5

9. Prüfwerkzeug nach Anspruch 9, dadurch gekennzeichnet, daß die Riegelmittel weiterhin eine durch Gewinde mit dem Gleitglied verbundene Halterung zur lösbaren Halterung des Riegelementes und der Scherstifthaltebuchse an dem Gleitglied aufweisen.

10

15

10. Prüfwerkzeug nach Anspruch 6, dadurch gekennzeichnet, daß die Riegelmittel weiterhin eine durch Gewinde mit dem Gleitglied verbundene Halterung zur lösbaren Halterung des Riegelementes an dem Gleitglied aufweisen, wenn die Halterung mit dem Gleitglied verbunden ist, derart, daß das Riegelement aus der ersten Vertiefung herauslösbar ist, wenn die Halterung von dem Gleitglied gelöst ist, wodurch das Werkzeug ohne weitere Zerlegung rückstellbar ist.
