

NUCLEIC ACID ANALYSIS

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to US provisional applications 61,226,025 and 61,226,106, both filed on July 16, 2009, each of which is incorporated herein by reference in its entirety.

FIELD OF INVENTION

[0002] The present invention relates to the general fields of nucleic acid analysis in human or other animal subjects, particularly the procurement and analysis of high quality nucleic acids from a biological sample, and in particular, from microvesicles.

BACKGROUND

[0003] Small microvesicles shed by cells are known as “exosomes” (Thery et al., 2002). Exosomes are reported as having a diameter of approximately 30-100 nm and are shed from many different cell types under both normal and pathological conditions (Thery et al., 2002). Exosomes are classically formed from the inward invagination and pinching off of the late endosomal membrane. This results in the formation of a multivesicular body (MVB) laden with small lipid bilayer vesicles (~40-100 nm in diameter), each of which contains a sample of the parent cell’s cytoplasm (Stoorvogel et al., 2002). Fusion of the MVB with the cell membrane results in the release of these exosomes from the cell, and their delivery into the blood, urine or other bodily fluids.

[0004] Another category of cell-derived vesicles are known as “shedding microvesicles” (Cocucci et al., 2009). These microvesicles, formed by directly budding off of the cell’s plasma membrane, are more heterogeneous in size than exosomes, and like exosomes, also contain a sample of the parent cell’s cytoplasm. Exosomes and shedding

microvesicles co-isolate using ultracentrifugation and ultrafiltration isolation techniques and will, therefore, be collectively referred to here as microvesicles.

[0005] Recent studies reveal that nucleic acids within microvesicles have a role as biomarkers. For example, Skog et. al. describes, among other things, the use of nucleic acids extracted from microvesicles in GBM patient serum for medical diagnosis, prognosis and therapy evaluation (Skog et al., 2008). The use of nucleic acids extracted from microvesicles is considered to potentially circumvent the need for biopsies, highlighting the enormous diagnostic potential of microvesicle biology (Skog et al., 2008).

[0006] In research and development, as well as commercial applications of nucleic acid biomarkers, it is desirable to extract high quality nucleic acids from biological samples in a consistent and reliable manner. The present invention provides compositions of high quality nucleic acid extractions from microvesicles and other biological samples, methods of making such extractions, and methods of using these high quality nucleic acids in various applications.

BRIEF SUMMARY OF THE INVENTION

[0007] In one aspect, the invention is a novel nucleic acid extraction from one or more microvesicles isolated from a eukaryotic biological sample, wherein 18S rRNA and 28S rRNA are detectable in the extraction. Preferably, the quantitative ratio of 18S rRNA to 28S rRNA detectable in the novel extractions is within the range of approximately 1:1 to approximately 1:2; and is preferably approximately 1:2. Biological samples from which the novel extraction may be obtained include, among other things, any bodily fluid, preferably urine, serum or plasma, and preferably, are from a mammal, particularly a human. For bodily fluid samples with a protein concentration of less than 10 mg/ml, such as urine, the novel nucleic acid extraction may further comprise a nucleic acid extraction having an RNA Integrity Number (in all cases, as obtained on an Agilent BioAnalyzer or an equivalent

thereof) of greater than or equal to 5 and/or may further comprise a nucleic acid yield from 20 ml of biological sample of greater than or equal to 50 pg/ml. Similarly, for bodily fluid samples with a protein concentration of greater than 10 mg/ml, such as serum or plasma, the novel nucleic acid extraction may further comprise an RNA Integrity Number of greater than or equal to 3 and/or may further comprise a nucleic acid yield from 1 ml of biological sample is greater than or equal to 50 pg/ml.

[0008] In another aspect, the invention is a novel profile of nucleic acid from one or more microvesicles isolated from a eukaryotic biological sample, wherein 18S rRNA and 28S rRNA are detectable in the profile. Preferably, the quantitative ratio of 18S rRNA to 28S rRNA detectable in the novel profile is within the range of approximately 1:1 to approximately 1:2; and is preferably approximately 1:2. Biological samples from which the novel profile may be obtained include, among other things, any bodily fluid, preferably urine, serum or plasma, and preferably, is from a mammal, particularly a human. For bodily fluid samples with a protein concentration of less than 10 mg/ml, such as urine, the novel profile may further comprise an RNA Integrity Number of greater than or equal to 5 and/or may further comprise a nucleic acid yield from 20 ml of biological sample of greater than or equal to 50 pg/ml. Similarly, for bodily fluid samples with a protein concentration of greater than 10 mg/ml, such as serum or plasma, the novel profile may further comprise an RNA Integrity Number of greater than or equal to 3 and/or may further comprise a nucleic acid yield from 1 ml of biological sample is greater than or equal to 50 pg/ml.

[0009] In yet another aspect, the invention is a method of evaluating the quality of a nucleic acid extraction from microvesicles isolated from a eukaryotic biological sample, comprising the steps of: (a) extracting RNA from microvesicles; and (b) measuring the quality of the RNA by determining the quantity of 18S and 28S rRNA in the extraction. Preferably, the quantitative ratio of 18S rRNA to 28S rRNA determined in the novel method

is within the range of approximately 1:1 to approximately 1:2; and is preferably approximately 1:2. Biological samples on which the novel method may be performed include, among other things, any bodily fluid, preferably urine, serum or plasma, and preferably, is from a mammal, particularly a human. For bodily fluid samples with a protein concentration of less than 10 mg/ml, such as urine, the novel method may further result in the extraction of nucleic acid having an RNA Integrity Number of greater than or equal to 5 and/or may further result in a nucleic acid yield from 20 ml of biological sample of greater than or equal to 50 pg/ml. Similarly, for bodily fluid samples with a protein concentration of greater than 10 mg/ml, such as serum or plasma, the novel method may further result in the extraction of nucleic acid having an RNA Integrity Number of greater than or equal to 3 and/or may further result in a nucleic acid yield from 1 ml of biological sample is greater than or equal to 50 pg/ml.

[0010] In a further aspect, the invention is a method of obtaining nucleic acid from a biological sample, comprising the steps of: (a) obtaining a biological sample; (b) performing an extraction enhancement operation on the biological sample; and (c) extracting nucleic acid from the biological sample. The extraction enhancement operation is comprised of: (a) the addition of one or more enhancement agents to the biological sample; or (b) the performance of one or more enhancement steps prior to nucleic acid extraction; or (c) a combination of enhancement agents and enhancement steps. The enhancement agents may include: (i) RNase inhibitor; (ii) protease; (iii) reducing agent; (iv) decoy substrate, such as synthetic RNA; (v) soluble receptor; (vi) small interfering RNA; (vii) RNA binding molecule, such as anti-RNA antibody, chaperone protein, or an RNase inhibitory protein; (ix) RNase denaturing substance, such as high osmolarity solution or detergent. The extraction enhancement steps may include: (x) washing; (xi) size-separating RNase from the sample; (xii) effecting RNase denaturation through a physical change, such as by decreasing temperature, or executing a

freeze/thaw cycle. The novel method may be performed on a biological sample including, among other things, any bodily fluid, preferably urine, serum or plasma, and preferably, is from a mammal, particularly a human. In one embodiment, a derivative is obtained from the biological sample and subjected to the extraction enhancement operation before extracting nucleic acid. Preferably, the derivative is a microvesicle fraction from the biological sample. In one embodiment, the microvesicle fraction is obtained by a filtration concentration technique, however other known isolation techniques may be utilized as well. In a further aspect of the inventive method, the derivative may be treated with a ribonuclease, deoxyribonuclease, or a combination thereof, prior to performance of the enhancement extraction operation. In some aspects, the extraction enhancement operation includes the addition of an RNase inhibitor to the biological sample, or to the derivative, prior to extracting nucleic acid; preferably the RNase inhibitor has a concentration of greater than 0.027 AU (1X) for a sample equal to or more than 1 μ l; alternatively, greater than or equal to 0.135 AU (5X) for a sample equal to or more than 1 μ l; alternatively, greater than or equal to 0.27 AU (10X) for a sample equal to or more than 1 μ l; alternatively, greater than or equal to 0.675 AU (25X) for a sample equal to or more than 1 μ l; and alternatively, greater than or equal to 1.35 AU (50X) for a sample equal to or more than 1 μ l, wherein the 1X protease concentration refers to an enzymatic condition wherein 0.027 AU or more protease is used to treat microvesicles isolated from 1 μ l or more bodily fluid; the 5X protease concentration refers to an enzymatic condition wherein 0.135 AU or more protease is used to treat microvesicles isolated from 1 μ l or more bodily fluid; the 10X protease concentration refers to an enzymatic condition wherein 0.27 AU or more protease is used to treat microvesicles isolated from 1 μ l or more bodily fluid; the 25X protease concentration refers to an enzymatic condition wherein 0.675 AU or more protease is used to treat microvesicles isolated from 1 μ l or more bodily fluid; the 50X protease concentration refers to an enzymatic condition

wherein 1.35 AU or more protease is used to treat microvesicles isolated from 1 μ l or more bodily fluid. Preferably, the RNase inhibitor is a protease.

[0011] In a still further aspect, the invention is a novel kit for obtaining nucleic acids from microvesicles, comprising in one or more containers: (a) a nucleic acid extraction enhancement agent; (b) DNase, RNase, or both; and (c) a lysis buffer. The novel kit may further comprise instructions for using the kit. In the novel kits of this invention, the nucleic acid extraction enhancing agent may include: (a) RNase inhibitor; (b) protease; (c) reducing agent; (d) decoy substrate; (e) soluble receptor; (f) small interfering RNA; (g) RNA binding molecule; (h) RNase denaturing substance; or (i) any combination of any of the foregoing agents as a mixture or individually.

[0012] In yet another aspect, the invention is a novel method of analyzing RNA from microvesicles, comprising the steps of: (a) obtaining a sample of microvesicles; (b) treating the sample with DNase to eliminate all or substantially all of any DNA located outside of or on the surface of the microvesicles in the sample; (c) extracting RNA from the sample; and (d) analyzing the extracted RNA. The novel method may be performed on a biological sample including, among other things, any bodily fluid, preferably urine, serum or plasma, and preferably, is from a mammal, particularly a human.

[0013] In a further aspect, the invention is a novel method for diagnosing, monitoring, or treating a subject, comprising the steps of: (a) isolating a microvesicle fraction from a urine sample from a subject; (b) detecting the presence or absence of a biomarker within the microvesicle fraction; wherein the biomarker is selected from the group consisting of (i) a species of nucleic acid, (ii) the level of expression of a nucleic acid, (iii) a nucleic acid variant, and (iv) any combination of any of the foregoing; and wherein the biomarker is associated with the presence or absence of a disease or other medical condition, or the viability of a treatment option. In some aspects, the biomarker is an mRNA transcript; for

instance, the mRNA transcript may be selected from the group consisting of: NPHS2 (podocin), LGALS1 (Galectin-1), HSPG2 (heparin sulfate proteoglycan); CUBN (cubilin), LRP2 (megalin), AQP1 (aquaporin 1), CA4 (carbonic anhydrase 4), CLCN5 (chloride channel protein 5), BDKRB1 (bradykinin B1 receptor), CALCR (calcitonin receptor), SCN1D (amiloride-sensitive sodium channel subunit delta), SLC12A3 (thiazide-sensitive sodium-chloride cotransporter), AQP2 (aquaporin 2), ATP6V1B1 (V-ATPase B1 subunit), SLC12A1 (kidney-specific Na-K-Cl symporter via RT-PCR of RiboAmped mRNA); more preferably, the mRNA transcript is AQP2 (aquaporin 2) or ATP6V1B1 (V-ATPase B1 subunit). In further aspects of the novel methods, the biomarker and disease or other medical condition are selected from the group consisting of: (a) NPHS2 (podocin) and glomerular disease, such as steroid-resistant nephritic syndrome; (b) CUBN (cubilin) and proteinuria, such as in Imerslund-Gräsbeck syndrome; and (c) AQP2 (aquaporin 2) and diabetes insipidus.

[0014] In yet another aspect, the invention is an isolated polynucleotide molecule comprising a first nucleotide sequence that is at least 90% identical to a second nucleotide sequence selected from the group consisting of SEQ ID NOS: 1-29; an isolated polynucleotide comprising a segment of a nucleotide sequence selected from SEQ ID NOS: 1-29; or an isolated polynucleotide comprising a sequence of at least 13 nucleotides that are the same as any 13-nucleotide sequence in any one of SEQ ID NOS: 1-29. In particular, the foregoing polynucleotide molecules may be a deoxyribonucleotide or a ribonucleotide. In other aspects the invention is a vector comprising any of the foregoing isolated nucleic acid molecules. In still other aspects, the invention is a host cell comprising any of the foregoing vectors or any of the foregoing isolated nucleic acid molecules.

[0015] In a further aspect, the invention is a novel method of assessing the quality of a nucleic acid extraction from a biological sample, comprising: (a) providing a biological sample; (b) obtaining an extraction of nucleic acids from the biological sample; (c) measuring

the amount of a polynucleotide molecule comprising a segment having a nucleotide sequence selected from SEQ NOS: 1-29 in the extraction; and (d) comparing the amount of the polynucleotide molecule against a standard to assess the quality of the nucleic acid extraction. The novel method may be performed on any biological sample, for example, a bodily fluid, in particular, urine, serum or plasma, preferably from a mammal such as a human. This novel method may be used in conjunction with any of the foregoing novel nucleic acid extractions or novel extraction methods. In particular, the standard used to assess the quality of the nucleic acid extraction may be derived by measuring the amount of a polynucleotide molecule comprising a segment having the nucleotide sequence selected from SEQ NOS: 1-29 in nucleic acid extractions from more than 5 biological samples.

BRIEF DESCRIPTION OF THE DRAWINGS

[0016] FIGURE 1, frames a to f, are electron microscopy pictures of urinary multivesicular bodies. Multivesicular bodies (MVB) can be identified in various regions of the nephron and collecting duct (see arrows). Podo – podocyte, PT – proximal tubule, TDL – thin descending limb, TAL – thick ascending limb, CD-PC – collecting duct principal cell, CD-IC – collecting duct intercalated cell. Scale bar = 200 nm for a, c, d, e, f; 500 nm for b.

[0017] FIGURE 2 is an electron microscopy picture of isolated urinary microvesicles. Human urinary microvesicles isolated via differential ultracentrifugation and imaged via TEM using phosphotungstic acid as a stain. The scale bar = 200 nm.

[0018] FIGURE 3 is a plot depicting RNA profiles generated with a method of 100kDa MWCO filters. An Agilent BioAnalyzer was used to generate the plot.

[0019] FIGURE 4 is a plot depicting RNA profiles generated with a method of ultracentrifugation. An Agilent BioAnalyzer was used to generate the plot.

[0020] FIGURE 5 is a pair of plots depicting RNA profiles generated with a three step pre-processing method of x300g spin, x17,000g spin, and 0.8 μ m filtration (A), or with a

one step pre-processing method of only a 0.8 μm filtration (**B**), in each case followed by ultracentrifugation. An Agilent BioAnalyzer was used to generate the plots.

[0021] FIGURE 6 is a pair of plots depicting RNA profiles generated with a three-step pre-processing method of x300g spin, x17,000g spin, and 0.8 μm filtration (**A**), or with a one step pre-processing method of only a 0.8 μm filtration (**B**), in each case followed by filtration concentration. An Agilent BioAnalyzer was used to generate the plots.

[0022] FIGURE 7 is a flow chart depicting a new method of nucleic acid extraction from urine with an extraction enhancement operation.

[0023] FIGURE 8 is a pair of plots depicting RNA profiles generated with methods using 5X versus 10X concentrated proteases. Microvesicles were isolated via filtration concentrators from 20ml urine samples. Plot **A** represents the profile obtained with 5X protease. Plot **B** represents the profile obtained with 10X protease. A 1X protease concentration refers to an enzymatic condition wherein 0.027 AU or more protease is used to treat microvesicles isolated from 1 μl or more bodily fluid. A 5X protease concentration refers to an enzymatic condition wherein 0.135 AU or more protease is used to treat microvesicles isolated from 1 μl or more bodily fluid. One mAU is the protease activity that releases folin-positive amino acids and peptides corresponding to 1 μmol tyrosine per minute.

[0024] FIGURE 9 is a pair of plots depicting RNA profiles generated with methods using 25X versus 50X concentrated proteases. Microvesicles were isolated via filtration concentrators from 40ml urine samples. Plot **A** represents the profile obtained with 25X protease. Plot **B** represents the profile obtained with 50X protease. 1X protease refers to 0.027 AU. One mAU is the protease activity that releases folin-positive amino acids and peptides corresponding to 1 μmol tyrosine per minute.

[0055] FIGURE 40 is a trio of plots depicting RNA profiles generated from urinary microvesicles. Urinary microvesicles were washed but were not treated with any RNase inhibitor before the microvesicle membranes were broken for nucleic acid extraction. Three samples were used in this group of extractions. The profiles are shown in **A**, **B** and **C**, respectively.

[0056] FIGURE 41 is a trio of plots depicting RNA profiles generated from urinary microvesicles. Urinary microvesicles were washed and treated with RNase inhibitor before microvesicle membranes were broken for nucleic acid extraction. Three samples were used in this group of extractions. The profiles are shown in **A**, **B** and **C**, respectively.

[0057] FIGURE 42 is a list of chromosome regions in which there were more than 500 transcript hits in a deep sequencing analysis of RNA extracted from urinary microvesicles (“spikes”). The numbers indicate the start and end point of each chromosomal region. For example, “chr1.-1.91625366.91625741” refers to the region on human chromosome 1 between nucleotide nos. 91625366 and 91625741. The corresponding SEQ ID NOS are also indicated.

[0058] FIGURE 43 is a list of primers used for PCR reaction to amplify sequences in 10 chromosome regions as indicated. For example, “chr1.-1.91625366.91625741” refers to the region on human chromosome 1 between nucleotide nos. 91625366 and 91625741. The

primer pair used to amplify this region was “tccagctcacgttcctatt 1L and ccaggtggggagtttgact 1R”. Primers run from 5’ to 3’ as they go from left to right.

[0059] FIGURE 44 is a pair of BioAnalyzer pseudo gels depicting the result of PCR amplification of 10 spike-rich chromosome regions. The numbering of the lanes at the top of each frame corresponds to the numbering of the chromosome regions shown in Figure 43. In **A**, a nucleic acid extraction from urinary microvesicles was used as a template for the PCR. In **B**, a nucleic acid extraction from renal tissue was used as a template for the PCR.

[0060] FIGURES 45-73 are plots depicting the spikes in 29 chromosome regions. The regions are indicated at the top of each plot. For example, the plot in Figure 46 refers to the region of “chr1.-1.91625366.91625741,” which is the region on human chromosome 1 between nucleotide nos. 91625366 and 91625741.

DETAILED DESCRIPTION

[0061] Microvesicles are shed by eukaryotic cells, or budded off of the plasma membrane, to the exterior of the cell. These membrane vesicles are heterogeneous in size with diameters ranging from about 10 nm to about 5000 nm. The small microvesicles (approximately 10 to 1000 nm, and more often approximately 10 to 200 nm in diameter) that are released by exocytosis of intracellular multivesicular bodies are referred to in the art as “exosomes.” The compositions, methods and uses described herein are equally applicable to microvesicles of all sizes; preferably 10 to 800 nm; and more preferably 10 to 200 nm.

[0062] In some of the literature, the term “exosome” also refers to protein complexes containing exoribonucleases which are involved in mRNA degradation and the processing of small nucleolar RNAs (snoRNAs), small nuclear RNAs (snRNAs) and ribosomal RNAs (rRNA) (Liu et al., 2006; van Dijk et al., 2007). Such protein complexes do not have membranes and are not “microvesicles” or “exosomes” as those terms are used here in.

[0063] The present invention is partly based on the discovery that adverse factors can prevent an effective extraction of nucleic acids from a biological sample and that novel and unexpected agents and steps may be used to mitigate or remove the adverse factors, thereby dramatically improving the quality of the extracted nucleic acids. As such, one aspect of this invention are novel methods for extracting high quality nucleic acids from a biological sample. The high quality extractions obtained by the novel methods described herein are characterized by high yield and high integrity, making the extracted nucleic acids useful for various applications in which high quality nucleic acid extractions are preferred.

[0064] Broadly described, the novel methods include, for example, the steps of obtaining a biological sample, mitigating or removing the adverse factors that prevent an effective extraction of nucleic acids from a biological sample, and extracting nucleic acids from the biological sample followed, optionally, by nucleic acid analysis.

[0065] Applicable biological samples include, for example, a cell, a group of cells, fragments of cells, cell products including for example microvesicles, cell cultures, bodily tissues from a subject, or bodily fluids. The bodily fluids can be fluids isolated from anywhere in the body of the subject, preferably a peripheral location, including but not limited to, for example, blood, plasma, serum, urine, sputum, spinal fluid, pleural fluid, nipple aspirates, lymph fluid, fluid of the respiratory, intestinal, and genitourinary tracts, tear fluid, saliva, breast milk, fluid from the lymphatic system, semen, cerebrospinal fluid, intra-organ system fluid, ascitic fluid, tumor cyst fluid, amniotic fluid and combinations thereof.

[0066] A biological sample may sometimes come from a subject. The term “subject” is intended to include all animals shown to or expected to have microvesicles. In particular embodiments, the subject is a mammal, a human or nonhuman primate, a dog, a cat, a horse, a cow, other farm animals, or a rodent (e.g. mouse, rat, guinea pig, etc.). The term “subject” and “individual” are used interchangeably herein.

[0067] A biological sample may optionally be processed to obtain a biological sample derivative before, after, or at the same time as, carrying out the step of mitigating or removing the adverse effects. The biological sample derivative may be a cell, cell debris, a membrane vesicle, or a microvesicle.

[0068] A biological sample is sometimes pre-processed before a biological sample derivative such as a microvesicle is obtained. In some instances, the pre-processing step is preferred. For example, a urine sample is may be pre-processed to obtain urinary microvesicles. The pre-processing may be achieved by techniques known in the art such as low speed centrifugation and pre-filtration. For example, urine samples may undergo a first centrifugation step of 300g to get rid of large particles in the samples. Urine samples may undergo a second centrifugation step of 17,000g to get rid of smaller particles in the samples. After the second centrifugation step, urine samples may further undergo a pre-filtration step, e.g., a 0.8um pre-filtration step. Alternatively, urine samples may be pre-processed by a – pre-filtration step without first undergoing the one or more of the centrifugation steps.

[0069] Membrane vesicles, e.g., microvesicles, may be isolated from a biological sample. In some instances, such isolation may be carried out without pre-processing the biological sample in some instances. In other instances, such isolation may be carried out after the biological sample is pre-processed. The isolation step may be advantageous for high quality nucleic acid extraction from a biological sample. For example, the isolation may give rise to advantages such as: 1) the opportunity to selectively analyze disease- or tumor-specific nucleic acids, which may be obtained by isolating disease- or tumor-specific microvesicles apart from other microvesicles within the fluid sample; 2) significantly higher yield of nucleic acid species with higher integrity as compared to the yield/integrity obtained by extracting nucleic acids directly from the fluid sample; 3) scalability, e.g. to detect nucleic acids expressed at low levels, the sensitivity can be increased by pelleting more microvesicles

from a larger volume of serum; 4) purer nucleic acids in that protein and lipids, debris from dead cells, and other potential contaminants and PCR inhibitors are excluded from the microvesicle pellets before the nucleic acid extraction step; and 5) more choices in nucleic acid extraction methods as microvesicle pellets are of much smaller volume than that of the starting serum, making it possible to extract nucleic acids from these microvesicle pellets using small volume column filters.

[0070] Methods of isolating microvesicles from a biological sample are known in the art. For example, a method of differential centrifugation is described in a paper by Raposo et al. (Raposo et al., 1996), a paper by Skog et al. (Skog et al., 2008) and a paper by Nilsson et al. (Nilsson et al., 2009). Methods of anion exchange and/or gel permeation chromatography are described in US Patent Nos. 6,899,863 and 6,812,023. Methods of sucrose density gradients or organelle electrophoresis are described in U.S. Patent No. 7,198,923. A method of magnetic activated cell sorting (MACS) is described in a paper by Taylor and Gercel-Taylor (Taylor and Gercel-Taylor, 2008). A method of nanomembrane ultrafiltration concentration is described in a paper by Cheruvanky et al. (Cheruvanky et al., 2007). Further, microvesicles can be identified and isolated from bodily fluid of a subject by a newly developed microchip technology that uses a unique microfluidic platform to efficiently and selectively separate tumor-derived microvesicles (Chen et al.). Each of the foregoing references is incorporated by reference herein for its teaching of these methods.

[0071] In one embodiment of the methods described herein, the microvesicles isolated from a bodily fluid are enriched for those originating from a specific cell type, for example, lung, pancreas, stomach, intestine, bladder, kidney, ovary, testis, skin, colorectal, breast, prostate, brain, esophagus, liver, placenta, fetus cells. Because the microvesicles often carry surface molecules such as antigens from their donor cells, surface molecules may be used to identify, isolate and/or enrich for microvesicles from a specific donor cell type (Al-

Nedawi et al., 2008; Taylor and Gercel-Taylor, 2008). In this way, microvesicles originating from distinct cell populations can be analyzed for their nucleic acid content. For example, tumor (malignant and non-malignant) microvesicles carry tumor-associated surface antigens and may be detected, isolated and/or enriched via these specific tumor-associated surface antigens. In one example, the surface antigen is epithelial-cell-adhesion-molecule (EpCAM), which is specific to microvesicles from carcinomas of lung, colorectal, breast, prostate, head and neck, and hepatic origin, but not of hematological cell origin (Balzar et al., 1999; Went et al., 2004). In another example, the surface antigen is CD24, which is a glycoprotein specific to urine microvesicles (Keller et al., 2007). In yet another example, the surface antigen is selected from a group of molecules such as CD70, carcinoembryonic antigen (CEA), EGFR, EGFRvIII and other variants, Fas ligand, TRAIL, transferrin receptor, p38.5, p97 and HSP72. Additionally, tumor specific microvesicles may be characterized by the lack of surface markers, such as CD80 and CD86.

[0072] The isolation of microvesicles from specific cell types can be accomplished, for example, by using antibodies, aptamers, aptamer analogs or molecularly imprinted polymers specific for a desired surface antigen. In one embodiment, the surface antigen is specific for a cancer type. In another embodiment, the surface antigen is specific for a cell type which is not necessarily cancerous. One example of a method of microvesicle separation based on cell surface antigen is provided in U.S. Patent No. 7,198,923. As described in, e.g., U.S. Patent Nos. 5,840,867 and 5,582,981, WO/2003/050290 and a publication by Johnson et al. (Johnson et al., 2008), aptamers and their analogs specifically bind surface molecules and can be used as a separation tool for retrieving cell type-specific microvesicles. Molecularly imprinted polymers also specifically recognize surface molecules as described in, e.g., US Patent Nos. 6,525,154, 7,332,553 and 7,384,589 and a publication by Bossi et al. (Bossi et al., 2007) and are a tool for retrieving and isolating cell type-specific

microvesicles. Each of the foregoing references is incorporated herein for its teaching of these methods.

[0073] In instances when the intended biological derivative is a membrane vesicle such as a microvesicle, a step of removing nucleic acids that are not inside the microvesicle is sometimes performed. Methods of removing nucleic acids are well known in the art. For example, to remove such nucleic acids from a sample, an enzyme digestion step may be performed. Such enzymes may be a type of ribonuclease that catalyzes the enzymatic digestion of ribonucleic acids or a type of deoxyribonuclease that catalyzes the enzymatic digestion of deoxyribonucleic acids.

[0074] In one aspect of this invention, the novel nucleic acid extraction methods include a step of removing or mitigating adverse factors that prevent high quality nucleic acid extraction from a biological sample. Such adverse factors are heterogeneous in that different biological samples may contain various species of such adverse factors. In some biological samples, factors such as excessive extra-microvesicle DNA may affect the quality of nucleic acid extractions from such samples and contaminate DNA extracted from within microvesicle. In other samples, factors such as excessive endogenous RNase may affect the quality of nucleic acid extractions from such samples. Many agents and methods may be used to remove these adverse factors. These methods and agents are referred to collectively as an “extraction enhancement operation.”

[0075] In some instances, the extraction enhancement operation may involve the addition of nucleic acid extraction enhancement agents to the biological sample or derivative. To remove adverse factors such as endogenous RNases, such extraction enhancement agents as defined here may include, but are not limited to, a commercially available RNase inhibitor such as Suprase-In (Ambion Inc.), RNaseIN (Promega Corp.), or other agents that function in a similar fashion; a protease; a reducing agent; a decoy substrate such as a synthetic RNA;

a soluble receptor that can bind RNase; a small interfering RNA (siRNA); a RNA binding molecule, such as an anti-RNA antibody, or a chaperone protein; a RNase denaturing substance, such as a high osmolarity solution, a detergent, or a combination thereof. These enhancement agents may exert their functions in various ways, for example, but not limited to, through inhibiting RNase activity (e.g., RNase inhibitors), through a ubiquitous degradation of proteins (e.g., proteases), or through a chaperone protein (e.g., a RNA-binding protein) that binds and protects RNAs. In all instances, such extraction enhancement agents remove or mitigate some or all of the adverse factors in the biological sample that would otherwise prevent or interfere with the high quality extraction nucleic acids from the biological sample.

[0076] In other instances, the extraction enhancement operation may involve the performance of one or more process steps. Such processes include extensive or substantially thorough washing of nucleic acid-containing components of the sample, such as microvesicles; size separation of RNases from the biological sample; denaturation of proteins in the biological sample by various techniques including, but not limited to, generating a particular pH condition, a temperature condition, (e.g., the maintenance of a decreasing or lower temperature), freeze/thaw cycles, and combinations thereof.

[0077] One surprising manifestation of the use of extraction enhancement operations, as described herein, is the ability to detect in an extraction of nucleic acid from microvesicles the existence of significant quantities of ribosomal RNA (rRNA). No prior studies are known to have demonstrated the detection of 18S and 28S rRNA in microvesicle nucleic acid extractions. On the contrary, prior studies suggested that no or little rRNA is present in nucleic acid extracts from microvesicles (Skog et al., 2008; Taylor and Gercel-Taylor, 2008; Valadi et al., 2007).

[0078] In another aspect of this invention, the performance of an extraction enhancement operation will improve the quality of extracted RNA in terms of RNA integrity number (RIN). Designed by Agilent Technologies (<http://www.chem.agilent.com/en-us/products/instruments/lab-on-a-chip/pages/gp14975.aspx>, accessed July 15, 2010), the RNA integrity number (RIN) is the product of a software tool designed to estimate the integrity of total RNA samples. The software automatically assigns an integrity number to an eukaryote total RNA sample. Using this tool, sample integrity is not determined by the ratio of the 18S and 28S ribosomal bands, but by the entire electrophoretic trace of the RNA sample. This includes the presence or absence of degradation products. The assigned RIN is independent of sample concentration, instrument, and analyst, and can serve as a standard for RNA integrity.

[0079] In yet another aspect of this invention, the performance of an extraction enhancement operation will improve the quantity or yield of extracted nucleic acid. For example, using an extraction enhancement operation, as described herein, one may obtain a nucleic acid yield of greater than or equal to 50 pg/ml from a 20 ml low protein biological sample such as urine. Alternatively, one may obtain a nucleic acid yield of greater than or equal to 50 pg/ml from 1 ml of a high protein biological sample, such as serum or plasma.

[0080] Novel high quality nucleic acid extractions obtained by the methods described herein may display a combination of the detection of 18S and 28S rRNA, preferably in a ratio of approximately 1:1 to approximately 1:2; and more preferably, approximately 1:2; a RNA integrity number of greater than or equal to 5 for a low protein biological sample, or greater than or equal to 3 for a high protein biological sample; and a nucleic acid yield of greater than or equal to 50 pg/ml from a 20 ml low protein biological sample or a 1 ml high protein biological sample.

[0081] High quality RNA extractions are highly desirable because RNA degradation can seriously affect downstream assessment of the extracted RNA, such as in gene expression and mRNA analysis, as well as analysis of non-coding RNA such as small RNA and micro RNA. The novel methods described herein enable one to extract high quality nucleic acids from a biological sample such as microvesicles so that an accurate analysis of gene expression and mutational level within the exosomes can be carried out. In one embodiment, for example, when increased concentrations of protease (5X, 10X) are used as an extraction enhancing agent, the amount and integrity of RNA isolated from urinary microvesicles is increased significantly.

[0082] Another aspect of this invention provides methods of extracting high quality small RNA from a biological sample such as urine. Small RNA, such as miRNA is particularly susceptible to degradation and loss during the process of nucleic acid extraction. In the novel methods here disclosed, a high concentration of protease is used to remove or mitigate adverse factors that prevent high quality extraction of small RNAs. In one embodiment, a method to extract nucleic acid, particularly small RNA, uses 25X and 50X protease as extraction enhancing agent and is able to obtain significantly increased amounts of small RNA. As used herein, expressions such as 5X, 10X, 25X and 50X mean 5 times, 10 times, etc. the activity level of protease currently used or recommended in commercially available nucleic acid extraction kits such as the QIAamp MinElute Virus Spin Kit.

[0083] When the adverse factors affecting extraction have been removed or mitigated, nucleic acid molecules can be isolated from a biological sample using any number of procedures that are well-known in the art. Persons of skill will select a particular isolation procedure as being appropriate for the particular biological sample. Examples of methods for extraction are provided in the Examples section herein. In some instances, with some

techniques, it may also be possible to analyze the nucleic acid without extraction from the microvesicle.

[0084] In one embodiment, the extracted nucleic acids, including DNA and/or RNA, are analyzed directly without an amplification step. Direct analysis may be performed with different methods including, but not limited to, nanostring technology. NanoString technology enables identification and quantification of individual target molecules in a biological sample by attaching a color coded fluorescent reporter to each target molecule. This approach is similar to the concept of measuring inventory by scanning barcodes. Reporters can be made with hundreds or even thousands of different codes allowing for highly multiplexed analysis. The technology is described in a publication by Geiss et al. (Geiss et al., 2008) and is incorporated herein by reference for this teaching.

[0085] In another embodiment, it may be beneficial or otherwise desirable to amplify the nucleic acid of the microvesicle prior to analyzing it. Methods of nucleic acid amplification are commonly used and generally known in the art, many examples of which are described herein. If desired, the amplification can be performed such that it is quantitative. Quantitative amplification will allow quantitative determination of relative amounts of the various nucleic acids, to generate a profile as described below.

[0086] In one embodiment, the extracted nucleic acid is RNA. The RNA is then preferably reverse-transcribed into complementary DNA (cDNA) before further amplification. Such reverse transcription may be performed alone or in combination with an amplification step. One example of a method combining reverse transcription and amplification steps is reverse transcription polymerase chain reaction (RT-PCR), which may be further modified to be quantitative, e.g., quantitative RT-PCR as described in US Patent No. 5,639,606, which is incorporated herein by reference for this teaching.

[0087] Nucleic acid amplification methods include, without limitation, polymerase chain reaction (PCR) (US Patent No. 5,219,727) and its variants such as in situ polymerase chain reaction (US Patent No. 5,538,871), quantitative polymerase chain reaction (US Patent No. 5,219,727), nested polymerase chain reaction (US Patent No. 5,556,773), self-sustained sequence replication and its variants (Guatelli et al., 1990), transcriptional amplification system and its variants (Kwoh et al., 1989), Qb Replicase and its variants (Miele et al., 1983), cold-PCR (Li et al., 2008), or any other nucleic acid amplification methods, followed by the detection of the amplified molecules using techniques well known to those of skill in the art. Especially useful are those detection schemes designed for the detection of nucleic acid molecules if such molecules are present in very low numbers. The foregoing references are incorporated herein for their teachings of these methods.

[0088] The analysis of nucleic acids present in the microvesicles is quantitative and/or qualitative. For quantitative analysis, the amounts (expression levels), either relative or absolute, of specific nucleic acids of interest within the microvesicles are measured with methods known in the art (described below). For qualitative analysis, the species of specific nucleic acids of interest within the microvesicles, whether wild type or variants, are identified with methods known in the art.

[0089] The invention disclosed here also includes as a novel composition of matter, a nucleic acid extraction from microvesicles in which 18S and 28S rRNA is detectable in the extraction. Such nucleic acid extractions may be achieved using the novel nucleic acid extraction method disclosed in this invention. A high quality nucleic acid extraction from microvesicles in a biological sample is desirable in many instances. In some instances, a tissue sample is not easily accessible. For example a brain tumor sample can not usually be obtained without brain surgery. Instead, a microvesicle sample from the brain tumor patient serum is easily accessible. In order to analyze nucleic acids in brain tumor cells, it is easier to

analyze nucleic acids in serum microvesicles that are secreted by brain tumor cells.

Therefore, in instances where nucleic acids in microvesicles secreted by tissue cells are used to substitute nucleic acids from tissue cells, it is desirable to obtain high quality nucleic acids which, like those obtained from tissue cells directly, contain detectable quality controls, such as 18S and 28S rRNA. In other instances, high quality small RNA is desirable. Nucleic acid extractions disclosed herein contain such high quality small RNA together with 18S and 28S rRNA. Such high quality small RNA is important for the accurate assessment of nucleic acids for various purposes, e.g., the expression level of a particular miRNA.

[0090] The invention disclosed here further includes a novel, high-quality profile of nucleic acids from microvesicles in a biological sample. Such profiles are generated by analyzing nucleic acid extractions that contain 18S and 28S rRNA. Such profiles may be obtained with the novel methods disclosed herein. High quality nucleic acid profiles are highly desirable for many uses, such as for use as a biomarker for a medical condition or therapy selection. It is desirable in that such profiles are consistent between samples. Such consistency can hardly be achieved without high quality nucleic acid extractions. In one embodiment of this invention, a profile of nucleic acids can be obtained by analyzing nucleic acids in microvesicles that are secreted by those cells of origin. Such microvesicles can be isolated from an easily accessible biological sample, e.g., urine, serum or plasma. Such profiles of nucleic acids may include small RNAs, messenger RNA, microRNA, non-coding RNAs or a combination thereof. In a further embodiment of this invention, such profiles of nucleic acids may be combined with other biomarkers to more accurately achieve certain results.

[0091] The profile of nucleic acids for instance can be a collection of genetic aberrations, which is used herein to refer to the nucleic acid amounts as well as nucleic acid variants within the microvesicles. Specifically, genetic aberrations include, without

limitation, over-expression of a gene (e.g., oncogenes) or a panel of genes, under-expression of a gene (e.g., tumor suppressor genes such as p53 or RB) or a panel of genes, alternative production of splice variants of a gene or a panel of genes, gene copy number variants (CNV) (e.g. DNA double minutes) (Hahn, 1993), nucleic acid modifications (e.g., methylation, acetylation and phosphorylations), single nucleotide polymorphisms (SNPs), chromosomal rearrangements (e.g., inversions, deletions and duplications), and mutations (insertions, deletions, duplications, missense, nonsense, synonymous or any other nucleotide changes) of a gene or a panel of genes, which mutations, in many cases, ultimately affect the activity and function of the gene products, lead to alternative transcriptional splice variants and/or changes of gene expression level.

[0092] The determination of such genetic aberrations can be performed by a variety of techniques known to the skilled practitioner. For example, expression levels of nucleic acids, alternative splicing variants, chromosome rearrangement and gene copy numbers can be determined by microarray analysis (US Patent Nos. 6,913,879, 7,364,848, 7,378,245, 6,893,837 and 6,004,755) and quantitative PCR. Particularly, copy number changes may be detected with the Illumina Infinium II whole genome genotyping assay or Agilent Human Genome CGH Microarray (Stemers et al., 2006). Nucleic acid modifications can be assayed by methods described in, e.g., US Patent No. 7,186,512 and patent publication WO/2003/023065. Particularly, methylation profiles may be determined by Illumina DNA Methylation OMA003 Cancer Panel. SNPs and mutations can be detected by hybridization with allele-specific probes, enzymatic mutation detection, chemical cleavage of mismatched heteroduplex (Cotton et al., 1988), ribonuclease cleavage of mismatched bases (Myers et al., 1985), mass spectrometry (US Patent Nos. 6,994,960, 7,074,563, and 7,198,893), nucleic acid sequencing, single strand conformation polymorphism (SSCP) (Orita et al., 1989), denaturing gradient gel electrophoresis (DGGE)(Fischer and Lerman, 1979a; Fischer and Lerman, 1979b), temperature gradient gel electrophoresis (TGGE) (Fischer and Lerman, 1979a;

Fischer and Lerman, 1979b), restriction fragment length polymorphisms (RFLP) (Kan and Dozy, 1978a; Kan and Dozy, 1978b), oligonucleotide ligation assay (OLA), allele-specific PCR (ASPCR) (US Patent No. 5,639,611), ligation chain reaction (LCR) and its variants (Abravaya et al., 1995; Landegren et al., 1988; Nakazawa et al., 1994), flow-cytometric heteroduplex analysis (WO/2006/113590) and combinations/modifications thereof. Notably, gene expression levels may be determined by the serial analysis of gene expression (SAGE) technique (Velculescu et al., 1995). In general, the methods for analyzing genetic aberrations are reported in numerous publications, not limited to those cited herein, and are available to skilled practitioners. The appropriate method of analysis will depend upon the specific goals of the analysis, the condition/history of the patient, and the specific cancer(s), diseases or other medical conditions to be detected, monitored or treated. The forgoing references are incorporated herein for their teachings of these methods.

[0093] It should be understood that this invention is not limited to the particular methodologies, protocols and reagents, described herein, which may vary. The terminology used herein is for the purpose of describing particular embodiments only, and is not intended to limit the scope of the present invention, which is defined solely by the claims.

[0094] Examples of the presently disclosed subject matter are set forth below. Other features, objects, and advantages of the presently disclosed subject matter will be apparent from the detailed description, figures, examples and claims. Methods, devices, and materials substantially similar or equivalent to those described herein can be used in the practice or testing of the presently disclosed subject matter. Exemplary methods, devices, uses and materials are now described.

Microvesicles in Urine

Example 1: Renal cells contain multivesicular bodies

[0095] To examine whether renal cells shed microvesicles, we used Transmission

Electron Microscopy (TEM) to determine whether renal cells contain multivesicular bodies that can give rise to microvesicles. Rat kidney was fixed by intravascular perfusion with 2.0% glutaraldehyde in 0.1 M sodium cacodylate buffer, pH 7.4 (Electron Microscopy Sciences, PA), and kidney slices were further fixed overnight at 4°C. The sample slices were rinsed in 0.1 M sodium cacodylate buffer, post-fixed in 1.0% osmium tetroxide in cacodylate buffer for 1 h at room temperature, rinsed in buffer again, then rinsed in distilled water (dH₂O) and stained, *en bloc*, in an aqueous solution of 2.0% uranyl acetate for 1 hour at room temperature. The samples were rinsed in distilled water and dehydrated through a graded series of ethanol to 100%. The samples were infiltrated with Epon resin (Ted Pella, CA) by overnight immersion in a 1:1 solution of Epon:ethanol. The following day samples were placed in fresh Epon for several hours and embedded in Epon overnight at 60°C. Thin sections were cut on a Reichert Ultracut E ultramicrotome, collected on formvar-coated grids, stained with uranyl acetate and lead citrate. Samples were examined in a JEOL JEM 1011 transmission electron microscope at 80 kV. Images were collected using an AMT (Advanced Microscopy Techniques, MA) digital imaging system. As shown in **Figure 1**, transmission electron microscope (TEM) images of MVBs are seen in rat renal tissue cells. Multivesicular bodies (MVB) can be identified in various regions of the nephron and collecting duct, including the podocyte, the proximal tubule, thin descending limb, thick ascending limb, collecting duct principal cell, and collecting duct intercalated cell. This demonstrates that exosomes can indeed be released from various regions of the nephron as well as both intercalated and principal cells of the collecting duct.

Example 2: Microvesicles exist in urine

[0096] To examine microvesicles themselves, we examined human urinary microvesicles by TEM. Human urine was obtained under the approved IRB guidelines of the Massachusetts General Hospital. Urine was then pre-processed by a method consisting of three steps: centrifugation of the urine at 300g for 10 min at 4°C, centrifugation of the

supernatant at 17,000g for 20 min at 4°C, and filtration of the supernatant through a 0.8 µm filter (cellulose nitrate membrane filter unit, Nalgene, NY). Alternatively, urine was pre-processed by a one-step filtration directly through a 0.8 µm filter without any pre-centrifugation steps. In either case, the filtrate then underwent ultracentrifugation at 118,000g for 70 min at 4°C, the supernatant was removed and the microvesicle-containing pellet was washed in PBS and re-pelleted at 118,000g for 70 min at 4°C.

[0097] Instead of ultracentrifugation, filtration concentration was also used to isolate microvesicles from pre-processed samples. The filtrate concentrator (100kDa MWCO) (Millipore, MA) was prepared according to the manufacturer's instructions. Pre-processed filtrate was added to the filtration concentrator and centrifuged at 4,000g for 4 min at RT. A 15 ml PBS wash step was included.

[0098] Microvesicle pellets were fixed, 1:1 with 4% paraformaldehyde in dH₂O. Ten (10) µl drops were pipetted onto formvar-coated 200 mesh gold grids and drawn off after one minute. Samples were rinsed 2 times with drops of dH₂O. Aqueous 2.0% phosphotungstic acid (PTA) was applied (10 µl) for 10 sec, drawn off and rinsed once with dH₂O. Samples were examined in a JEOL JEM 1011 transmission electron microscope at 80 kV. Images were collected using an AMT (Advanced Microscopy Techniques, MA) digital imaging system. As shown in **Figure 2**, the pellet was indeed rich in microvesicles. The microvesicles sometimes aggregate together or remain singular in the TEM image.

Improved Methods for Nucleic Acid Extraction from a Biological Sample

Example 3: Ultracentrifugation is replaceable with filtration concentrator for purposes of microvesicle isolation

[0099] We show here that filtration concentrators can yield viable microvesicles for RNA extraction similar to the ultracentrifugation method. We pre-processed 75 ml urine by centrifugation at 300g for 10 minutes at 4°C and 17,000g for 20 minutes at 4°C, and then filtered through a 0.8 µm filter as detailed in Example 2. We then isolated microvesicles via

a 100kDa MWCO filtration concentrator (Millipore, MA) and via ultracentrifugation both with RNase digestion, respectively, and with and without DNase digestion to remove extra-microvesicular nucleic acid contamination. As shown in **Figures 3 and 4**, the ultracentrifugation method and filtration concentration method yielded similar RNA concentrations from the 75 ml urine samples with ultracentrifugation (**Figure 4**) at 410 ± 28 pg/ μ l, and filtration concentrator (**Figure 3**) at 381 ± 47 pg/ μ l (Mean $\pm$ SD). There is no statistically significant difference between the two yields. These data demonstrate that the use of filtration concentrators is a reliable method for isolating urinary microvesicles for RNA analysis.

Example 4: Sample pre-processing with only a 0.8µm pre-filtration step is sufficient for purpose of microvesicle isolation

[00100] Further, we found that the low speed centrifugation steps at 300g and 17,000g could be eliminated because urine pre-processing with just a 0.8 µm pre-filtration step was as effective as methods including the low speed centrifugation steps. As shown in **Figures 5 and 6**, the nucleic acid profile using a method of low speed centrifugation coupled with 0.8 µm pre-filtration (**A**) is the same as the profile using a method of only 0.8 µm pre-filtration (**B**).

Example 5: Nucleic acid extraction from urinary microvesicles with methods that include removal or mitigation of adverse factors

[00101] We used an improved method for nucleic acid extraction from microvesicles. In this method, we removed adverse factors for high quality nucleic acid extractions before breaking microvesicular membranes. As shown in **Figure 7**, urine samples **100** were pre-processed by filtering through a 0.8 µm filter membrane **110**. The microvesicles in the filtrates were then isolated either by ultracentrifugation or by filtration concentration **120**, with details similar to those described in Example 2. The isolated microvesicles were then subjected to RNase and/or DNase digestion to remove nucleic acids not contained inside the microvesicles **130**. Specifically, the microvesicles were resuspended in 1 µl/ml RNase A (DNase and protease free) (Fermentas, MD) in PBS and incubated for 1 hr at 37°C. The samples were re-pelleted at 118,000g for 70 min in PBS. For DNase I digestion the pellet was resuspended in 500 µl PBS and DNase I (RNase free)(Qiagen, CA) diluted in RDD buffer (according to manufacture's instructions) and incubated at room temperature for 10 min. The samples were re-pelleted at 118,000g for 70 min in PBS. For RNase A and DNase I digestion of microvesicles isolated via filtration concentrators, the same concentration of RNase and DNase was used and incubations were carried out in the filtration concentrators. A step of extraction enhancement **140** was then performed, e.g., three resuspension/wash

steps with 15 ml of PBS alone, or coupled with a protease treatment. After microvesicles were isolated, digested with nucleases and treated with protease, nucleic acids were extracted **150**. The RNA extraction was performed using the RNeasy Micro kit (Qiagen, CA) according to the manufacturer's instructions. Briefly, 350 µl RLT buffer (with 10 µl beta-mercaptoethanol per ml RLT) was used to lyse exosomes and 16 µl nuclease-free water was used for elution. The RNeasy Plus Micro kit (Qiagen, CA) is designed to remove genomic DNA (gDNA) and was carried out according to the manufacturer's instructions and eluted in 16 µl nuclease-free water. For small RNA isolation using the RNeasy Micro kit or RNeasy Plus Micro kit, the miRNA isolation method was followed according to the manufacturer's instructions. Isolated RNA was analyzed **160** on a RNA Pico 6000 chip (Agilent, CA) using a Agilent BioAnalyzer (Agilent, CA) which generated an electrophoretic profile and corresponding 'pseudo gel' of the sample.

[00102] As shown in **Figures 8 and 9**, the quality (in terms of yield and integrity) of RNA extraction from urine microvesicles increases as more protease is used to treat microvesicles before breaking the membrane of microvesicles. In **Figure 8**, nucleic acids from microvesicles in 20 ml urine were extracted using the above improved method except that the RNA extraction was performed using the Qiagen Qiamin elute virus spin kit. The urine sample was concentrated with filtration concentration and eluted in 200 µl PBS. Here, we define 1X protease as 0.027 AU; 5X protease as 0.135 AU; 10X protease as 0.27 AU; 25X protease as 0.675 AU; and 50X as 1.35 AU. 18S and 28S rRNA peaks of greater integrity were observed when the concentration of protease was increased from 5X (**A**) to 10X (**B**). Likewise, as shown in **Figure 9**, at higher concentrations of protease, 25X (**A**) and 50X (**B**), we observed 18S and 28S rRNA of higher integrity, in addition to increased small/miRNA levels. These data suggest that the addition of protease can increase the yield and integrity of 18S and 28S rRNA as well as small RNA and microRNA. We suspect that the effect of protease may be due to its ability to digest away RNases and other inhibitory

factors.

[00103] The addition of a step of washing microvesicles multiple times also dramatically improves the quality of nucleic acids extracted from urinary microvesicles. The washing step can effectively remove adverse factors that prevent high quality nucleic acid extraction from urinary microvesicles. Urine samples of 20 ml each are used for four groups of nucleic acid extraction tests following the above method with except some modifications. For group 1, isolated microvesicles were directly used for nucleic acid extraction without any intervening steps. For group 2, microvesicles were treated with RNase inhibitors before nucleic acid extraction. For group 3, microvesicles were washed without any RNase inhibitor treatment before nucleic acid extraction. For group 4, microvesicles were washed and treated with RNase inhibitors. As shown in **Figure 38**, for group 1 tests, the quality of the extracted nucleic acids was very poor with RIN of 3.63 ± 2.3 and RNA concentration of 101.3 ± 27.6 pg/ μ l. For group 2 tests (**Figure 39**), the quality of the extracted nucleic acids was roughly similar to that in group 1 tests with RIN of 1.83 ± 2.2 and RNA concentration of 101.6 ± 88 pg/ μ l. For group 3 tests (**Figure 40**), the quality of the extracted nucleic acids was improved dramatically with RIN of 9.2 ± 0.0 and RNA concentration of 347.7 ± 97.7 pg/ μ l. For group 4 tests (**Figure 41**), the quality of the extracted nucleic acids was similar to that in group 3 with RIN of 7.43 ± 0.2 and RNA concentration of 346.3 ± 32.7 pg/ μ l. These data showed that without washing steps, the extraction quality from microvesicles were inconsistent, with a relatively higher variation than those extractions where microvesicles had been washed before nucleic acid extraction.

Example 6: Use of RNase inhibitors for nucleic acid extraction from serum microvesicles

[00104] With the above improved method, high quality nucleic acid extractions can also be obtained from serum microvesicles. Here, we obtained serum from both melanoma and normal patient sera and used RNase inhibitor cocktail SUPERase-In™ (Ambion, Inc.) to treat microvesicle pellets by resuspension. In one batch of tests, we isolated microvesicles

from four duplicates of 1 ml melanoma serum samples and treated the microvesicle pellets with 1.6 units SUPERase-In/ μ l at a final concentration. The microvesicle isolation method was ultracentrifugation and the microvesicle pellets were treated with DNase for 20 minutes at room temperature. As shown in **Figures 10-13**, the quality of RNA extraction from the four melanoma serum samples was low and inconsistent, with the RNA yield being 543 pg/ μ l, 607 pg/ μ l, 1084 pg/ μ l, 1090 pg/ μ l, and the RNA integrity assessed by the 28s/18s ratio being 1.7, 1.8, 1.3, and 0.6, respectively. In another batch of tests, we isolated microvesicles from two duplicates of 1 ml melanoma serum samples and treated the microvesicle pellets with 3.2 units SUPERase-In μ /l at a final concentration. As shown in **Figures 14 and 15**, the quality of RNA extraction from the two melanoma serum samples treated with 3.2 units SUPERase-In/ μ l was generally better than the quality of RNA extraction from those treated with 1.6 units SUPERase-In/ μ l. The RNA yield for the two melanoma serum samples is 3433pg/ μ l and 781pg/ μ l and the 28S/18S ratio is 1.4 and 1.5, respectively.

[00105] Further, we tested four duplicates of 1 ml normal serum samples at 1.6 units SUPERase-In/ μ l and 2 duplicates of 1 ml normal serum samples at 3.2 SUPERase-In/ μ l. As shown in **Figures 16-19**, the quality of RNA extraction at 1.6 units SUPERase-In/ μ l is low with the RNA yield being 995 pg/ μ l, 1257 pg/ μ l, 1027 pg/ μ l, and 1206 pg/ μ l, and the 28S/18S ratio being 1.3, 1.6, 1.6, 1.8, respectively. In contrast, as shown in **Figures 20 and 21**, the quality of RNA extraction at 3.2 units SUPERase-In/ μ l increases with the RNA yield being 579 pg/ μ l and 952 pg/ μ l, and the 28S/18S ratio being 1.6 and 2.3, respectively.

Example 7: Use of extraction enhancement agents for nucleic acid extraction from a biological sample

[00106] In Examples 3 and 4, our test results suggest that treatment with extraction enhancers can increase the quality of RNA extraction from microvesicles. It is expected that such extraction enhancers will have similar effects on other biological samples. As shown in **Figure 22**, a novel method of nucleic acid extraction in this invention will require a step of performing an extraction enhancement operation on the biological sample. Such method may be exemplified in the following conceived nucleic acid extraction experiment. A doctor prescribes a test of a tumor biomarker for a patient. A 5 ml blood is then drawn from the patient. The blood sample **200** is sometimes pre-processed to get the blood serum. An enhancement operation **210** is then performed, e.g., an appropriate amount of extraction enhancer is added to the serum and the mixture is incubated for 30 minutes at 37°C. Nucleic acids from the treated serum are then extracted using regular extraction methods such as detailed in Example 5 **220** and analyzed using Agilent BioAnalyzer **230**. Such extraction is expected to produce high quality nucleic acids from the biological sample.

Nucleic Acids From Urinary Microvesicles As Biomarkers

Example 8: Urinary microvesicles are contaminated by free, extra-microvesicle, non-cellular DNA

[00107] We separated a urine sample into two 25 ml duplicate samples and isolated microvesicles from the two sub-samples by differential centrifugation as detailed above. In one sub-sample, we treated the microvesicles with DNase and extracted nucleic acids from the treated microvesicles as detailed above. In another sub-sample, we did not treat the microvesicles with DNase and extracted nucleic acids from the untreated microvesicles. As shown in **Figure 23**, free, extra-microvesicle, non-cellular DNA contaminated isolated urinary microvesicles. When RNeasy micro kit was used for the nucleic acid extraction (**Figure 23 A and B**), the result showed that more nucleic acids were seen in the untreated

sample (A) than the treated sample (B) since the peak in (A) was generally higher than the peak in (B).

[00108] In another test, we performed a similar test except that serum samples were used instead of urine samples. As shown in **Figure 24**, free, extra-microvesicle, non-cellular DNA also contaminated the isolated serum microvesicles. More nucleic acids were seen in the DNase untreated sample (A) than the DNase treated sample (B) since the peak in (A) was generally higher than the peak in (B). Similarly, when MirVana kit was used for the nucleic acid extraction, as shown in Figure 23 (C) and (D), the result also showed that more nucleic acids were seen in the untreated sample (C) than the treated sample (D) since the peak in (C) was generally higher than the peak in (D). The extra nucleic acids from the untreated sample were likely from DNase susceptible “apoptotic bodies” because DNase susceptible “apoptotic bodies”-like ladders were seen as shown in the pseudo gel in **Figure 24 C**. In both the urine and the serum samples, the amount of the free, extra-microvesicle, non-cellular DNA varied between subjects but the size of this DNA was in the range of approximately 25 to 1500 base pairs.

[00109] *Example 9: Urinary microvesicles are mostly not contaminated by free, extra-microvesicle, non-cellular RNA*

[00110] We separated a urine sample into two 25 ml duplicate samples and isolated microvesicles from the two sub-samples by differential centrifugation as detailed above. In one sub-sample, we treated the microvesicles with RNase and extracted nucleic acids from the treated microvesicles as detailed above. In another sub-sample, we did not treat the microvesicles with RNase and extracted nucleic acids from the untreated microvesicles. As shown in **Figure 25**, almost no free, extra-microvesicle, non-cellular RNA contaminated the isolated microvesicles. The curve of the RNase untreated sample (A) mostly overlapped with the curve of the RNase treated sample (B), suggesting there is no free extra-microvesicle, non-cellular RNA associated with the isolated microvesicles. This may be due to the

presence of ribonucleases in urine.

Example 10: Nucleic acid profiles are similar in urinary microvesicles and renal cells measured by Agilent BioAnalyzer.

[00111] We extracted nucleic acids from both urinary microvesicles and renal (kidney) tissues and compared their profiles. The method of extraction from urinary microvesicles was as detailed in Example 5. The rat kidney samples were processed via the RNeasy Mini kit and the RNeasy Plus kit. To determine the amount of small RNAs in the rat kidney sample, they were also processed by both kits using the miRNA isolation method according to the manufacturer's instructions.

[00112] As shown in **Figure 26**, their profiles (**A**-kidney, **B**-microvesicle) were very similar including the presence and integrity of the 18S and 28S rRNA peaks. Such 18S and 28S rRNA peaks had not been seen in previously reported serum-derived or cell culture media-derived microvesicles.

[00113] In addition to the similarities in rRNA peaks, urinary microvesicles also contained similar small RNA profiles to those obtained from renal cells. As shown in **Figure 27**, both urinary microvesicles (**B**) and renal tissue (**A**) contained small RNAs (about 25-200 base pairs) and shared similar patterns.

[00114] These data suggest that using the novel nucleic acid extraction method disclosed in this invention, the profiles in urinary microvesicles may be used to examine the profiles in the renal cells from which the microvesicles originated.

Example 11: RNA profiles in urinary microvesicles are different from those from whole urine.

[00115] We discovered that RNA profiles in urinary microvesicles are different from those from whole urine. We used 75 ml duplicate urine samples for the tests. RNA was isolated from urinary microvesicles by first pre-processing the urine by 300g for 10 min at 4°C, centrifugation of the supernatant at 17,000g for 20 min at 4°C, and filtration of the

supernatant through a 0.8 µm filter (cellulose nitrate membrane filter unit, Nalgene, NY), followed by the steps as detailed in Example 5. RNA from whole urine was isolated using the ZR urine RNA isolation kit (Zymo Research, CA) according to the manufacturer's instructions. To remove DNA from the Zymo processed sample, the eluted RNA was resuspended in 350 µl RLT buffer and processed via the RNeasy Plus Micro kit, which used DNase to eliminate associated DNA, and eluted in 16 µl nuclease free water.

[00116] As shown in **Figure 28**, a large amount of nucleic acid could be isolated using the ZR urine RNA isolation kit when no DNase was used (**A**). However, the profile appeared broad and lacked 18S and 28S rRNA peaks. Further, the profile changed significantly (**B**) when DNase was used, suggesting most of the extract was DNA in nature. In contrast, as shown in **Figure 29**, the RNA profile from microvesicles from the same urine sample was generally very different from the profile from the whole urine extraction. In the microvesicle profile, there were 18S and 28S peaks. In addition, RNA from microvesicles was more abundant than that from the whole urine. DNase digestion of the extractions from microvesicles did not affect the rRNA peak significantly when we compared the profile without DNase treatment (**A**) to the profile with DNase treatment (**B**). The RNA profiles from the 300g pellets (**Figure 30**) and the 17,000g pellets (**Figure 31**) were similar to that from the whole urine extraction. In both of these profiles, the peaks decreased substantially after DNase treatment when we compared the profile without DNase treatment (**A**) to the profile with DNase treatment (**B**). These data suggested that DNA was the predominant species in the extraction, and no 18S and 28S rRNA peaks were detectable. Therefore, together with the data in Example 10, RNA profiles from urinary microvesicles is more similar to renal cell profiles than to profiles from whole urine. Further, the integrity of RNA extraction from microvesicles was at least 10 times better than that from whole urine.

Example 12: Urinary microvesicles contain both RNA and DNA.

[00117] We determined whether urinary microvesicles contained RNA, DNA, or both

by treating the pellets first with both RNase and DNase to remove free, extra-microvesicle, non-cellular contaminations followed by RNase and/or DNase digestion of intra-microvesicle nucleic acids during column based nucleic acid isolation. RNase digestion (**B**) almost completely abolished the nucleic acid profile (**Figure 32**) compared to that without RNase digestion (**A**). These data suggest that RNA represents the most abundant nucleic acid within microvesicles. As shown in **Figure 33**, after on-column digestion of the RNase treated samples with DNase (**B**), the peak just after 20s is reduced after further DNase digestion inside in comparison with the peak before further DNase digestion (**A**). This reduction demonstrated that a small amount of DNase-digestible material was present within microvesicles, probably DNA.

Example 13: Urinary microvesicles contain mRNA transcripts encoding specific genes from various regions of the nephron and collecting duct.

[00118] As shown in Example 10, nucleic acid profiles are similar in urinary microvesicles and renal cells measured by Agilent BioAnalyzer. Here we further show that microvesicles contain mRNA transcripts encoding specific genes from various regions of the nephron and collecting duct. Urinary microvesicles were isolated from 200 ml urine from four human subjects (23 to 32 years of age) and were digested with RNase and DNase prior to exosome lysis and RNA extraction as detailed in Example 5. The extracted RNA underwent two rounds of mRNA amplification using RiboAmp (Molecular Devices, CA). For the riboamplification for the first round of the *in vitro* transcription step samples were incubated at 42°C for 4 hours and for the second *in vitro* transcription step samples were incubated at 42°C for 6 hours. Amplified RNA was denatured for 5 minutes at 65°C and subjected to first strand cDNA synthesis as described in the Qiagen Omniscript protocol (Qiagen, CA). Both GAPDH and beta-actin genes were identified in all samples (**Figure 34A**). We examined 15 transcripts characteristic of various regions of the nephron and collecting duct (**Figure 34B**). These included proteins and receptors implicated in various

renal diseases including podocin from the glomerulus, cubilin from the proximal tubule and aquaporin 2 from the collecting duct.

[00119] For human samples, the PCR primers used were: ACTB UTR, forward 5'-GAAGTCCCTTGCCATCCTAA-3', reverse 5'-GCTATCACCTCCCCTGTGTG-3'; GAPDH EX, forward 5'-ACACCCACTCCTCCACCTTT-3', reverse 5'-TGCTGTAGCCAAATTCGTTG-3'; NPHS2 UTR, forward 5'-AACTTGGTTCAGATGTCCCTTT-3', reverse 5'-CAATGATAGGTGCTTGTAGGAAG-3'; LGALS1 EX, forward 5'-GGAAGTGTTGCAGAGGTGTG-3', reverse 5'-TTGATGGCCTCCAGGTTG-3'; HSPG2 UTR, 5'-AAGGCAGGACTCACGACTGA-3', reverse 5'-ATGGCACTTGAGCTGGATCT-3'; CUBN EX, forward 5'-CAGCTCTCCATCCTCTGGAC-3', reverse 5'-CCGTGCATAATCAGCATGAA-3'; LRP2 EX, forward 5'-CAAAATGGAATCTCTTCAAACG-3', reverse 5'-GTCGCAGCAACACTTTCCTT-3'; AQP1 UTR, forward 5'-TTACGCAGGTATTTAGAAGCAGAG-3', reverse 5'-AGGGAATGGAGAAGAGAGTGTG-3'; CA4 UTR, forward 5'-ATGATGGCTCACTTCTGCAC-3', reverse 5'-TCATGCCTAAAGTCCCACCT-3'; CLCN5 EX, forward 5'-GTGCCTGGTTACACACAACG-3', reverse 5'-AGGATCTTGGTTCGCCATCT-3'; BDKRB1 UTR, forward 5'-GTGGTTGCCTTCCTGGTCT-3', reverse 5'-ATGAAGTCCTCCCAAAGCA-3'; CALCR UTR, forward 5'-ATTTTGCCACTGCCTTTCAG-3', reverse 5'-ATTTTCTCTGGGTGCGCTAA-3'; SCNN1D UTR, forward 5'-GCGGTGATGTACCCATGCT-3', reverse 5'-CTGAGGTGGCTAGGCTTGA-3'; SLC12A3 EX, forward 5'-AGAACAGAGTCAAGTCCCTTCG-3', reverse 5'-TATGGGCAAAGTGATGACGA-3'; AQP2 UTR, forward 5'-GCAGTTCCTGGCATCTCTTG-3', reverse 5'-GCCTTTGTCCTTCCCTAACC-3'; ATP6V1B1 EX, forward 5'-AGGCAGTAGTTGGGGAGGAG-3', reverse 5'-

CGAGCGGTTCTCGTAGGG-3'; SLC12A1 EX, forward 5'-

CAGATGCAGAACTGGAAGCA-3', reverse 5'-GGAAGGCTCAGGACAATGAG-3'.

“UTR” refers to primers designed in the UTR and “EX” refers primers designed across exons. The PCR protocol was 5 min at 94°C; 40 s at 94°C; 30 s at 55°C; 1 min at 65°C for 30 cycles; and 68°C for 4 min. For mouse samples the primers used were: AQP2: forward 5'-GCCACCTCCTTGGGATCTATT-3', reverse 5'-TCATCAAACCTTGCCAGTGACAAC-3'; V-ATPase B1 subunit: forward 5'-CTGGCACTGACCACGGCTGAG -3', reverse 5'-CCAGCCTGTGACTGAGCCCTG -3'. The PCR protocol was 5 min at 94°C; 40 s at 94°C, 30 s at 55°C, 1 min at 65°C for 30 cycles; and 68°C for 4 min.

[00120] As shown in **Figure 34, Panel A**, RiboAmp amplified mRNA transcripts for beta-actin and GAPDH were readily detectable in the BioAnalyzer generated pseudo gel in urinary microvesicles from the four human subjects. For clarification purpose, the six regions of the nephron and collecting duct are shown in **Figure 34, Panel B**. As a result of RT-PCR analysis of RiboAmped mRNA from urinary exosomes, the following transcripts in the six regions are also readily detectable: region 1 Glomerulus: NPHS2 – podocin, LGALS1 – Galectin-1 , and HSPG2 – heparan sulfate proteoglycan (**Figure 35**); region 2 Proximal Tubule: CUBN – cubilin, LRP2 – megalin, AQP1 – aquaporin 1, CA4 – carbonic anhydrase 4, and CLCN5 – chloride channel protein 5 (**Figure 35**); region 3 Thin Descending Limb: BDKRB1 – bradykinin B1 receptor (**Figure 36**); region 4 Medullary Thick Ascending Limb: CALCR – calcitonin receptor, and SCNN1D - amiloride-sensitive sodium channel subunit delta (**Figure 36**); region 5 Distal Convolute Tubule: SLC12A3 – thiazide-sensitive sodium-chloride cotransporter (**Figure 36**); region 6 Collecting Ducts: AQP2 – aquaporin 2, ATP6V1B1 – vATPase B1 subunit, and SLC12A1 – Kidney-specific Na-K-Cl symporter (**Figure 36**).

[00121] Therefore, mRNA transcripts from all renal regions examined could be identified, suggesting that microvesicles containing mRNA are released from all regions of

the nephron and collecting duct, and microvesicles can be a novel non-invasive source of nucleic acid biomarkers for renal diseases.

Example 14: Some mRNA transcripts inside urinary microvesicles are specific to renal cells

[00122] If nucleic acids in microvesicles are used to non-invasively examine renal genes in diseases, the transcripts in microvesicles should be specific to renal cells. Here, we show that mRNA transcripts are specific to renal cells. We used knockout mice in which the V-ATPase B1 subunit is absent. The absence of V-ATPase B1 subunit leads to renal acidosis in the mice (*Finberg KE, Wagner CA, Bailey MA, et al., The B1-subunit of the H(+) ATPase is required for maximal urinary acidification. Proc Natl Acad Sci USA 102:13616-13621, 2005*).

[00123] All animal experiments were carried out in accordance with approved animal ethics guidelines at the Massachusetts General Hospital. V-ATPase B1 subunit knockout animals have been described (*Finberg KE, Wagner CA, Bailey MA, et al. The B1-subunit of the H(+) ATPase is required for maximal urinary acidification. Proc Natl Acad Sci USA 102:13616-13621, 2005*). For urine collection, animals were caged in metabolic cages in groups of two (n = 4 animals per group) over a period of 72 hours (sufficient RNA can also be obtained by caging one animal per cage, and urine was collected for microvesicle isolation and analysis as described above for human urine. For kidney extraction, animals were anesthetized using pentobarbital sodium (Nembutal) (Abbott Laboratories, IL) (65 mg/kg body weight i.p.), and kidneys immediately removed and frozen in liquid nitrogen. Using a pestle and mortar in a liquid nitrogen bath the frozen kidney was ground up, resuspended in RNeasy lysis buffer (Qiagen, CA) and stored in 1 ml aliquots at -80°C. For RNA extraction, an aliquot was thawed on ice and 50 µl lysed in 350 µl RLT buffer (with 10 µl beta-mercaptoethanol per ml RLT). Mouse kidney samples were processed via the RNeasy Mini kit (Qiagen, CA) with the inclusion of the DNA digestion step.

[00124] For real time PCR analysis, RNA extracted from mouse urinary microvesicles

was denatured for 5 minutes at 65 °C and subjected to first strand cDNA synthesis as described in the Qiagen Sensiscript protocol (Qiagen, MD). For the Sensiscript reverse transcription oligo-dT primers were used at a final concentration of 1µM (Applied Biosystems, CA). The resulting cDNA was used in the TaqMan PreAmp Master Mix Kit according to manufactures guide using 14 preamplification cycles (Applied Biosystems, CA). The preamplification product was then diluted 1:20 with 1X TE buffer (Promega, WI). The resulting cDNA was then used as a template for real-time PCR according to Taqman Preamplification guide (Applied Biosystems, CA). Mouse kidney RNA concentration was measured on a SmartSpec 3000 (Bio-Rad, CA) and all samples were diluted to 90 ng/µl. Mouse kidney RNA was denatured for 5 minutes at 65 °C and subjected to first strand cDNA synthesis as described in the Qiagen Omniscript protocol (Qiagen, MD). In the Omniscript reverse transcription oligo-dT primers were used at a final concentration of 1µM (Applied Biosystems, CA) and 1 µl of the resulting cDNA was then used per well in the subsequent real-time PCR reaction. The real-time PCR reaction was carried out using TaqMan Gene Expression Master Mix and Expression Assays (Mouse GAPD Part Number 4352339E and mouse Atp6v1b2 assay id Mm00431996_mH) on an ABI 7300 Real Time PCR System (Applied Biosystems, CA).

[00125] We extracted RNA from kidney tissues as well as from urinary microvesicles from the knockout mice. We examined the expression of the V-ATPase B1 subunit and aquaporin 2 (AQP2) mRNA using RT-PCR. As shown **Figure 37, Panel A**, V-ATPase B1 subunit transcript was not detected in both the kidney and urinary microvesicle samples from double mutant mice (B1^{-/-}), which is consistent with the fact that V-ATPase B1 subunit gene was knocked out in these mice. In contrast, V-ATPase B1 subunit transcript was present in the kidney and microvesicle samples from the wild-type mice (B1^{+/+}). AQP2 mRNA was readily detected in both the kidney and the microvesicle sample from mice with both the B1

knockout or wild-type mice, which is expected because the V-ATPase B1 subunit deletion does not affect the expression of AQP2. Further, as shown in **Figure 37, Panel B**, the expression level of V-ATPase B2 subunit in microvesicles from the B1 knockout was not statistically different from the level in microvesicles from the wild-type mice. Such was also true for the expression level of V-ATPase B2 subunit in kidney cell from the knockout mice in comparison with the level in kidney cells from the wild-type mice. Therefore, transcripts present in kidney cells can be detected in urinary microvesicles secreted by the kidney cells, and transcripts absent in kidney cells can not be detected in urinary microvesicles secreted by the kidney cell. Accordingly, transcripts in urinary microvesicles are specific to renal cells and are noninvasive biomarkers for renal cells transcripts.

Example 15: Urinary microvesicles contain non-coding RNA transcripts

[00126] Urinary microvesicles were isolated and nucleic acids were extracted according to the above method detailed in Example 5. We performed a deep-sequencing of urinary microvesicle RNAs and found that there were random areas on certain chromosomes that exhibited extreme transcription. When plotted transcript number versus position on the chromosome, these transcripts appeared as “Spikes.” These transcripts were more abundantly expressed than well-know endogenous markers such as GAPDH or actin, and were generally in non-coding regions of the chromosome. The relatively high expression levels of these spike sequences suggest that these sequences may also serve important roles in chromosome activation and cellular regulation.

[00127] We identified 29 regions where there were more than 500 spikes. The 29 regions are shown in **Figure 42** and correspond to **SEQ ID NOS. 1-29**. The plotted spikes in these 29 regions are shown in **Figures 45-73**. PCR analysis of the sequences of the most highly expressed spike transcripts demonstrated that they were indeed present within both human urinary microvesicles and human kidney cells, suggesting that these sequences were

not an artifact of deep sequencing. The primers used to amplify the 10 such spike abundant regions are shown in **Figure 43**. PCR was performed according to the following program: initial denaturing at 95°C for 8 minutes; 30 cycles of three steps of denaturing at 95°C for 40 seconds, annealing at 55°C for 30 seconds, and elongation at 65°C for 1 minute; final elongation at 68 °C for 5 minutes; and on hold at 4°C before BioAnalyzer analysis of the reaction. As shown in **Figure 44**, the amplification of each of these 10 regions gave positive results using templates in both human urinary microvesicles (**A**) and human kidney cells (**B**), suggesting that these spike transcripts were indeed present within microvesicles and human kidney cells.

[00128] These abundant spike transcripts can be used to assess the quality of an nucleic acid extraction from a biological sample. For example, the amount of any of the spike transcripts can be used to assess the quality of nucleic acids from urinary microvesicles in place of common markers such as GAPDH or ACTIN polynucleotide molecules. The amount of GAPDH or ACTIN RNA in urinary microvesicles was so low that an extra-amplification step, *e.g.*, a RiboAMP, was required for measuring their amount. In contrast, the amount of any one of the spike transcripts was so high that no extra-amplification step was necessary. Therefore, the use of these spike transcripts can make the assessment of nucleic acid extraction quality more efficient and simpler. Hence, another aspect of the inventions described herein is a novel method of assessing the quality of a nucleic acid extraction from a biological sample, *e.g.*, a human urine sample. The method can be accomplished by extracting nucleic acids from a biological sample, measuring the amount of any of the spike transcripts, and compare the amount to a standard that has been establish for the particular biological sample. The establishment of such standard can be, for example, an average amount of such spike transcript extracted from 10 normal human urine samples performed by an experienced biotechnology professional.

[00129] While the present invention has been disclosed with reference to certain embodiments, numerous modifications, alterations, and changes to the described embodiments are possible without departing from the sphere and scope of the present invention, as defined in the appended claims. Accordingly, it is intended that the present invention not be limited to the described embodiments, but that it has the full scope defined by the language of the following claims, and equivalents thereof.

CLAIMS

1. A method of obtaining and analyzing RNA from a urine sample, comprising the steps of:
 - (a) obtaining a urine sample and pre-processing the urine sample by filtration through a 0.8 μ m filter;
 - (b) obtaining a microvesicle fraction from the pre-processed urine sample by ultracentrifugation or filtration concentration;
 - (c) washing the microvesicle fraction;
 - (d) extracting RNA from the microvesicle fraction;
 - (e) measuring the quality of the RNA from the microvesicle fraction by determining the quantity of 18S and 28S rRNA in the extraction for the purpose of evaluating the quality of the RNA extraction, where detection of 18S and 28S rRNA in the RNA extraction indicates that the RNA extraction is high yield and/or high integrity; and
 - (f) analyzing one or more RNAs from the RNA extraction of step e) which has been evaluated as high yield and/or high integrity.
2. A method according to Claim 1, in which the microvesicle fraction is obtained by filtration concentration.
3. A method according to Claim 2, in which the filtration concentration comprises passing the urine sample through a filter having a pore size of less than or equal to 0.8 μ m.
4. A method according to any of Claims 1, 2 or 3, in which the urine sample or microvesicle fraction is treated with a ribonuclease, deoxyribonuclease, or a combination thereof, prior to performance of the washing in step (c).
5. A method according to any preceding claim, in which step (c) comprises the addition of an RNase inhibitor, prior to extracting RNA.
6. A method according to Claim 5, in which the RNase inhibitor has a concentration of greater than [1X] concentration; alternatively, greater than or equal to [5X] concentration; alternatively, greater than or equal to [10X] concentration; alternatively, greater than or equal to [25X] concentration; and alternatively, greater than or equal to [50X] concentration.

7. A method according to Claim 5 or 6, in which the RNase inhibitor is a protease.
8. A method according to any preceding claim, further comprising determining a quantitative ratio of 18S rRNA to 28S rRNA in the extraction.
9. A method according to Claim 8, in which the quantitative ratio of 18S rRNA to 28S
5 rRNA is within the range of approximately 1:1 to approximately 1:2.
10. A method according to Claim 8 or 9, in which the quantitative ratio of 18S rRNA to 28S rRNA is approximately 1:2.
11. A method according to Claim 4 comprising:
treating the microvesicle fraction with DNase to eliminate all or substantially all of any
10 DNA located outside of or on the surface of the microvesicles in the fraction; extracting RNA from the sample; and analyzing the extracted RNA.
