

DESCRIPTION

TITLE OF THE INVENTION:

PATIENT STATUS DETERMINATION DEVICE, PATIENT STATUS
DETERMINATION METHOD AND PROGRAM

5 Technical field

[0001]

The present invention relates to a patient status
determination device and the like.

Background Art

10 [0002]

Conventionally, there have been inventions of
biological information monitors which display real-time
signals being measured and historical information of
measured data to thereby enable checking of the current
15 patient status and easy understanding of what kind of changes
the patient has experienced in the past (for example, see
Patent Document 1).

Prior Art Document

Patent Documents

20 [0003]

Patent Document 1:

Japanese Patent Application Laid-open No. 2013-169438

Summary of the Invention

Problem to be Solved by Invention

25 [0004]

In confirming change in the physical condition of a patient, it has been necessary to choose and decide the current conditions based on waveforms and numerical data and the past conditions based on a plurality kinds of biological information.

[0005]

In particular, various kinds of measuring instruments for measuring biological information continuously and measuring biological information at fixed points have emerged in recent years, so that medical staffs need to make judgement based on many kinds of measurement data methods and measurements, which cannot be said to be easy to handle.

[0006]

In view of the above-described problem, it is an object of the present invention to provide a patient status determination device and the like that enables appropriate determination of the status of a patient based on biological information of the patient.

Means for solving the problem

[0007]

In view of the above problem, a patient status determination device of the present invention includes:

a continuous biological information receiving means for receiving continuous biological information from a status detecting device continuously detecting biological

information on a patient;

a measured biological information receiving means for receiving measured biological information from a measuring device measuring the biological information of the patient;

5 and,

a determining means for determining a status of the patient, based on the continuous biological information and the measured biological information.

[0008]

10 A patient status determination method of the present invention includes:

a continuous biological information receiving step of receiving continuous biological information from a status detecting device continuously detecting biological

15 information on a patient;

a measured biological information receiving step of receiving measured biological information from a measuring device measuring biological information of the patient; and,

20 a determining step of determining a status of the patient, based on the continuous biological information and the measured biological information.

[0009]

A program of the present invention is characterized in that by causing a computer to execute:

25 a continuous biological information receiving function

of receiving continuous biological information from a status detecting device continuously detecting biological information on a patient;

5 a measured biological information receiving function of receiving measured biological information from a measuring device measuring biological information of the patient; and,

10 a determining function of determining a status of the patient, based on the continuous biological information and the measured biological information.

Advantages of the Invention

[0010]

15 According to the present invention, the continuous biological information is received from the state detection device that continuously detects the biological information of the patient while the measured biological information is received from the measuring device that measures the biological information of the patient. Then, based on the continuous biological information and the measured
20 biological information, the state of the patient can be determined. As a result, since the state of the patient is determined from both the continuously acquired biological information and the measured biological information measured by, for example, staff and others, it is possible to
25 appropriately determine the state of the patient in a more

suitable manner compared to the case where the state of the patient is determined based on diverse information.

Brief Description of Drawings

[0011]

5 [FIG. 1] A diagram for explaining the entire system in a present embodiment.

[FIG. 2] A diagram for explaining a patient status display device according to the present embodiment.

10 [FIG. 3] A diagram for explaining a functional configuration of a display terminal and a connection device in the present embodiment.

[FIG. 4] A diagram for explaining continuous biological information in the present embodiment.

15 [FIG. 5] A diagram for explaining measured biological information in the present embodiment.

[FIG. 6] A diagram for explaining an alarm threshold table in the present embodiment.

20 [FIG. 7] A diagram for explaining a functional configuration of an electronic medical record server in the present embodiment.

[FIG. 8] A diagram for explaining the electronic medical record data in the present embodiment.

[FIG. 9] A diagram for explaining the overall flow in this embodiment, focusing on screen transitions.

25 [FIG. 10] A diagram for explaining an operation flow of main

processing in the present embodiment.

[FIG. 11] A diagram for explaining an operation flow of an alarm process in the present embodiment.

5 [FIG. 12] A diagram for explaining an operation flow of a patient status display process in the present embodiment.

[FIG. 13] A diagram for explaining an operation flow of a patient status distinctive display process in the present embodiment.

10 [FIG. 14] A diagram for explaining an operation of a patient status distinctive display in the present embodiment.

[FIG. 15] A diagram for explaining a screen example as an operation example in the present embodiment.

[FIG. 16] A diagram for explaining a screen example as an operation example in the present embodiment.

15 [FIG. 17] A diagram for explaining a screen example as an operation example in the present embodiment.

[FIG. 18] A diagram for explaining an operation flow of an electronic medical record registering process in the present embodiment.

20 [FIG. 19] A diagram for explaining a screen example as an operation example in the present embodiment.

[FIG. 20] A diagram for explaining a screen example as an operation example in the present embodiment.

25 [FIG. 21] A diagram for explaining a screen example as an operation example in the present embodiment.

[FIG. 22] A diagram for explaining a screen example as an operation example in the present embodiment.

[FIG. 23] A diagram for explaining a screen example as an operation example in the present embodiment.

5 [FIG. 24] A diagram for explaining an operation example in the present embodiment.

Mode for Carrying Out the Invention

[0012]

10 Hereinafter, the best mode for carrying out the present invention will be described with reference to the drawings. The following embodiment is an example in which the patient status determination device of the present invention is applied, and it goes without saying that the content of the invention is not limited to the present embodiment.

15 [0013] [1. Entire System]

To being with, the entire system in this embodiment will be described. FIG. 1 is a diagram for explaining the whole of a patient status display system 1 incorporating a patient status determination device.

20 [0014]

First, a patient P lies on a mattress 5 placed on a bed 3. A state detection device 20 is provided in the bed.

[0015]

25 The state detection device 20 is a device capable of continuously acquiring biological information of a patient,

and acquires values such as a patient's body weight, body movement, blood pressure, and blood glucose level, for example. As an example, the state detection device 20 may be provided, as shown in FIG. 1, between the bed 3 and the mattress 5, or a sensor may be attached to the patient to detect a state thereof. Alternatively, the device may be set directly on the bed device (e.g., a load acting on an actuator is used). Then, the state detection device 20 is connected to the patient status display device 10.

[0016]

The patient status display device 10 has a function of a patient status determination device and is connected to the state detection device 20, connected to a measuring device 60, and/or connected to another server device or the like via a network. Further, by placing an authentication card 65 over the patient status display device 10, authentication process (login processing) can be performed.

[0017]

The login process is performed by an authorized person such as a staff (nurse, doctor, assistant staff) and the like. By logging in, the person can check the biological information values and the content of the alarms and register them into the electronic medical record. It is possible to provide a configuration that allows authority setting for each log-in person so as to differentiate the operable range.

[0018]

Connected to the network are, for example a server 30, an electronic medical record server 40, a terminal device 50 and a portable terminal device 55 are connected to the network.

[0019]

The server 30 is a server that provides various services, and may be connected to a LAN in the hospital or facility, or may be provided externally via the internet.

[0020]

The electronic medical record server 40 is a server that stores information of electronic medical records on patients. Usually, this server is connected to the network in the hospital or facility, but for example, an external cloud server may be used.

[0021]

The terminal device 50 is a terminal device allowing connection in a nurse station or a management room and enables a grasp of the state of the patient status display device 10 from a remote place. Further, the portable terminal device 55 can be wirelessly connected to a LAN, for example, so that a nurse, assistant staff and the like can easily check information of the patient status display device 10.

[0022]

The patient condition display device 10 will be

described in detail with reference to FIG. 2. The patient status display device 10 includes a display terminal 1000 and a connection device 2000. The display terminal 1000 is, for example, a tablet type display terminal and displays various types of information and receives inputs of various operations. The display terminal 1000 may be a dedicated terminal as a part of the patient status display device 10, or may be implemented by installing application (program) in a general-purpose tablet terminal.

[0023]

The connection device 2000 is a device for connecting the display terminal 1000 to various devices. That is, this device functions like a hub for various devices. For example, as shown in FIG. 1, connection of this device to the state detection device 20 makes it possible to continuously acquire the biological information of the patient, receive biological information from the measuring device 60 (e.g., a thermometer) and also receive biological information from a device attached to the patient's body (e.g., a wristwatch type wearable measuring device). Further, when the authentication card 65 is made to access a communicator 220, for example, it is also possible to perform an authentication process (e.g., patient authentication and staff authentication). As an authentication method, NFC is used as an example of short-range wireless communication in the

present embodiment, but it is also possible to use other methods such as barcode, infrared, IC tag.

[0024]

Further, a notifying unit 260 is provided so as to be
5 able to give notice when, for example, an error occurs.
Furthermore, the notifying unit is connectable to a server
device and the like via a LAN (LAN may be either a wired LAN
or a wireless LAN). The notifying unit 260 may be configured
to be invisible in the normal condition and lit (displayed)
10 only when giving notice. Further, the notifying unit may be
configured to give notice by sound such as an alarm sound,
warning sound and voice, or by light, instead of display.

[0025]

In this embodiment, the display terminal 1000 is
15 described as being used by being mounted on the connection
device 2000, but the display terminal 1000 and the connection
device 2000 may be used separately. For example, the display
terminal 1000 may be taken out and used in another place,
or the connection device 2000 may be built in the bed device
20 while the display terminal 1000 may be used separately.

[0026] [2. Functional Configuration]

Next, the functional configuration in the present
embodiment will be described with reference to the drawings.
FIG. 3 is the diagram for explaining the functional
25 configurations of the display terminal 1000 and the

connection device 2000 in the patient status display device
10.

[0027] [2.1 Display Terminal]

First, the functional configuration of the display
5 terminal 1000 will be described. The display terminal 1000
includes a control unit 100, a storage unit 110, a device
communicator 150, an operation unit 160, a display unit 170
and a LAN communicator 180.

[0028]

10 The control unit 100 is a functional unit for controlling
the entire display terminal 1000. The control unit 100
realizes various functions by reading and executing various
programs stored in the storage unit 110 and is configured
by, for example, a CPU (Central Process Unit) or the like.

15 [0029]

The storage unit 110 is a functional unit in which
various programs necessary for the operation of the display
terminal 1000 and various data are stored. The storage unit
110 is composed of, for example, a semiconductor memory, an
20 HDD (Hard Disk Drive) or the like.

[0030]

The storage unit 110 stores biological information 112,
personal electronic medical record data 120, an alarm
threshold table 122, and also stores as programs, a main
25 program 132, an alarm program 134, a patient status display

program 136 and an electronic medical record registering program 138.

[0031]

Stored as the biological information 112 are continuous
5 biological information 114 which is biological information
continuously detected from the state detection device 20 and
measured biological information 116 which is received from
the measuring device 60 at an arbitrary point of time. Here,
as the measured biological information, it is also possible
10 to use manual input and/or the values of the continuous
biological information instead, if required.

[0032]

FIG. 4 shows an example of a data structure of the
continuous biological information 114. Stored as the
15 continuous biological information 114 of the present
embodiment are the values of the biological information
detected from the state detection device 20 and state values
of biological information that can be detected from the other
patient.

20 [0033]

That is, the information is stored based on continuously
detectable values. The stored examples include the
measurement date and time (e.g., "2015/05/16 20:00") and
values of certain types of biological information such as
25 the pulse rate (e.g., "126") and the body temperature (e.g.,

"37.2"), the breathing rate (e.g., "15") and SpO2 (e.g., "99"). That is, the continuous biological information 114 can obtain the predetermined measurement values at any time. The continuous biological information 114 may be acquired from the state detection device 20 or may be acquired from detection devices provided in the bed 3. Alternatively, various sensors may be provided on the body of the patient to acquire the information.

[0034]

The thus acquired various types of biological information can be collectively managed as continuous biological information. Various values of biological information are detected as required (e.g., when a body motion detection sensor alone is used, body movement state, sleeping state, patient posture (away from bed, in bed, sitting in bed), pulse rate and respiratory rate are detected as continuous biological information).

[0035]

Stored as the measured biological information 116 is biological information received from external measuring devices such as a thermometer, a blood pressure monitor, a body fat meter and the like. As shown in FIG. 5, examples of the measured biological information 116 of the present embodiment may include the reception date and time (e.g., "2015/05/16 20:00") and values for individual types of

biological information (e.g., "37.2" for "body temperature"). Also, for example, the highest blood pressure (e.g., "159") and the lowest blood pressure (e.g., "98") may be stored.
[0036]

5 The detected continuous biological information 114 and measured biological information 116 may be stored for a predetermined period of time. For example, as to the period for storing data, data for one day or three days may be stored. Further, the continuous biological information 114 and the
10 measured biological information 116 may be stored in the server 30.

[0037]

 The personal electronic medical record data 120 stores electronic patient record data of an individual patient. The
15 collection of the patient's individual electronic medical record data is stored in the electronic medical record server 40. Since the data structure of the personal electronic medical record data 120 is the same as that stored in the electronic medical record server 40, details will be
20 described later. Briefly, other than patient information, continuous biological information, measured biological information and the like at the time of registration are registered.

[0038]

25 Though the present embodiment is described on the

assumption that the electronic medical record is stored in the storage unit 110, data from the electronic medical record server 40 may be directly used. In this case, it is not necessary to store the personal electronic medical record data 120 in the storage unit 110.

[0039]

The alarm threshold table 122 stores alarm thresholds for various biological information values. When the value of the measured (received) biological information exceeds the alarm threshold, notice is given and/or error processing is performed. This alarm threshold may be set in advance or set arbitrarily.

[0040]

FIG. 6 shows an example of the alarm threshold table 122. As shown in FIG. 6, upper and lower alarm thresholds are stored for each type of biological information. In addition, a plurality of alarm thresholds can be stored for different alarm levels. In the present embodiment, two alarm levels, i.e., a caution level and a warning level are stored by the alarm thresholds.

[0041]

For example, as to "pulse" which is one of the biological information, thresholds (threshold values specifying the ranges of caution and warning levels) of the pulse rate as the biological information value are stored. As the upper

limit threshold, "110" is stored for the caution level and "130" is stored for the warning level. On the other hand, as the lower threshold, "60" is stored for the caution level and "30" is stored for the warning level.

5 [0042]

For example, when being equal or higher than 130, or equal to or lower than 30, the pulse rate can be determined to fall in the warning level range. Also, when being "equal to 110 or higher than 110 and lower than 130" or "higher than 10 30 and lower than 60 or equal to 60", the pulse rate can be determined to fall in the caution level range. Each range may also be specified to start beyond the threshold (for example, the warning level range of the pulse may be specified to be higher than 130 or lower than 30).

15 [0043]

Though, in the present embodiment, for description convenience, an example defined with two ranges, i.e., the caution level range and the warning level range is given, it is a matter of course that two or more level ranges may 20 be set up.

[0044]

The patient status distinctive information 124 is information for storing the status of the patient. The patient status distinctive information is used to perform 25 patient status distinctive display, which will be described

later. In the present embodiment, the patient status distinctive information determined based on the biological information of the patient in the interval from logout to the present (interval patient status distinctive information) and the patient status distinctive information determined based on the current biological information of the patient (current patient status distinctive information) are stored.

[0045]

Here, as the patient status distinctive information, "normal", "caution" or "warning" state is stored. Normal refers to a case where the biological information values of the patient fall within the alarm threshold range (a range that is neither the caution level nor the warning level). "Caution" is a case where among the biological information values of the patient, there is a biological information value falling within the threshold range of the caution level. Likewise, "warning" is a case where among the biological information values of the patient, there is a biological information value falling within the threshold range of the warning level.

[0046]

In the present embodiment, the interval patient status distinctive information is determined based on the biological information values from the last logout to the

present. Further, another piece of interval patient status distinctive information may be additionally stored based on the biological information values between the logout at the time before last and the last login time.

5 [0047]

Here, in the present embodiment, the patient status distinctive information changes if one of the biological information values falls within the associated range.

However, the patient status distinctive information may be
10 updated when a plurality of biological information values fall in the caution level or warning level. Further, the patient status distinctive information is not limited single one, the patient status distinctive information may be stored individual biological information or individual
15 predetermined group of biological information. For example, the continuous biological information and the measured biological information are classified into different predetermined groups, so that the patient status distinctive information may be determined based on the individual patient
20 condition and stored separately.

[0048]

The programs stored in the storage unit 110 can be read out by the control unit 100, which realizes various functions. More specifically, reading and execution of the main program
25 132 implements a main function, reading and execution of the

alarm program 134 implements an alarm function, reading and execution of the patient status display program 136 implements a patient status display function, and reading and execution of the electronic medical record registering program 138 implements an electronic medical record registering function.

[0049]

The device communicator 150 is a functional unit for communicating with a device communicator 250 to be described later. Though in description of the present embodiment, communication is performed by USB connection, other versatile connection methods, wireless connection (Bluetooth (registered trademark), wireless LAN, etc.) may be used. Alternatively, a dedicated connection interface may be provided to perform communication.

[0050]

The operation unit 160 is a functional unit that receives operation input from a user, and may be formed of, for example, software keys realized by a touch panel and/or input devices such as a keyboard, a mouse and the like. Also, voice input and other input methods may be employed.

[0051]

The display unit 170 is a functional unit that displays various kinds of information to the user and performs notification processes and is realized by means of, for

example, a liquid crystal display etc. Further, the operation unit 160 and the display unit 170 may be integrally formed of a touch panel.

[0052]

5 The LAN communicator 180 is an interface unit connectable to the LAN, and formed by a NIC for connecting to Ethernet (registered trademark) or the like. The LAN communicator 180 may be provided in the connection device 2000. In this case, the data to be transmitted is once sent
10 to the connection device 2000 via the device communicator 150 (250), and then transmitted to the network. Note that connection to the LAN may be implemented by either wired or wireless one.

[0053] [2. 2. Connection Device]

15 Subsequently, the functional configuration of the connection device 2000 will be described. The connection device 2000 includes a control unit 200, a storage unit 210, the communicator 220, an interface unit 230, the device communicator 250 and the notifying unit 260.

20 [0054]

 The control unit 200 is a functional unit for controlling the connection device 2000 as a whole. The control unit 200 realizes various functions by reading out and executing various programs stored in the storage unit 210 and is
25 configured of, for example, a CPU (Central Process Unit) and

the like.

[0055]

The storage unit 210 is a functional unit in which various programs necessary for the operation of the connection device 2000 and various data are stored. The
5 storage unit 210 is composed of, for example, a semiconductor memory, an HDD (Hard Disk Drive) or the like.

[0056]

The communicator 220 is a functional unit for
10 communicating with other devices and an authentication card. For example, the communicator can perform NFC (Near Field Communication) communication as short-range communication. In the case of NFC communication, authentication is performed by placing the authentication card 65 thereover. Further,
15 when the measuring device 60 has the NFC communication function, by placing the measuring device 60, it is possible to receive the biological information via the connection device 2000. As the measuring device 60, for example a device such as a smartphone may be used, or a wearable terminal device
20 such as a watch may be used.

[0057]

As a matter of course, as the communicator 220, any method such as Bluetooth (registered trademark), TransferJet (registered trademark), ZigBee (registered trademark) and
25 RFID may be adopted. Further, a LAN (wireless LAN, wired LAN)

or the like may be used.

[0058]

The interface unit 230 is a functional unit for communicating with other devices. For example, this unit is provided as a functional unit for connection with the state
5 detection device 20. The interface for connection may be implemented by a dedicated interface or may be realized by a general-purpose interface such as USB or RS-232C.

[0059]

10 The device communicator 250 is a functional unit for enabling communication between the display terminal 1000 and the connection device 2000 via the aforementioned device communicator 150. Connection for this may be implemented using, for example USB or the like or via a LAN. In the present
15 embodiment, for explanation convenience, the functions of the communicators are described separately from one another, but may be integrated into one. That is, when all the communications are performed by Bluetooth, the device communicator 250, the communicator 220 and the interface unit
20 230 can be configured by one functional unit.

[0060]

The notifying unit 260 is a functional unit that operates when the connection device 2000 implements a notification process. For example, if an error display needs to be done,
25 this is done. As a means for notifying, any method such as

sound, light, display, vibration, etc. can be considered.

[0061] [2.3 Electronic Medical Record Server]

Next, the functional configuration of the electronic medical record server 40 will be described with reference to FIG. 7. The electronic medical record server 40 includes a control unit 400, a communicator 410 and a storage unit 450.

[0062]

The control unit 400 is a functional unit for controlling the electronic medical record server 40 as a whole. The control unit 400 realizes various functions by reading out and executing various programs stored in the storage unit 450, and is configured of, for example, a CPU (Central Process Unit) and the like.

[0063]

The communicator 410 is an interface unit for connection to a network. This unit is composed of, for example, an NIC that can be connected to Ethernet. The communicator 410 enables communication with other devices through itself.

[0064]

The storage unit 450 is a functional unit in which various programs necessary for the operation of the electronic medical record server 40 and various data are stored. The storage unit 450 is configured of, for example, a semiconductor memory, an HDD (Hard Disk Drive) or the like.

[0065]

Stored in the storage unit 450 is electronic medical record data 452. FIG. 8 shows an example of electronic medical record data. The electronic medical record data stores patient information for each patient, including basic information such as patient number and name, and medical care information such as a doctor in charge as in R100 of FIG. 8 and caution information (R102) indicating a patient's condition and the like, a pictogram, and measured biological information (biological information values) (R104).

[0066]

Here, the caution information is information for making the medical staff, assistant staff, etc., and experts aware the conditions of the patient. For example, warning information (prohibition of nose blowing etc.) and risk assessments such as bed sore assessment, risk-of-falling assessment etc., are recorded. These information may be controlled by flags or may be managed by text, icons, pictures and others.

[0067]

In addition, pictogram information may be stored for easier understanding. Pictograms are based on information on everyday life. Display of the pictograms enables a person who happens to pass by to take care of the patient, thereby providing safety and security. In this way, the pictogram

information conveys information on the conditions of the patient to be notified to many people, whereas the caution information conveys information on the status of the patient to the experts.

5 [0068] [3. Screen (State) Transition Diagram]

Next, the flow of the entire system in the present embodiment will be described using the screen transition diagram (state transition diagram) in FIG. 9.

[0069]

10 First, when the system is activated, it is determined whether an alarm state is taking place, that is, whether any of biological information values exceeds the alarm threshold (or is less than the alarm threshold). Then, an alarm screen (P100) is displayed as necessary. This alarm screen can tell
15 occurrence of a problem, but will not display the content of the error until the user logs in. This feature makes it possible to prevent display of the content of an error which should not be notified to the patient and family.

[0070]

20 Though the alarm screen is displayed when the system is started such as when the power is turned on, occurrence of an alarm state may also be checked at any time. So, the current screen may be interrupted and transitioned to the alarm screen once an alarm state takes place.

25 [0071]

Subsequently, a patient status display screen (P102) is displayed as the main state. In this screen, name plate information, pictogram information, caution information, error status and the like are displayed as basic information of the patient. Thereby, it is possible to display necessary information to medical staff such as nurses and doctors, caregivers and families who are taking care of the patient. [0072]

The patient status display screen (P102) does not display detailed information because it can be seen by the patient, family members and third parties who visited the hospital. The patient status display screen can be switched into the login screen (P104) as necessary, by executing authentication processing and by performing log-in processing. From the login screen, it is possible to transition to various screens. For example, the login screen can be switched to a patient information display screen (P114) capable of displaying patient information, a biological information display screen (P106) displaying biological information values, a graph display screen (P108) capable of displaying the history of biological information values and a vital registration screen (P110) for registering the biological information values in the electronic medical record.

[0073]

Furthermore, it is possible to switch to an alarm setting/history screen (P116) for setting conditions to actuate an alarm state and a reminder screen (P112) which can be set for the things to do next (e.g., instruction of medication etc.).

[0074]

As described above, according to the present embodiment, it is possible to display information relating to the patient in a unified manner and display appropriate information by switching the screens as necessary. Further, by collectively obtaining information from a plurality of measuring devices in a unified manner and registering them in the electronic medical record, it is possible to manage the information on the patient in a unified manner.

[0075] [4. Explanation of Individual Processes]

Next, each process in the present embodiment will be described with reference to the drawings.

[0076] [4.1 Main Process]

The main process in this embodiment will be described with reference to FIG. 10. The main process is a process realized by the control unit 100 which reads out and executes the main program 132 stored in the storage unit 110.

[0077]

First, it is determined whether or not an alarm state is occurring (Step S102). Specifically, each vital value is

compared with its alarm threshold so as to determine whether the vital value exceeds the alarm threshold or is less than the alarm threshold and determine whether or not to issue an alarm. If it is necessary to issue the alarm, an alarm process is effected (Step S102; Yes -> Step S104 in FIG. 10).
[0078]

It should be noted that whether or not each vital exceeds the alarm threshold depends on the type of biological information. Besides, there are cases in which judgment is made on both the judgment criteria (that is, it is determined whether or not the vital value is within a predetermined range).
[0079]

Subsequently, the patient status is determined, so that a patient status display process for displaying the patient status based on the determined result is executed (Step S106 in FIG. 11). Here, if login authentication is not performed (or login has failed), the control is repeatedly executed from Step S102 (Step S108; No -> Step S102).

[0080]

Here, when the login authentication is performed correctly (Step S108; Yes), a staff screen as the login screen is displayed (Step S110). The staff screen is a screen on which various processes can be selected. Here, when a staff process is selected (Step S112: Yes), processing is executed

according to the selected staff process (Step S114). Each of the processes executed here will be described later.

[0081]

When logout is not performed regardless of the state
5 that the staff process is not selected (Step S112; No) or
a staff process has been executed, the login state continues
and the same control is repeated (Step S116; No -> Step S110).
On the other hand, when logout is performed, the user logs
out and the process from Step S102 is repeatedly executed
10 (Step S116; Yes -> Step S102).

[0082]

Here, the selected staff process is one of processes
corresponding to P106 to P116 illustrated in the screen
transition diagram of FIG. 9. These processes will be
15 described using processing flows and/or screen examples.

[0083] [4.2 Alarm Process]

Alarm processing will be described with reference to
FIG. 11. Alarm processing is a process corresponding to P100
in FIG. 9 (Step S104 in FIG. 10) and is implemented by the
20 control unit 100 which reads out and executes the alarm
program 134 stored in the storage unit 110.

[0084]

First, it is determined whether there is a device
connection error (Step S202). Here, if there is a device
25 connection error, a device error output is displayed (Step

S202; Yes -> Step S204).

[0085]

Then, it is determined whether there is biological information being in an alarm state (Step S202; No -> Step S206, or Step S204 -> Step S206). Specifically, each biological information value is compared with its alarm threshold so as to determine whether or not the value is in an alarm state. If there is a biological information value that produces the alarm state (Step S206; Yes), a notification process is executed (Step S208).

[0086]

As an example of the notification process, a notification is given by the notifying unit 260, or an alarm screen is displayed on the display unit 170. At this time, detailed information should be displayed only after logging in (only after being authenticated).

[0087]

Although the alarm process is described as being executed at Step S104 in FIG. 10, it is possible to configure the system such that the alarm process may be performed as an interrupt process by checking the system at intervals of a predetermined period.

[0088]

In this way, if there is biological information that produces the alarm state, it is possible to raise the alarm

by performing the notification process. In addition, if there occurs the device connection error, the device error may be output as one of alarm processing. It should be noted that the device connection error may be output by another method, or may be made so as not to be output.

[0089]

Further, the details of the alarm may be given to the terminal device 50, the portable terminal device 55 and the like. In this case, the notice destination and/or the notice content may be changed between the caution level and the warning level, for example.

[0090]

For example, a table for storing how a notification should be made in correspondence with the state of the patient and the type of biological information is stored for each patient. At this time, as the notification settings, "OFF" is stored for no notifying, "caution" is stored to give notice when noticing level is set at the caution level, and "warning" is stored to give notice when the notice level is set at the warning level. Also, for some kind of item, "ON" or "OFF" may be simply set depending on, for example, whether or not the patient is leaving the bed or not.

[0091]

Further, the notice destination may be previously determined in association with the notification setting.

For example, suppose that "the portable terminal device of a nurse in charge" and the "PC" in the nurse station etc. are set as the first notice destination, and that in addition to "the portable terminal device of a nurse in charge" and the "PC, "portable terminal device of the doctor in charge" is designated as the second notice destination.

[0092]

In this case, when the notification setting is "ON" or "caution", notice is given to the first notice destination. , When the notification setting is "warning", notice is given to the second report destination. In the present embodiment, "the nurses in charge" and "doctors in charge" are extracted from the electronic medical record. Note that the notice destination information may be set separately from the electronic medical record.

[0093]

In this manner, depending on the content according to the notification setting, notification may be made to the previously set notice destination. Here, in addition to setting notice destinations for every patient, a common notice destination may be set. For example, suppose that a rapid response team is set up as an emergency notice destination for all patients. In this case, it is possible to provide such a configuration that when, for example, a biological information value of the patient exceeds its

emergency threshold, or when a plurality of warning level states take place, a notification is made to the emergency notice destination.

[0094]

5 Here, the notification setting is configured such that a notification is given in the case of a caution level or warning level, which means that a notification is given in excess of each level. For example, when the notification setting is set at a caution level, notification is given to
10 the first notice destination when the associated biological information reaches the caution level, and notification is given to the second notice destination when the warning level is reached. That is, the notification setting of the caution level contains that of the warning level. It is possible to
15 configure the notification setting such that notification is made based on caution level alone.

[0095] [4.3 Patient Status Display Process]

[4.3.1 Processing Flow]

 Patient status display processing will be described
20 with reference to FIG. 12. The patient status display processing is a process corresponding to P102 in FIG. 9 (Step S106 in FIG. 10), and is implemented by the control unit 100 which reads out and runs the patient status display program
136 stored in the storage unit 110.

25 [0096]

First, the personal electronic medical record data 120 is read out (Step S302). Here, it is possible to provide a configuration such that authentication of the patient is performed before reading out the data of the electronic medical record, then the data on the authenticated patient is read out.

[0097]

Next, a name plate region is created from the basic information and the medical information contained in the personal electronic medical record data 120 (Step S304), and a pictogram area is further created from the caution information and the set pictogram (Step S306).

[0098]

Specifically, the name plate region (the region in which name plate information is displayed on the display screen) is created from the basic information containing the name, room number and the name of a doctor in charge, stored in the personal medical record data 120 synchronized with the electronic medical record data 452 of the electronic medical record server 40.

[0099]

Also, based on general caution information for the patient/carer person, stored in the personal electronic medical record data 120, a display of the pictogram is created.

[0100]

Subsequently, a warning region based on the caution information is created (Step S308), and if there is error information, error information is generated (Step S310).

5 Herein, the warning information to be displayed in the warning region is created based on information that alerts the experts such as medical staff and carer. Therefore, the region is created in such a manner that those other than the medical staff, such as the patient and their family members, cannot
10 understand the content just looking the display. In addition, the error information contains information relating to the alarm, but similarly the region is created in such a manner that those other than the medical staff, such as the patient and their family members, cannot understand the content just
15 looking the display.

[0101]

Thus, the patient status display screen is filled with the regions created by the above steps, and displayed (Step S312).

20 [0102] [4.3.2 Patient Status Distinctive Display Process]

Next, patient status distinctive display processing is executed to display the patient status distinctively on the patient status display screen (Step S314). Now, the patient status distinctive display processing will be described with
25 reference to FIG. 13.

[0103]

First, when a logout process is performed (Step S352; Yes), the currently stored patient status information is once cleared (Step S354). Then, the continuous biological
5 information and the measured biological information are received (input) (Step S356).

[0104]

When the continuous biological information or the measured biological information is received, the current
10 patient status (current patient status) is determined (Step S358). Here, the current patient status is determined to be in one of "warning", "caution" and "normal" based on all the received biological information. Specifically, the status is determined to be "caution" if any of biological information
15 values is contained in the caution level defined by alarm thresholds, and to be "warning" if any of biological information values is contained in the warning level defined by alarm thresholds.

[0105]

20 Subsequently, the interval patient status is updated (Steps S362 to S370). More specifically, if the interval patient status is "warning", "warning" is maintained as it is (Step S362; Yes).

[0106]

25 Then, when the interval patient status is other than

"warning" and the current patient status is "warning", the interval patient status is set to "warning" (Step S362; No -> Step S364; Yes -> Step S366). That is, when the interval patient status is "caution" or "normal" and if the current patient status is "warning", the interval patient status is set to "warning".

[0107]

When the interval patient status is "normal" and the current patient status is "caution", the interval patient status is set to "caution" (Step S362; No -> Step S364; No -> Step S368; Yes -> Step S370). That is, when the interval patient status is "normal" and if the current patient status is "caution", the interval patient status is set to "caution". When the interval patient status is "caution" and the current patient status is "normal" or "caution", the state of "caution" is maintained as it is (Step S362; No -> Step S364; No -> Step S368; Yes -> Step S370).

[0108]

When the current patient status remains "normal" and the interval patient status is "normal", the interval patient status remains "normal" as it is (Step S362; No -> Step S364; No -> Step S368; No).

[0109]

In this way, when the patient state is determined to be on a more critical state in the order of "normal" <

"caution" < "warning", the interval patient status is updated to the more critical level. Once the state has reached the more critical level, the level is kept as it is until the status is cleared next (e.g., until the next login timing).

5 [0110]

Then, based on the patient status (the interval patient status and the current patient status), the patient status distinctive display is updated (Step S372). Thus, the staff can easily confirm the current patient status and the worst state from the last logout time to the present.

10

[0111]

Thereafter, until the login process is performed again, the process from Step S356 is repeated (Step S374; No -> Step S356).

15

[0112]

Now, the scheme of the operation of patient status distinctive display will be described with reference to FIG. 14. FIG. 14(a) shows an example of distinctive display of the patient status displayed on the screen. The distinctive display based on the interval patient status is given by M102 while the distinctive display based on the current patient status is given by M104. In the present embodiment, considering visibility, the distinctive display M104 is displayed larger, but the two displays may have the same size, or may be formed different in shape and position.

20

25

[0113]

FIG. 14(b) shows an example of distinctive display of each patient status. For example, M110 shows normal, M112 shows caution, and M114 shows warning. Here, the display may be differentiated according to color, movement or shape. For example, in the case of color, normal may be indicated by "white", caution by "yellow" and warning by "red".

[0114]

The operation will be briefly described with reference to FIGS. 14(c) to 14(e). Herein, it is assumed that the last logout time is t1 and the current point of time is t2.

[0115]

In FIG. 14(c), though the patient status was "normal" at the time t1, the state once became worse to "warning", then transited to, and has stayed in, the "caution" state until t2.

[0116]

In this case, the distinctive display M102 for the interval patient status is displayed with the "warning" state because the patient state became "warning" once after t1. Also, since the current status (at t2) is the caution level, the distinctive display M104 is displayed with the "caution" state.

[0117]

In FIG. 14(d), the patient status was in a "caution"

state at time t1, but the current state (at t2) is in a "normal" state. In this case, the distinctive display M102 for the interval patient status is categorized and displayed with the "caution" state. On the other hand, since the patient
5 state is "normal" at time t2, the distinctive display M104 displays "normal".

[0118]

FIG. 14(e) is a diagram showing a case where the patient states was in the "normal" state at time t1, but changed to
10 "caution" and "warning" from the middle of the interval. At the present (t2) as well, the patient state is at the "warning" level. In this case, the distinctive display M102 showing the interval patient status displays "warning", and the distinctive display M104 showing the current patient status
15 also displays "warning".

[0119]

Here in the description with FIG. 14, for description convenience, two kinds of distinctive displays are exemplified for explanation, but a plurality of distinctive
20 displays may be provided adaptively. For example, not only the above-described distinctive display of the above-mentioned patient's body (whole), but distinctive display based only on continuous biological information may be performed. Further, special distinctive display may be
25 performed in association with predetermined biological

information (e.g., respiration rate and the like).

[0120] [4.3.3 Screen Examples]

Next, explanation on execution of this processing will be given using screen examples. FIG. 15 shows an example of a patient status display screen W200. Displayed in the regions R202 and R204 on the display screen W200 are the name of the patient, the name of the doctor in charge and the like as the name plate information. These items are appropriately selected from the patient information registered in the electronic medical record and displayed.

[0121]

A region R206 is used as a pictogram region in which pictograms and the like are displayed. Further, displayed in a region R208 is special warning notice information from the caution information. The warning notice information is displayed in such a manner that only the experts such as medical staff and staff of nursing care facilities can understand.

[0122]

R210 notifies that an error has occurred. Here, in order to display the error content, it is necessary to perform authentication to switch to another screen. This configuration makes it possible to prevent those other than the experts such as medical staff, caregivers and the like from checking the error.

[0123]

Further, the operation and state of the state detection device 20 may be displayed on the display screen W200. For example, as shown in a region R212, the state may be displayed.

5 The connection status of the sensor is also displayed. This makes it possible to grasp if the sensor is unconnected or unavailable at a glance.

[0124]

In addition, patient status distinctive display is performed. In FIG. 15, the interval patient status distinctive display is given in M200 and the current patient status distinctive display in M202. Various methods are available to perform patient status distinctive display. For example, an underline may be displayed under the patient name to perform distinctive display by the color or thickness of the line. Alternatively, a separate icon may be displayed.

[0125]

Further, in the present embodiment, patient status distinctive display is performed on the entire biological information containing the continuous biological information and the measured biological information, but for example, display for the continuous biological information and that for the measured biological information may be separated. Further, each piece of biological information

may be displayed such that only the respiration as biological information is displayed separately.

[0126] [4.4 Biological Information Display Process]

Subsequently, biological information display processing will be described. The biological information display processing is a process corresponding to P106 in FIG. 9. That is, it is the process of displaying biological information values based on the patient's electronic medical record data.

[0127]

FIG. 16 shows a display screen W300 as a screen example when this processing is executed. Displayed on the display screen W300 are biological information values for individual biological information. In a region R302, the date and time when the displayed biological information value was registered is displayed.

[0128]

Further, beside the biological information value the alarm thresholds are displayed in a region R304 for easy viewing. That is, the alarm thresholds are displayed so as to clarify the caution level range and the warning level range.

[0129]

Further, it is possible to configure the display such that the background is made distinctive when the displayed

biological information value falls in the caution level range or the warning level range. For example, in R306, "126 bpm" is displayed as the pulse rate. Since this biological information value is contained in the caution level range, the background is displayed distinctively with a caution level color (e.g., yellow) or the like.

[0130]

Further, distinctive display of various information may be given with the biological information. For example, R308 shows that the pulse sensor is set ON (i.e., the pulse rate can be obtained as continuous biological information) in distinctive display.

[0131]

Also, R310 is a display that causes medical staffs and carer staffs and the like to pay attention. For example, it is possible to display the biological information which have caused trouble from the last logout up to the current login, in distinctive display. With this, when, for example, the current patient status distinctive display is "caution", it is possible for the staff to confirm that the patient has had some problem with respiration as he/she logs in.

[0132] [4.5 Graph Display Process]

Next, graph display processing will be described. The graph display processing is a process executed in P108 of FIG. 9. That is, this is a process that displays the

transition of the biological information registered in the electronic medical record as a graph.

[0133]

FIG. 17 shows a display screen W400 as a screen example when this process is effected. The display screen W400 displays the transition of each biological information value. The ranges defined by the alarm thresholds are also displayed in the graph of each biological information. This enables easy grasp when an anomaly arises in each biological information.

[0134]

Here, it is possible to provide such a configuration that when one of biological information is selected during display of this graph, the graph of the selected biological information alone is displayed.

[0135] [4.6 Electronic Medical Record Registering Process]
[4.6.1 Processing Flow]

Next, an electronic medical record registering process for registering biological information in the electronic medical record will be described with reference to FIG. 18. The electronic medical record registering process is a process executed by the control unit 100 which reads out and executes the electronic medical record registering program 138 stored in the storage unit 110.

[0136]

First, the patient information is read out (Step S402), so as to retrieve the biological information of the patient from the personal electronic medical record data 120 (Step S404). The kinds of biological information, the alarm thresholds and the like retrieved herein may be read out based on the patient basic information (e.g., patient ID) or the like, or may be set in common.

[0137]

Subsequently, the continuous biological information is received from the state detection device 20 so that the values of the received biological information are displayed (Step S408). At this stage, when a command of entering biological information is given (Step S410: Yes), the biological information value is manually entered (Step S412).

[0138]

At this time, distinctive display may be performed when the biological information value falls in the alarm range. For example, the background or characters may be displayed with yellow when the biological information value falls in the caution level range, and may be displayed with red when the value falls in the warning level range. This arrangement enables the medical staff and the nursing care staff to grasp the biological information that is currently causing a problem, and also can alert the user to erroneous input and the like.

[0139]

Further, as the continuous biological information to be displayed on the display screen, biological information (biological information values) that can be detected from the state detection device 20 may be updated as necessary, read out and displayed, or the biological information read out at a certain time may be displayed.

[0140]

If the measured biological information is received from the other measuring device 60 (Step S414: Yes), the measured biological information is stored (Step S416). In this case, the currently displayed biological information value is updated and stored in the personal electronic medical record data 120.

[0141]

Here, the time when the measured biological information is received from the other measuring device 60 is not limited. In this figure, the example is represented by Step S416, but the measured biological information that has been received previously may also be used. Also, the measured biological information may be arbitrarily stored in the personal electronic medical record data 120 (that is, the electronic medical record data 452). For example, if the value once measured is incorrect, the value is not stored and the value remeasured may be stored instead.

[0142]

If a command of registering the electronic medical record is given (Step S418: Yes), the electronic medical record data 452 of the electronic medical record server 40 is registered (Step S420).

[0143] [4.6.2 Screen Example]

FIG. 19 is a diagram showing a display screen W500 as an example when this process is executed. Displayed on the display screen W500 are individual biological information with the values thereof. As in FIG. 16, the alarm thresholds are displayed in a region R502. When each biological information value falls in the caution level or the warning level, distinctive display is performed like R504.

[0144]

Further, as shown in the region R506, the previously measured value may be displayed together. Over the biological information, the date and time when the last measurement was taken are also displayed. Thereby, the medical staff, the nursing staff and others can notice the change of the biological information value.

[0145]

As to the displayed biological information values, for continuous biological information the values updated in real time may be displayed or the values at a certain point of time may be displayed. Alternatively, the values stored in

the electronic medical record data (personal electronic medical record data 120 or electronic medical record data 452) may be displayed.

[0146]

5 Then, selecting "register" on this screen makes it possible to register (store) the currently displayed biological information values as the electronic medical record data. By referring to the history, it is possible to check the past biological information values.

10 [0147] [4.7 Reminder Process]

 Next, a reminder process will be described. The reminder process is a process which allows the staff and medical staff (nurses, etc.) to register what to do next as a reminder. For example, FIG. 20 shows an example of a display screen W600 displayed when this process is executed. By registering tasks to be displayed as various reminders, it is possible to display a reminder on the patient status display screen or the alarm display screen.

[0148] [4.8 Patient Information Display Process]

20 Next, a patient information display process will be described. The patient information display process is a process enables display of information on the patient. For example, it is possible to display, input and set basic information, medical care information, caution information
25 pictogram and the like of the patient.

[0149]

For example, FIG. 21 shows an example of a display screen W700 displayed when this process is effect. The display screen W700 reads out fundamental information (basic information) such as the name, gender and blood type of the patient from the electronic medical record and display them.

[0150] [4.9 Alarm Setting/History Process]

Next, an alarm setting/history process will be explained. This process is a process enabling the setting of each alarm threshold and the setting as to whether or not an alarm is permitted. It is also possible to check a history of alarms that occurred in the past.

[0151]

FIG. 22 shows an example of a display screen W800 displayed when the alarm setting/history process is executed. In the display screen W800, alarm thresholds can be individually set. For example, as the upper alarm thresholds, the threshold of the caution level range can be set in R804 and the threshold of the warning level range can be set in R802.

[0152]

Further, as the lower alarm threshold, the threshold of the caution level range can be set in R808 and the threshold of the warning level range can be set in R806.

[0153]

It is also possible to set whether or not to output an alarm when the information value falls in the caution level or warning level. For example, the setting in R810 indicates that no alarm (notice) is given.

5 [0154]

In a display screen W850 of FIG. 23, the setting in R850 indicates that an alarm is output when the information value falls in the caution level. It should be noted that this setting may enable designation of, for example, sound alarm,
10 light alarm or the like, and may also enable different alarm settings for the caution level and warning level.

[0155]

[5. Effect By Patient Status Display Device Configuration]

It is also one of the features of the present embodiment
15 that these screens can be displayed in a place apart from the bed 3. This makes it easier for a nurse or a doctor to refer to patient information, and even if the bed is changed, appropriate patient information can be displayed.

[0156]

20 In particular, in the prior art, the display screen installed in the bed is not easy to handle, and it was necessary to update the pictogram displayed on the bedside every time, which was inconvenient.

[0157]

25 In addition, information that can be acquired in the

bed (e.g., the continuous biological information in the present embodiment) and information that can be acquired from the measurement device (e.g., the measured biological information in the present embodiment) have to be managed separately. All of these information can be connected via the patient condition display device 10 (connection device 2000), and can also be stored in the electronic medical record.

[0158]

FIG. 24 shows an example where an error notification is given to the connection device 2000. The display terminal 1000 is connected to the connection device 2000 and integrally arranged on the bed side.

[0159]

Here, for example, when it is not possible to connect with the state detection device 20, "Connect Sensor" is displayed in a region R900. Nothing is displayed in this region when there is no error. This makes it possible to reliably notify important errors and others, regardless of what kind of screen the display terminal 1000 is, or even in a case where the display terminal 1000 can not be displayed (e.g., a failure, a case where the display terminal 1000 is not connected, etc.).

[0160]

In addition, the error notification may be made based

on the state of the patient. In this case, indications (symbols, codes, etc.) which are not understood by the patient, their family and the like may be displayed. Also, the notifying method is not limited to display but, for example, sounding or notifying to the portable terminal device 55 may be performed.

[0161] [Service Provision From Server and Other Provision]

Though, for convenience of explanation, the description above was given on the assumption that the processing in the embodiment is implemented by the patient status display device 10, it is possible to provide a configuration in which the processing is executed in the server 30 so that the result can be received by the patient status display device 10.

[0162]

That is, various programs (e.g., the main program 132, the alarm program 134, the patient status display program 136, the electronic medical record registering program 138) are executed on the server 30 as necessary. The patient status display device 10 transmits biological information to the server 30 while the server 30 is accessed by, for example, a WEB browser or a dedicated application, whereby it is possible to realize the same processing.

[0163]

In addition, though the patient status display device 10 is also configured separately of the display terminal 1000

and the connection device 2000, these components may be integrated and presented as a dedicated patient status display device 10.

[0164]

5 Separation of the display terminal 1000 and the connection device 2000 produces such an advantage as to enable use of a tablet terminal satisfying predetermined conditions as the display terminal 1000. Thus, it is possible to consider use of commercially available tablet terminals,
10 computers and smartphones.

[0165]

 Further, the patient status display device 10 is typically installed near the bed, whereas the same screen can be displayed on the terminal device 50 and the portable
15 terminal device 55. For example, checking patient information with the portable terminal device 55 even while the nurse is rounding and use of the terminal device 50 at the nurse station, makes it possible to collectively manage the patient with other patients in a unified manner.

20 [0166]

 Moreover, even in medical treatment or during examination, biological information can be updated at any time through the terminal device 50, it is hence possible to improve the handling of electronic medical records.

25 [0167] [7. Modified Example]

Though the embodiment of the present invention has been described in detail with reference to the drawings, the specific configuration is not limited to this embodiment, and designs and others that do not depart from the gist of this invention should also included in the scope of claims.

[0168]

The programs to run in each device of the embodiment may be programs (programs that make a computer function) for controlling a CPU or the like so as to realize the functions of the embodiment described above. The information to be handled in these devices is temporarily stored in temporary memory (e.g., RAM) at the time of processing, then is stored into storages such as various kinds of ROM and/or HDDs, and is read out, modified and written in by the CPU, as necessary.

[0169]

Herein, the recording medium for storing the program may be any of semiconductor mediums (e.g., ROM, non-volatile memory card, etc.), optical recording mediums/magneto optical mediums (e.g., DVD (Digital Versatile Disc), MO (Magneto Optical Disc), CD (Compact Disc), BD and the like), magnetic recording mediums (e.g., magnetic tape, flexible disc, etc.), and the like. Further, the functions of the above-described embodiments are not only realized by executing the loaded program, but the functions of the present invention may also be realized by processing in cooperation

with an operating system, another application program or the like, based on the instructions of the running program.

[0170]

To put the product on the market, the program may be stored on a removable storing medium, or may be transferred to a server computer connected to a network such as the Internet or the like. In this case, it goes without saying that the storage device of the server computer is also included in the present invention.

[0171]

Further, the whole or part of each device in the above-described embodiments may also be typically realized by an LSI (Large Scale Integration) as an integrated circuit. The functional block of each device may be given individually in the form of a chip, or the whole or part may be integrated into a chip. The method of circuit integration may be realized in the form of a dedicated circuit or general purpose processor, not limited to LSI. It goes without saying that if a technology of circuit integration replacing LSI technologies appears with the progress of semiconductor technologies, the integrated circuit based on that technology can also be used.

CLAIMS

[Claim 1]

A patient status determination device comprising:

5 a continuous biological information receiving means for receiving continuous biological information from a status detecting device continuously detecting biological information on a patient;

10 a measured biological information receiving means for receiving measured biological information from a measuring device measuring the biological information of the patient; and,

a determining means for determining a status of the patient, based on the continuous biological information and the measured biological information.

15

[Claim 2]

The patient status determination device according to claim 1, wherein the determining means determines a current status of the patient based on the continuous biological information currently being received and the measured biological information.

20

[Claim 3]

The patient status determination device according to claim 2, wherein the determining means determines a state

25

as a warning status when there has been a state that either the continuous biological information or the measured biological information exceeded a predetermined threshold and other than the foregoing determines a state as a normal level.

[Claim 4]

The patient status determination device according to claim 2 or 3, wherein the determining means determines a status of the patient in a time interval based on the continuous biological information received in the time interval from a reference point of time up to a present time and the measured biological information.

[Claim 5]

The patient status determination device according to any one of claims 1 to 4, further comprising a warning means for alarming, based on the status of the patient determined by the determining means.

[Claim 6]

The patient status determination device according to claim 4, further comprising a distinctive display means for performing a distinctive display, based on the status of the patient determined by the determination means,

wherein the distinctive display means distinctively displays the current status of the patient and the status of the patient in the time interval, determined by the determining means.

5

[Claim 7]

A patient status determination method comprising:

a continuous biological information receiving step of receiving continuous biological information from a status
10 detecting device continuously detecting biological information on a patient;

a measured biological information receiving step of receiving measured biological information from a measuring device measuring biological information of the patient; and,

15 a determining step of determining a status of the patient, based on the continuous biological information and the measured biological information.

[Claim 8]

20 A program for causing a computer to execute:

a continuous biological information receiving function of receiving continuous biological information from a status detecting device continuously detecting biological information on a patient;

25 a measured biological information receiving function

of receiving measured biological information from a
measuring device measuring biological information of the
patient; and,

5 a determining function of determining a status of the
patient, based on the continuous biological information and
the measured biological information.
