

Concentrate composition for polymeric chain extension

Background of the invention

- 5 The invention relates generally to concentrates employed in the formation of step-growth polymers, and in particular, to a chain extension concentrate for step-growth polymers.

Many step-growth polymers, including polyesters, polyamides, polycarbonates and
10 polyurethanes are widely used to make plastic products such as films, bottles, sheets and other molded and extruded products. The mechanical and physical properties of these polymers are highly dependent on their molecular weights.

In a life cycle, these materials may experience a synthesis process, followed by an
15 extrusion step and a final processing step which may be another compounding extrusion operation followed by thermoforming, blow molding or fiber spinning or they can be injection molded in the molten state, with all of these steps occurring under high temperature conditions. In addition, in recent years, increased attention has been focused on improved methods of recycling articles made from these
20 polymers, with regarding resource conservation and environmental protection. The processing steps involved in producing and recycling these polymers also involve high temperatures.

In each of these high temperature steps, particularly during the
25 compounding/processing and reclaiming/recycling process some molecular weight degradation in the polymer occurs. This molecular weight degradation may occur via high temperature hydrolysis, alcoholysis or other depolymerisation mechanisms well known for these polycondensates. It is also well known that degradation of molecular weight negatively affects the mechanical, thermal and
30 rheological properties of materials, thus preventing them from being used in demanding applications or from being recycled in large proportions in their original applications. Today recycled or reprocessed polycondensates with deteriorated weight can only be used in very low proportions in demanding applications or in

larger proportions in less demanding applications. For instance, due to molecular weight degradation, recycled bottle grade polyethylene terephthalate (PET) is mostly employed exclusively in films and other low end applications. Similarly, recycled polycarbonate from compact disk (CD) scrap, mostly goes to low end applications. For these reasons, the current recycling technologies are limited to a narrow range of applications.

Today, there exists a considerable number of processes which are employed to minimize loss in molecular weight and maintain or even increase the molecular weight of the polycondensates for processing or recycling. Most of these routes employ as main processing equipment either extruder, solid state polycondensation reactor or both in sequence or similar equipment designed for melt or high viscosity material processing. As processing aid in any process, chemical reactants known as "chain extenders" are employed. Chain extenders usually are multi functional molecules which "recouple" polycondensate chains that have depolymerized. These chain extenders were added to the extruder or reactor while processing the polymer. Normally chain extenders possess two or more functional groups which can react with chain fragments, caused by depolymerisation, to bridge and couple them. That process can stop decreasing or even increase molecular weight of polycondensates. There are numerous chain extender types, compositions, polycondensate formulations and processing conditions which will be described.

Di- or polyfunctional epoxides, epoxy resins or other chemicals having two or more epoxy groups are examples of chain extending modifiers which have been used to increase the molecular weight of recycled polymers. These di- or polyfunctional epoxides are made of epichlorohydrin and molecules with two or more terminal hydroxyl groups. Examples of such chain extenders include bis-phenol type epoxy compounds, made of bisphenol-A and epichlorohydrin, novolak type epoxy compounds made of carboxylic acids and epichlorohydrin and glycidyl ethers made of aliphatic alcohols and epichlorohydrin. Additionally, various acrylic copolymers have been used as polymer additives to improve melt strength and melt viscosity of polyesters and polycarbonates. These additives generally include

copolymers derived from various epoxy containing compounds and olefins, like ethylene. However, these chain extenders only exhibit moderate success in prohibiting degradation in reprocessed polymers.

- 5 Today two main problems persist with the state of the art-solutions. In order to have efficient chain extension at reasonable residence times either in extrusion or solid state reactor systems, most of known chain extenders require the use of pre-dried polycondensate material, operating at vacuum and varying amounts of catalysts and stabilizers to be employed during processing. Without these features
- 10 the extent of molecular weight increase is limited and the resulting product shows lower molecular weight and less than desired properties.

As the functionality of chain extender increases, so does the number of polycondensate chains that can be coupled onto each chain extender molecule

15 and thus its effectiveness in re-building molecular weight. However it's obvious to see that increasing the functionality of chain extenders also increases degree of branching of the resulting product and the potential onset of gelation. There are negative effects of extensive branching on degree of crystallinity and thus on mechanical properties of semi-crystalline polycondensate, as well as negative

20 implications of the presence of varying amounts of gel in any product. As result of these negative effects there is a limit for the maximum functionality. Effective chain extension currently requires relatively large concentration of lower functionality (< 4 functional groups per chain) chain extenders.

- 25 The relatively high costs associated with these two limitations of the current art render the re-processing or recycling of these polycondensation uneconomical.

One type of chain extender that has been effective in overcoming the problems encountered by the prior art are those based on epoxy-functionalized styrene

30 acrylic copolymers produced from monomers of at least one epoxy-functional acrylic monomer and at least non-functional styrenic and/or acrylate monomer. These chain extenders also exhibit certain disadvantages when introduced directly into a molding apparatus. The chain extenders are difficult to pelletize or otherwise

agglomerate. Furthermore, the epoxy-functionalized styrene acrylic copolymer chain extenders are highly reactive in comparison to prior chain extenders. As a result, with certain applications the epoxy-functional styrene acrylic copolymer chain extenders have a tendency to produce overreaction conditions in the feed or introduction zone of a molding apparatus or extruder. These overreaction conditions are a consequence of the disparity in melting temperature between the epoxy-functional styrene acrylic copolymer chain extenders and the step-growth polymers with which they are employed. The epoxy-functional styrene acrylic copolymer chain extenders have a melting temperature of approximately 50 °C, whereas the typical process temperatures for step-growth polymers can range from approximately 240 °C to 300 °C. Thus, when the epoxy-functional styrene acrylic copolymer chain extenders are introduced directly to the feed zone of a processing apparatus, the chain extender melts and begins to react with step-growth polymer before proper dispersion and homogenization is achieved. When the epoxy-functional styrene acrylic copolymer chain extenders prematurely react, localized areas of overreaction produce gelation which in turn interferes with proper particle formation. The problem of over reaction is especially pronounced when manufacturing particles having a minimal thickness, such as e.g. fibers or films.

Consequently, there exists a need in the industry for a method and a concentrate composition or masterbatch which can effectively deliver and allow proper homogenization of chain extenders within polymers. Also because of some acrylic epoxy-functionalized chain extenders contain components which may cause cancer.

Summary of the invention

Accordingly the present invention is directed to a concentrate composition useful in modifying the molecular weight of a step-growth polymer which concentrate comprises an alkyloxy-functionalized terephthalic acid and at least one carrier resin.

According to a preferred embodiment, a concentrate composition includes at least one alkyloxy-functionalized terephthalic acid and at least one reactive carrier resin.

5 According to another preferred embodiment, a concentrate composition includes at least one alkyloxy-functionalized terephthalic acid and at least one non-reactive carrier resin.

As the chain extender is physically homogeneously dispersed in the carrier, while the concentrate composition is mixed with the polymer, the potential for localized
 10 higher concentrations of chain extender is minimized. Furthermore, when introduced into a molding apparatus, the concentrate composition of the present invention prevents premature reaction of alkyloxy-functionalized terephthalic acid chain extender within the let down polymer by increasing the time required to melt the concentrate, this delayed reaction time permits the chain extender to be fully
 15 dispersed throughout the polymer, resulting in homogeneous chain extension. Depending on the carrier resin the concentrate composition of the invention can be solid or liquid, a solid concentrate composition being preferred.

The present invention is directed to a concentrate composition comprising at least
 20 one terephthalic acid ester of formula (1)

wherein

25 R¹ and R² are the same or different and denote C₁-C₁₀-alkyl, preferably C₁-C₆-alkyl, more preferably C₁-C₄-alkyl, most preferably C₁-C₂-alkyl; and at least one carrier resin.

Examples for compounds of formula (1) are dimethylterephthalat, diethylterephthalat, dipropylterephthalat, dibutylterephthalat, dipentylterephthalat, dihexylterephthalat, diheptylterephthalat, dioctylterephthalat, dinonylterephthalat or didecylterephthalat.

The preferred chain extender is dimethylterephthalat (DMT) of formula (2)

This molecule is manufactured by oxidation of the methyl groups on p-xylene and afterwards oxidation to a carboxylic acid, reaction with methanol gives the methyl ester, dimethyl terephthalate. Another possibility is the oxidation of para-xylene or mixed xylene isomers, followed by esterification. Also a customary process to manufacture dimethyl terephthalate is by esterification of purified terephthalic acid with methanol generated by the catalytic homogeneous oxidation of para-xylene. The most widely used technology is based on paraxylene using oxidation and esterification steps. Para xylene is oxidized in the liquid phase by air in the presence of a cobalt salt catalyst to form an oxidate containing p-toluic acid and monomethyl terephthalate. Esterification is carried out in the presence of methanol to form dimethyl terephthalate.

The at least one carrier resin is either a non reactive resin, a reactive resin or a mixture thereof. Preferably, a non-reactive carrier resin is utilized in the concentrate composition of the present invention as the non reactive carrier resin provides an inert carrier, thereby preventing the chain extender from reacting until the concentrate composition is dispersed within the let down polymer. The chain

extender does not react with the non-reactive carrier resin to cause any appreciable chain extension within the non-reactive carrier resin.

5 The non reactive carrier resin can be polyethylene, polyethylene-norbornene copolymers, polypropylene, polybutylene, polymethyl pentene, polyethylene-vinyl acetate copolymers, polycarbonate (PC), polystyrene (PS), polystyrene block copolymers, polybutadiene, polyisoprene, polyethylene-butylene, polyacrylates, polyvinyl chloride, chlorinated polyethylene, polyvinylidene chloride, polyethylene-acrylate copolymers, acrylnitril-butadiene-styrene-copolymers (ABS), and mixtures
10 thereof. The preferred non-reactive carrier resin is ABS, PS, and polycarbonate.

The reactive carrier resin can be polyethylene terephthalate, polybutylene terephthalate, polyethylene terephthalate glycol, maleic anhydride grafted polyethylene (MAH-g PE) and a mixture thereof.

15

The exact ratio of chain extender to carrier resin in the concentrate composition is application specific, depending upon the activity of the carrier resin and the desired degree of chain extension in final polymeric product. The terephthalic acid ester may be present in the concentrate composition in amounts between
20 approximately 0.01 to 99.9 wt.-%, preferably between approximately 5.0 and 50.5 wt.-%; and most preferably between 10.0 und 25.0 wt.-%, relative to the total weight of the concentrate composition.

Other materials which are substantially chemically inert may be added to the
25 concentrate composition depending upon the desired properties of the polymer. Representative examples of such materials include anti-static agents, foaming agents, flame retardants, color concentrates, anti-oxidants, UV stabilizers, anti-block agents, anti-fog agents, anti-slip agents, anti-microbial agents and slip additives.

30

These other materials can be present in the concentrate composition of the invention in amounts of from 0.001 to 99 %, preferably of from 0.001 to 50 % by weight, relative to the total weight of concentrate composition.

If present, the lower limit of said other materials is expediently 0.01 % by weight.

5 The method by which the concentrate composition is made is not particularly limited and can be accomplished by any known method for dispersive or distributive mixing, preferably by extrusion, e.g. in a twin-screw extruder.

10 Further, the concentrate composition of the present invention can be formed in a variety of geometrical shapes, including, but not limited to pellets, spheres, flakes, agglomerates, prills and the like.

The concentrate composition may be used to impart chain extension properties on any let down polymer with at least one carboxyl reactive group. Representative examples of such polymers include step-growth polycondensates such as
15 polyamides, polyesters and polycarbonates. The polymer can also be an addition polymer such as polyurethanes, polystyrene co-maleic anhydride or polyethylene co-acrylic acid.

For said use the concentrate composition is expediently melt compounded with the
20 let down polymer in any thermoplastic forming apparatus normally employed in the industry and is melted at a temperature appropriate for melting or softening the let down polymer, in accordance with normal molding techniques. The exact concentration of the concentrate composition is dependent upon the desired end characteristic of the let down polymer and is therefore application specific. The
25 amount of the concentrate composition to be added to the let-down polymer may range from 0.1 to 50.0 wt.-%, preferably 1.0 to 30.0 wt.-%, more preferably 5.0 to 25.0 wt.-%, relative to the total weight of the concentrate composition and the let-down polymer. The residence time which the concentrate composition in combination with the let down polymer stays on the extruder can vary between 1 s
30 up to 10000 s, preferably 1 s up to 1000 s, more preferably 10 s up to 600 s, even more preferably 15 s to 100 s, most preferably 20 s to 50 s.

The concentration of the chain extender in the let-down polymer is preferably from 0.01 to 10 wt.%, more preferably from 0.1 to 1 wt.%, even more preferably 0.2 to 0.5 wt%, relative to the total weight of the concentrate composition and the let-down polymer.

5

The concentrate composition of the present invention may be used in the manufacture of various polymeric articles, non limiting examples of which includes, polymeric sheets, films, containers, e.g. bottles, fibers or multidimensional articles comprising polycondensates.

10

The following examples will serve to more fully illustrate the invention.

Percentages are weight percent, unless indicated otherwise.

The measurement of the intrinsic viscosity (I.V.) was used to measure the molecular weight of the chain extended polymer as the intrinsic viscosity is a

15 unique function of the molecular weight of a polymer. The I.V. was detected by using a Davenport viscosimeter for melt viscosity measurements, e.g. for PET, in the molten state extruded through a calibrated die using high pressure nitrogen gas.

20 Examples

Example 1:

Five formulations A – E were extruded in accordance with normal industry procedure using a Leistritz MASS technology (27 mm/ 40D). Therefor a

25 masterbatch containing 10 % of the chain extender in polycarbonate as carrier system was extruded. This masterbatch was incorporated in PET (amounts indicated in Table 1) by extrusion at temperatures between 200 and 300 °C with an average residence time of 35 to 40 s. The intrinsic viscosity (I.V.) was determined relative to neat PET.

30

Table 1:

Sample	Concentration of PET [%]	Concentration of DMT chain extender in final product [%]	Increase of I.V. relative to neat PET [%]
A	100	0	0
B	99.9	0.1	20
C	99.85	0.15	27
D	99.8	0.2	25
E	99.775	0.225	25

The used PET was RAMAPET® R 180 GR BB (Indorama Plastics, 192 000 g/mol).

5

Example 2:

Nine formulations A – I were extruded in accordance with normal industry procedure using a Leistritz MASS technology (27 mm/ 40D). Therefore a masterbatch containing 10 % of the chain extender in polycarbonate as carrier

10 system was prepared. This masterbatch was incorporated in PET (amounts indicated in Table 2) by extrusion at temperatures between 200 and 300 °C. In this trial the residence times of material within the extruder was varied.

Table 2:

Sample	Concentration of PET [%]	Concentration of chain extender in finished product [wt.-%]	Residence time [s]	Increase of I.V. relative to neat PET [%]
A	100	0	35	0
B	100	0	50	0
C	100	0	64	0
D	99.9	0.1	35	13

E	99.9	0.1	50	14
F	99.9	0.1	64	10
G	99.7	0.3	35	25
H	99.7	0.3	50	17
I	99.7	0.3	64	17

The used PET was RAMAPET® R 180 GR BB and the chain extender was DMT.

It is demonstrated that the chain extender works best at shorter residence time
5 with high concentrations in process.

Example 3:

Thirteen formulations A – M were extruded in accordance with normal industry
10 procedure using a Leistritz MASS technology (27 mm/ 40D). Therefor a
masterbatch containing 10 % of the chain extender on different carrier systems
was prepared. This masterbatch was incorporated in PET by extrusion at
temperatures between 200 and 300 °C.

15 Table 3:

Sample	Concentration of PET [%]	Concentration of chain extender in finished product [%]	Carrier resin	Increase of I.V. relative to neat PET [%]
A	100	0	-	0
B	99.9	0.1	PC	20
C	99.8	0.2	PC	27
D	99.9	0.1	PET	19
E	99.8	0.2	PET	21
F	99.9	0.1	PP	13

G	99.8	0.2	PP	17
H	99.9	0.1	MAH-g PE	22
I	99.8	0.2	MAH-g PE	24
J	99.9	0.1	PS	24
K	99.8	0.2	PS	31
L	99.9	0.1	ABS	30
M	99.8	0.2	ABS	31

The used PET was RAMAPET® R 180 GR BB and the chain extender was DMT.

Patent claims

1. A concentrate composition comprising at least one terephthalic acid ester of formula (1)

5

wherein

R^1 and R^2 are the same or different and denote a C_1 - C_{10} -alkyl;

10 and at least one carrier resin.

2. The composition as claimed in claim 1, wherein R^1 and R^2 are the same or different and denote a C_1 - C_2 -alkyl.

15 3. The composition as claimed in claim 1 or 2, wherein R^1 and R^2 are methyl.

4. The composition as claimed in any of the preceding claims, wherein the carrier resin is selected from the group consisting of polyethylene, polyethylene-norbonene copolymers, polypropylene, polybutylene, polymethyl pentene, polyethylene-vinyl acetate copolymers, polycarbonate, polystyrene, polystyrene block copolymers, polybutadiene, polyisoprene, polyethylene-butylene, polyacrylates, polyvinyl chloride, chlorinated polyethylene, polyvinylidene chloride, polyethylene-acrylate copolymers, acrylonitrile-butadiene-styrene-copolymers, and mixtures thereof.

25

5. The composition as claimed in any of the preceding claims, wherein the carrier resin is acrylnitril-butadiene-styrene-copolymer, polystyrene or polycarbonate.

5 6. The composition as claimed in any of claims 1 to 3, wherein the carrier resin is polyethylene terephthalate, polybutylene terephthalate, polyethylene terephthalate glycol, maleic anhydride grafted polyethylene, or a mixture thereof.

7. The composition as claimed in any of the preceding claims, wherein the
10 compound of formula (1) is present in an amount of between 0.01 to 99.9 wt.-%, relative to the total weight of the concentrate composition.

8. The composition as claimed in any of the preceding claims, wherein the
15 compound of formula (1) is present in an amount of between 5.0 and 50.0 wt.-%, relative to the total weight of the concentrate composition.

9. A method for preparing a composition as claimed in any of the preceding claims, wherein the compound of formula (1) and the carrier resin are combined by
20 dispersive or distributive mixing.

10. The use of a composition as claimed in any of the preceding claims as chain extender for step-growth polycondensates.

11. The use as claimed in claim 10, wherein the polycondensates are
25 polyamides, polyesters, polycarbonates, polyurethanes, polystyrene co-maleic anhydride or polyethylene co-acrylic acid.

12. The use as claimed in any of claims 10 or 11 in an amount of from 0.1 to 50 wt.-%, more preferably 1 to 30 wt.-%, most preferably 5 to 25 wt.-%, relative to
30 the total weight of the concentrate composition and the polycondensate.

13. The use as claimed in any of claims 10 to 12, wherein the polycondensates are manufactured into polymeric articles.

14. The use as claimed in any of claims 10 to 13, wherein the polymeric articles are sheets, films, containers or fibers.
