

SPECIFICATION

CELL CULTURING SCAFFOLDING MATERIAL AND CELL CULTURING
VESSEL

5 **TECHNICAL FIELD**

[0001]

The present invention relates to a cell culture
scaffold material used for culturing cells. Also, the
present invention relates to a cell culture vessel using
10 the cell culture scaffold material.

BACKGROUND ART

[0002]

Cells of animals such as human, mouse, rat, pig, cow
15 and monkey are used in research and development in academic
fields, drug discovery fields, regenerative medicine fields,
and the like. As a scaffold material used for culturing
animal cells, adhesive proteins such as laminin and
vitronectin, and natural polymer materials such as matrigel
20 derived from mouse sarcoma are used. By using a natural
polymer material as a scaffold material, a domain having a
cell-adhesive amino acid sequence (such as Arg-Gly-Asp) of
laminin, vitronectin or the like and an integrin on a cell
surface are bound, the cells adhere well to the scaffold
25 material, and the cells proliferate well.

[0003]

Moreover, Patent Document 1 below discloses a protein containing a repeating structure and a cell adhesion sequence such as RGD sequence. This protein has a structure in which a specific Ala-rich site and a specific Ala-non-rich site are linked as the repeating structure. Further, Patent Document 1 describes that a material containing this protein can be used as a cell scaffold material.

10 [0004]

Furthermore, scaffold materials using synthetic resins are also known as shown in Patent Documents 2 to 5 below.

[0005]

15 Patent Document 2 below discloses a cell culture carrier composed of a molded product made of a polyvinyl acetal compound or a molded product made of the polyvinyl acetal compound and a water-soluble polysaccharide, the polyvinyl acetal compound having a degree of acetalization of 20 to 60 mol%.

20 [0006]

In addition, Patent Document 3 below discloses a composition (scaffold material) containing a first fiber polymer scaffolding, in which the fibers of the first fiber

polymer scaffolding are aligned. An aliphatic polyester and the like are used as the material of this fiber polymer.

[0007]

Further, Patent Document 4 below discloses a cell
5 culture method for maintaining an undifferentiated state of pluripotent stem cells, including culturing the pluripotent stem cells on an incubator having a surface coated with a polyrotaxan block copolymer.

[0008]

10 Furthermore, Patent Document 5 below discloses a cell culture product comprising a substrate having a surface, a hydrophilic copolymer layer provided on the surface of the substrate, and a plurality of peptide chains bound to a surface of the hydrophilic copolymer layer, respectively.
15 The hydrophilic copolymer layer is a layer copolymerized with a plurality of polyvinyl alcohol units, a plurality of polyvinyl alcohol derivative units, and a plurality of carboxylic acid group-containing units.

SUMMARY OF THE INVENTION

5 PROBLEMS TO BE SOLVED BY THE INVENTION

[0010]

By using a natural polymer material as a scaffold material, cells after seeding proliferate well and pseudopodia extends well. However, natural polymer materials are expensive, have large variations between lots because they are naturally derived substances, or have safety concerns due to animal-derived components. Further, even when a polypeptide with a cell adhesion sequence such as RGD sequence as described in Patent Document 1 is used as a scaffold material, variation in cell adhesion and cell proliferation may occur depending on amino acid sequences other than the cell adhesion sequence.

[0011]

On the other hand, the scaffold materials using synthetic resins as described in Patent Documents 2 to 5 are inexpensive, have less variation between lots and are excellent in safety, in comparison to scaffold materials using natural polymer materials. However, the conventional scaffold materials using synthetic resins as described in Patent Documents 2 to 4 have a problem that cell

proliferation is low. In addition, pseudopodia do not extend sufficiently with the conventional scaffold materials using synthetic resins. Further, although the scaffold material described in Patent Document 5 can enhance the cell proliferation to some extent, it has high hydrophilicity, so that the scaffold material is immersed or swollen in a liquid medium, and the cell proliferation may decrease.

[0012]

10 An object of the present invention is to provide a cell culture scaffold material having excellent extensibility of pseudopodia and excellent cell proliferation. Also, an object of the present invention is to provide a cell culture vessel using the cell culture
15 scaffold material.

MEANS FOR SOLVING THE PROBLEMS

[0013]

According to a broad aspect of the present invention,
20 there is provided a cell culture scaffold material containing a peptide-conjugated polyvinyl alcohol derivative having a polyvinyl alcohol derivative portion and a peptide portion, which has a hydroxyl value of 1,100 mgKOH/g or less.

25 [0014]

According to a broad aspect of the present invention, there is provided a cell culture scaffold material, comprising a peptide-conjugated polyvinyl alcohol derivative having a polyvinyl alcohol derivative portion
5 and a peptide portion, in which the peptide-conjugated polyvinyl alcohol derivative has a hydroxyl value of 1,100 mgKOH/g or less.

[0015]

In a specific aspect of the cell culture scaffold
10 material according to the present invention, the peptide portion has a cell-adhesive amino acid sequence.

[0016]

In another specific aspect of the cell culture scaffold material according to the present invention, the
15 cell-adhesive amino acid sequence has at least an RGD sequence, a YIGSR sequence, or a PDSGR sequence.

[0017]

In still another specific aspect of the cell culture scaffold material according to the present invention, the
20 cell-adhesive amino acid sequence has at least an RGD sequence represented by Formula (1) below:

[0018]

Arg-Gly-Asp-X ... Formula (1)

[0019]

In Formula (1) above, X represents Gly, Ala, Val, Ser, Thr, Phe, Met, Pro, or Asn.

[0020]

In still another specific aspect of the cell culture
5 scaffold material according to the present invention, the peptide portion is composed of 3 or more and 10 or less amino acids.

[0021]

In still another specific aspect of the cell culture
10 scaffold material according to the present invention, the polyvinyl alcohol derivative portion and the peptide portion are bound via a linker portion.

[0022]

In still another specific aspect of the cell culture
15 scaffold material according to the present invention, the peptide-conjugated polyvinyl alcohol derivative is a peptide-conjugated polyvinyl acetal resin having a polyvinyl acetal resin portion and the peptide portion.

[0023]

20 According to a broad aspect of the present invention, there is provided a cell culture vessel including a vessel body and the above-mentioned cell culture scaffold material, in which the cell culture scaffold material is arranged on a surface of the vessel body.

25

EFFECT OF THE INVENTION

[0024]

According to the present invention, it is possible to provide a cell culture scaffold material and a cell culture
5 vessel, having excellent extensibility of pseudopodia and excellent cell proliferation.

BRIEF DESCRIPTION OF DRAWINGS

[0025]

10 [Fig. 1] Fig. 1 is a cross-sectional view schematically showing a cell culture vessel according to an embodiment of the present invention.

[Fig. 2] Figs. 2(a) and 2(b) are images showing the presence or absence of a sea-island structure.

15 [Fig. 3] Figs. 3(a), 3(b), and 3(c) are diagrams showing a relationship between SF and a planar shape of cells.

MODES FOR CARRYING OUT THE INVENTION

20 [0026]

Hereinafter, the details of the present invention will be described.

[0027]

The cell culture scaffold material according to the
25 present invention contains a peptide-conjugated polyvinyl

alcohol derivative having a polyvinyl alcohol derivative portion and a peptide portion. In the cell culture scaffold material according to the present invention, the cell culture scaffold material has a hydroxyl value of 1,100 mgKOH/g or less, or the peptide-conjugated polyvinyl alcohol derivative has a hydroxyl value of 1,100 mgKOH/g or less.

[0028]

The cell culture scaffold material according to the present invention has the above constitution, and thus has excellent extensibility of pseudopodia and excellent cell proliferation. Further, the cell culture scaffold material according to the present invention has excellent cell adhesion.

[0029]

In the cell culture scaffold material according to the present invention, extension of pseudopodia like filamentous pseudopodia is observed in the cells after seeding, as in the case of using natural polymer materials such as matrigel. This extension of pseudopodia is hardly observed in conventional scaffold materials using synthetic resin materials.

[0030]

In the cell culture scaffold material according to the present invention, cells adhere well to the cell

culture scaffold material and the cells proliferate well even when seeding density of the cells is small.

[0031]

Further, since the cell culture scaffold material
5 according to the present invention can have low hydrophobicity, immersion or swelling of the cell culture scaffold material in the liquid medium can be effectively suppressed. Therefore, cell proliferation can be enhanced.

[0032]

10 Further, the cell culture scaffold material according to the present invention is inexpensive, has less variation between lots and is excellent in safety, in comparison to conventional cell scaffold materials using natural polymer. By using the cell scaffold material according to the
15 present invention, load of cell quality control can be reduced.

[0033]

(Cell culture scaffold material)

The cell culture scaffold material according to the
20 present invention contains a peptide-conjugated polyvinyl alcohol derivative having a polyvinyl alcohol derivative portion and a peptide portion. As the peptide-conjugated polyvinyl alcohol derivative, only one type may be used, or two or more types may be used in combination.

25 [0034]

The peptide-conjugated polyvinyl alcohol derivative has a polyvinyl alcohol derivative portion and a peptide portion. In the peptide-conjugated polyvinyl alcohol derivative, it is preferable that the polyvinyl alcohol derivative portion and the peptide portion are bound via a linker portion. Therefore, the peptide-conjugated polyvinyl alcohol derivative preferably has a polyvinyl alcohol derivative portion, a peptide portion, and a linker portion.

10 [0035]

The peptide-conjugated polyvinyl alcohol derivative can be obtained, for example, by reacting a polyvinyl alcohol derivative with a linker and a peptide, as described later.

15 [0036]

<Polyvinyl alcohol derivative portion>

The polyvinyl alcohol derivative portion is a structural part derived from the polyvinyl alcohol derivative in the peptide-conjugated polyvinyl alcohol derivative. The polyvinyl alcohol derivative is a compound derived from polyvinyl alcohol. The polyvinyl alcohol derivative is preferably a polyvinyl acetal resin, and the polyvinyl alcohol derivative portion is preferably a polyvinyl acetal resin portion. That is, the peptide-conjugated polyvinyl alcohol derivative is preferably a

20

25

peptide-conjugated polyvinyl acetal resin having a polyvinyl acetal resin portion and the peptide portion. As the polyvinyl alcohol derivative and the polyvinyl acetal resin, only one type of each may be used, or two or more
5 types may be used in combination.

[0037]

The polyvinyl alcohol derivative portion and the polyvinyl acetal resin portion preferably have an acetal group, a hydroxyl group, and an acetyl group in side chains.
10 However, the polyvinyl alcohol derivative portion and the polyvinyl acetal resin portion may not have, for example, an acetyl group. For example, by binding of all acetyl groups of the polyvinyl alcohol derivative portion and the polyvinyl acetal resin to the linker, the polyvinyl alcohol
15 derivative portion and the polyvinyl acetal resin portion may not have an acetyl group.

[0038]

The polyvinyl acetal resin can be synthesized by acetalizing polyvinyl alcohol with an aldehyde.
20 [0039]

The aldehyde used for acetalizing polyvinyl alcohol is not particularly limited. Examples of the aldehyde include aldehydes having 1 to 10 carbon atoms. The aldehyde may or may not have a chain aliphatic group, a

cyclic aliphatic group or an aromatic group. The aldehyde may be a chain aldehyde or a cyclic aldehyde.

[0040]

Examples of the aldehyde include formaldehyde, acetaldehyde, propionaldehyde, butyraldehyde, pentanal, hexanal, heptanal, octanal, nonanal, decanal, acrolein, benzaldehyde, cinnamaldehyde, perillaldehyde, formylpyridine, formylimidazole, formylpyrrole, formylpiperidine, formyltriazole, formyltetrazole, formylindole, formylisoindole, formylpurine, formylbenzimidazole, formylbenzotriazole, formylquinoline, formylisoquinoline, formylquinoxaline, formylcinnoline, formylpteridine, formylfuran, formyloxolane, formyloxane, formylthiophene, formylthiolane, formylthiane, formyladenine, formylguanine, formylcytosine, formylthymine, formyluracil, and the like. As the aldehyde, only one type may be used, or two or more types may be used in combination.

[0041]

The aldehyde is preferably formaldehyde, acetaldehyde, propionaldehyde, butyraldehyde, or pentanal, and more preferably butyraldehyde. Therefore, the polyvinyl acetal resin is more preferably a polyvinyl butyral resin, the polyvinyl acetal resin portion is more preferably a polyvinyl butyral resin portion, and the peptide-conjugated

polyvinyl alcohol derivative is more preferably a peptide-conjugated polyvinyl butyral resin.

[0042]

The blending amount of the aldehyde can be
5 appropriately set according to the intended amount of
acetal group. From the viewpoint of increasing efficiency
of an acetalization reaction and easily removing unreacted
aldehyde, the amount of the aldehyde added is preferably 60
mol% or more and more preferably 65 mol% or more, and is
10 preferably 95 mol% or less and more preferably 90 mol% or
less, based on 100 mol% of polyvinyl alcohol.

[0043]

Average degree of polymerization of the polyvinyl
alcohol derivative portion, the polyvinyl acetal resin
15 portion and the polyvinyl acetal resin is preferably 100 or
more, more preferably 200 or more, further preferably 500
or more, and particularly preferably 1500 or more, and is
preferably 6000 or less, more preferably 3000 or less, and
further preferably 2500 or less. When the average degree
20 of polymerization is the above lower limit or more,
swelling due to liquid medium can be effectively suppressed,
so that strength of the cell culture scaffold material can
be maintained satisfactorily. Therefore, cell
proliferation can be enhanced. Further, when the average
25 degree of polymerization is the above upper limit or less,

handleability can be improved, and moldability of the cell culture scaffold material can be improved. The average degree of polymerization of the polyvinyl alcohol derivative portion, the polyvinyl acetal resin portion and the polyvinyl acetal resin is usually the same as average degree of polymerization of the raw material polyvinyl alcohol, thus can be determined by the average degree of polymerization of polyvinyl alcohol.

[0044]

Number average molecular weights (M_n) of the polyvinyl alcohol derivative portion, the polyvinyl acetal resin portion and the polyvinyl acetal resin are preferably 10,000 or more and preferably 600,000 or less. Weight average molecular weights (M_w) of the polyvinyl alcohol derivative portion, the polyvinyl acetal resin portion and the polyvinyl acetal resin are preferably 2,000 or more and preferably 1,200,000 or less. Also, in the polyvinyl alcohol derivative portion, the polyvinyl acetal resin portion and the polyvinyl acetal resin, a ratio (M_w/M_n) of the weight average molecular weight (M_w) to the number average molecular weight (M_n) is preferably 2.0 or more and preferably 40 or less. When the M_n , the M_w and the M_w/M_n are the above lower limit or more and the above upper limit or less, the strength of the cell culture scaffold material can be increased.

[0045]

The number average molecular weights (M_n) and weight average molecular weights (M_w) of the polyvinyl alcohol derivative portion, the polyvinyl acetal resin portion and
5 the polyvinyl acetal resin can be obtained as polystyrene equivalent values, for example, by gel permeation chromatography (GPC) analysis using tetrahydrofuran (THF) as a solvent.

[0046]

10 Degrees of acetalization (degree of butyralization in the case of polyvinyl butyral resin) of the polyvinyl alcohol derivative portion, the polyvinyl acetal resin portion and the polyvinyl acetal resin are preferably 40 mol% or more and more preferably 50 mol% or more, and are
15 90 mol% or less and more preferably 85 mol% or less. When the degree of acetalization is the above lower limit or more, fixation of the cells can be further enhanced, and the cells proliferate efficiently. When the degree of acetalization is the above upper limit or less, solubility
20 in a solvent can be improved.

[0047]

Hydroxyl group contents (amounts of hydroxyl groups) of the polyvinyl alcohol derivative portion, the polyvinyl acetal resin portion and the polyvinyl acetal resin are
25 preferably 15 mol% or more and more preferably 20 mol% or

more, and are preferably 45 mol% or less, more preferably 30 mol% or less, and more preferably 25 mol% or less.

[0048]

Degrees of acetylation (amounts of acetylation groups) of the polyvinyl alcohol derivative portion, the polyvinyl acetal resin portion and the polyvinyl acetal resin are preferably 1 mol% or more and more preferably 2 mol% or more, and are preferably 5 mol% or less and more preferably 4 mol% or less. When the degree of acetylation is the above lower limit or more and the above upper limit or less, a reaction efficiency between the polyvinyl acetal resin and a linker can be enhanced.

[0049]

The degree of acetalization, the degree of acetylation, and the amount of hydroxyl groups of the polyvinyl alcohol derivative portion, the polyvinyl acetal resin portion and the polyvinyl acetal resin can be measured by ^1H -NMR (nuclear magnetic resonance spectrum).

[0050]

20 <Peptide portion>

The peptide portion is a structural part derived from the peptide in the peptide-conjugated polyvinyl alcohol derivative. The peptide portion has an amino acid sequence. The peptide constituting the peptide portion may be an oligopeptide or a polypeptide. As the peptide, only one

type may be used, or two or more types may be used in combination.

[0051]

The peptide portion is preferably composed of 3 or
5 more amino acids, more preferably composed of 4 or more
amino acids and further preferably composed of 5 or more
amino acids, and is preferably composed of 10 or less amino
acids and more preferably composed of 6 or less amino acids.
When the number of amino acids constituting the peptide
10 portion is the above lower limit or more and the above
upper limit or less, cell adhesion and proliferation can be
even more enhanced, and extensibility of pseudopodia can be
even more improved.

[0052]

15 The peptide portion preferably has a cell-adhesive
amino acid sequence. The cell-adhesive amino acid sequence
refers to an amino acid sequence whose cell adhesion
activity has been confirmed by phage display method,
sepharose beads method, or plate coating method. As the
20 phage display method, for example, a method described in
"The Journal of Cell Biology, Volume 130, Number 5,
September 1995 1189-1196" can be used. As the sepharose
beads method, for example, a method described in "Protein,
Nucleic Acid and Enzyme, Vol.45 No.15 (2000) 2477" can be
25 used. As the plate coating method, for example, a method

described in "Protein, Nucleic Acid and Enzyme, Vol.45
No.15 (2000) 2477" can be used.

[0053]

Examples of the cell-adhesive amino acid sequence
5 include RGD sequence (Arg-Gly-Asp), YIGSR sequence (Tyr-
Ile-Gly-Ser-Arg), PDSGR sequence (Pro-Asp-Ser-Gly-Arg), HAV
sequence (His-Ala-Val), ADT sequence (Ala-Asp-Thr), QAV
sequence (Gln-Ala-Val), LDV sequence (Leu-Asp-Val), IDS
sequence (Ile-Asp-Ser), REDV sequence (Arg-Glu-Asp-Val),
10 IDAPS sequence (Ile-Asp-Ala-Pro-Ser), KQAGDV sequence (Lys-
Gln-Ala-Gly-Asp-Val), TDE sequence (Thr-Asp-Glu), and the
like. In addition, examples of the cell-adhesive amino
acid sequence include sequences described in "Medicina
Philosophica, Vol. 9, No. 7, pp. 527-535, 1990" and
15 "Journal of Osaka Women's and Children's Hospital, Vol. 8,
No. 1, pp. 58-66, 1992", and the like. The peptide portion
may have only one type of cell-adhesive amino acid sequence,
or may have two or more types.

[0054]

20 The cell-adhesive amino acid sequence preferably has
at least one of the above-mentioned cell-adhesive amino
acid sequences, more preferably has at least an RGD
sequence, a YIGSR sequence or a PDSGR sequence, and further
preferably has at least an RGD sequence represented by the
25 following formula (1). In this case, cell adhesion and

proliferation can be further enhanced, and the extensibility of pseudopodia can be further improved.

[0055]

Arg-Gly-Asp-X ... Formula (1)

5 [0056]

In Formula (1) above, X represents Gly, Ala, Val, Ser, Thr, Phe, Met, Pro, or Asn.

[0057]

When the peptide portion has the cell-adhesive amino acid sequence, an amino acid at an N-terminal or an amino acid at a C-terminal of the cell-adhesive amino acid sequence and a linker may be bound, and an amino acid constituting an amino acid sequence of a portion different from the cell-adhesive amino acid sequence and a linker may be bound.

15

[0058]

The peptide portion may be linear or may have a cyclic peptide skeleton. The cyclic peptide skeleton is a cyclic skeleton composed of a plurality of amino acids. From the viewpoint of more effectively exhibiting the effect of the present invention, the cyclic peptide skeleton is preferably composed of 4 or more amino acids, more preferably composed of 5 or more amino acids, and preferably composed of 10 or less amino acids.

25 [0059]

When the peptide portion has the cell-adhesive amino acid sequence and has the cyclic peptide skeleton, it is more preferable that the amino acid constituting the amino acid sequence of a portion different from the cell-adhesive amino acid sequence and a linker portion are bound. In this case, cell adhesion and proliferation can be further enhanced, and the extensibility of pseudopodia can be further improved.

[0060]

10 The content of the peptide portion in 100% by weight of the peptide-conjugated polyvinyl alcohol derivative is preferably 0.01% by weight or more, more preferably 0.1% by weight or more, further preferably 1% by weight or more, and particularly preferably 5% by weight or more. The
15 content of the peptide portion in 100% by weight of the peptide-conjugated polyvinyl alcohol derivative is preferably 30% by weight or less, more preferably 25% by weight or less, further preferably 20% by weight or less, and particularly preferably 15% by weight or less. When
20 the content of the peptide portion is the above lower limit or more, cell adhesion and proliferation can be even more enhanced, and the extensibility of pseudopodia can be even more improved.

[0061]

In the peptide-conjugated polyvinyl alcohol derivative, the content of the peptide portion is preferably 0.01 mol% or more, more preferably 0.1 mol% or more, even more preferably 1 mol% or more, further preferably 5 mol% or more, and particularly preferably 10 mol% or more. In the peptide-conjugated polyvinyl alcohol derivative, the content of the peptide portion is preferably 60 mol% or less, more preferably 50 mol% or less, further preferably 35 mol% or less, and particularly preferably 25 mol% or less. When the content of the peptide portion is the above lower limit or more, cell adhesion and proliferation can be even more enhanced, and the extensibility of pseudopodia can be even more improved. When the content of the peptide portion is the above upper limit or less, production cost can be suppressed. The content (mol%) of the peptide portion is amount of substance of the peptide portion with respect to the total of the amount of substance of structural units constituting the peptide-conjugated polyvinyl alcohol derivative.

[0062]

In the peptide-conjugated polyvinyl alcohol derivative, a molar ratio of the content of the peptide portion to a total content of the acetal group, the hydroxyl group and the acetyl group (content of the peptide portion/total content of the acetal group, the hydroxyl

group and the acetyl group) is preferably 0.0001 or more, and more preferably 0.001 or more. When the molar ratio (content of the peptide portion/total content of the acetal group, the hydroxyl group and the acetyl group) is the
5 above lower limit or more, cell adhesion and proliferation can be even more enhanced, and the extensibility of pseudopodia can be even more improved. In the peptide-conjugated polyvinyl alcohol derivative, an upper limit of the molar ratio of the content of the peptide portion to
10 the total content of the acetal group, the hydroxyl group and the acetyl group (content of the peptide portion/total content of the acetal group, the hydroxyl group and the acetyl group) is not particularly limited. From the viewpoint of production cost and the like, the molar ratio
15 (content of the peptide portion/total content of the acetal group, the hydroxyl group and the acetyl group) is preferably 0.2 or less.

[0063]

The content of the peptide portion can be measured by
20 FT-IR or LC-MS.

[0064]

<Linker portion>

The linker portion is a structural part derived from the linker in the peptide-conjugated polyvinyl alcohol
25 derivative. The linker portion is located between the

polyvinyl alcohol derivative portion and the peptide portion. The polyvinyl alcohol derivative portion and the peptide portion are bound via the linker portion. The linker portion is formed by a linker (crosslinking agent).

5 As the linker, only one type may be used, or two or more types may be used in combination.

[0065]

The linker is preferably a compound having a functional group capable of condensing with the carboxyl group or amino group of the peptide. Examples of the functional group capable of condensing with the carboxyl group or amino group of the peptide include a carboxyl group, a thiol group, an amino group, and the like. From the viewpoint of well reacting with a peptide, the linker is preferably a compound having a carboxyl group.

10

15

[0066]

Examples of the linker having a carboxyl group include (meth)acrylic acid, a carboxyl group-containing acrylamide, and the like. By using a carboxylic acid having a polymerizable unsaturated group (carboxylic acid monomer) as the linker having a carboxyl group, the carboxylic acid monomer can be polymerized by graft polymerization at the time of introduction of the linker, so that the number of the carboxyl groups capable of reacting with a peptide can be increased.

20

25

[0067]

From the viewpoint of satisfactorily binding a polyvinyl alcohol derivative and a peptide, the linker is preferably (meth)acrylic acid and more preferably acrylic acid.

[0068]

The peptide-conjugated polyvinyl alcohol derivative can be synthesized, for example, as follows.

[0069]

(1) A polyvinyl alcohol derivative (for example, a polyvinyl acetal resin) is reacted with a linker to obtain a reactant in which the polyvinyl acetal resin and the linker are bound. (2) The obtained reactant is reacted with a peptide to obtain a peptide-conjugated polyvinyl alcohol derivative (peptide-conjugated polyvinyl acetal resin).

[0070]

In (1) above, examples of a method for obtaining a reactant in which the polyvinyl acetal resin and the linker are bound includes a method of acetalizing a copolymer of polyvinyl alcohol and a carboxylic acid having a polymerizable unsaturated group, a method of graft-copolymerizing a polyvinyl acetal resin and a linker (for example, a carboxylic acid monomer) under ultraviolet irradiation, and the like. The method for obtaining a

reactant is preferably the graft copolymerization method. In this case, since the carboxylic acid monomer can be polymerized by graft polymerization, the number of carboxyl groups capable of reacting with a peptide can be increased.

5 [0071]

In (2) above, a peptide-conjugated polyvinyl alcohol derivative (peptide-conjugated polyvinyl acetal resin) having a polyvinyl acetal resin portion, a peptide portion and a linker portion can be obtained by dehydration-
10 condensing a carboxyl group derived from the linker in the obtained reactant and an amino group of the peptide.

[0072]

In the peptide-conjugated polyvinyl alcohol derivative, the carboxyl group derived from the linker may
15 or may not remain. The content of the carboxyl groups of the peptide-conjugated polyvinyl alcohol derivative is preferably 0.1 mol% or more, more preferably 0.5 mol% or more, preferably 2 mol% or less, and more preferably 1.5 mol% or less. When the content of the carboxyl groups is
20 the above lower limit or more and the above upper limit or less, cell adhesion and proliferation can be even more enhanced, and the extensibility of pseudopodia can be even more improved. The content (mol%) of the carboxyl groups is amount of substance of the carboxyl group with respect
25 to the total of the amount of substance of structural units

constituting the peptide-conjugated polyvinyl alcohol derivative.

[0073]

The cell culture scaffold material according to the
5 present invention has constitution (A) or constitution (B)
below.

[0074]

Constitution (A): The cell culture scaffold material
has a hydroxyl value of 1,100 mgKOH/g or less.

10 Constitution (B): The peptide-conjugated polyvinyl
alcohol derivative has a hydroxyl value of 1,100 mgKOH/g or
less.

[0075]

Since the cell culture scaffold material according to
15 the present invention has the constitution (A) or the
constitution (B), hydrophobicity can be enhanced, as
compared to the cell culture scaffold material that does
not have both the constitution (A) and the constitution (B).
Therefore, immersion or swelling of the cell culture
20 scaffold material in the liquid medium can be effectively
suppressed, and cell proliferation can be enhanced. In
particular, high cell proliferation performance can be
maintained even when cells are cultured for a long period
of time.

25 [0076]

The cell culture scaffold material according to the present invention may have only the constitution (A) or may have only the constitution (B) of the constitution (A) and the constitution (B). The cell culture scaffold material
5 according to the present invention may have the constitution (A) and the constitution (B).

[0077]

The cell culture scaffold material has a hydroxyl value of preferably 1,100 mgKOH/g or less, more preferably
10 950 mgKOH/g or less, and further preferably 800 mgKOH/g or less. When the hydroxyl value of the cell culture scaffold material is the above upper limit or less, the hydrophobicity of the cell culture scaffold material can be enhanced, so that immersion or swelling of the cell culture
15 scaffold material in the liquid medium can be even more effectively suppressed. Therefore, cell proliferation can be even more enhanced. The lower limit of the hydroxyl value of the cell culture scaffold material is not particularly limited. The cell culture scaffold material
20 may have a hydroxyl value of, for example, 50 mgKOH/g or more, or 100 mgKOH/g or more.

[0078]

The cell culture scaffold material has an acid value of preferably 1 mgKOH/g or more, more preferably 15 mgKOH/g
25 or more and further preferably 50 mgKOH/g or more, and

preferably 1,400 mgKOH/g or less, more preferably 800 mgKOH/g or less and further preferably 600 mgKOH/g or less. When the acid value of the cell culture scaffold material is the above lower limit or more, the peptide portion is sufficiently introduced, so that the cell adhesion is easily enhanced. When the acid value of the cell culture scaffold material is the above upper limit or less, the cell proliferation is easily enhanced.

[0079]

The peptide-conjugated polyvinyl alcohol derivative has a hydroxyl value of preferably 1,100 mgKOH/g or less, more preferably 950 mgKOH/g or less, and further preferably 800 mgKOH/g or less. When the hydroxyl value of the peptide-conjugated polyvinyl alcohol derivative is the above upper limit or less, the hydrophobicity of the cell culture scaffold material can be enhanced, so that immersion or swelling of the cell culture scaffold material in the liquid medium can be even more effectively suppressed. Therefore, cell proliferation can be even more enhanced. The lower limit of the hydroxyl value of the peptide-conjugated polyvinyl alcohol derivative is not particularly limited. The peptide-conjugated polyvinyl alcohol derivative may have a hydroxyl value of, for example, 50 mgKOH/g or more, or 100 mgKOH/g or more.

[0080]

The peptide-conjugated polyvinyl alcohol derivative has an acid value of preferably 1 mgKOH/g or more, more preferably 15 mgKOH/g or more and further preferably 50 mgKOH/g or more, and preferably 1,400 mgKOH/g or less, more preferably 800 mgKOH/g or less and further preferably 600 mgKOH/g or less. When the acid value of the peptide-conjugated polyvinyl alcohol derivative is the above lower limit or more, the peptide portion is sufficiently introduced, so that the cell adhesion is easily enhanced.

10 When the acid value of the peptide-conjugated polyvinyl alcohol derivative is the above upper limit or less, the cell proliferation is easily enhanced.

[0081]

The hydroxyl value and acid value of the cell culture scaffold material and the peptide-conjugated polyvinyl alcohol derivative can be measured with reference to neutralization titration method of JIS K0070. Specifically, the values can be measured as follows.

[0082]

20 <Measurement of acid value>

The following instrument and reagents are prepared.

Instrument: burette

Solvent: a mixed liquid of 50 ml of ethanol and 50 ml of diethyl ether

Titrant: a 0.1 mol/L potassium hydroxide-ethanol solution

Sample: a cell culture scaffold material or a peptide-conjugated polyvinyl alcohol derivative

5 [0083]

The acid value is measured according to the following procedure.

(1) Add 5 g of the sample and 100 mL of the solvent to a 300 mL Erlenmeyer flask, and dissolve the sample in
10 the solvent. After dissolution, add a few drops of a phenolphthalein solution prepared according to JIS K8001.

(2) Fill a 25 ml burette with the titrant for titration, and define a time when light red coloration of the phenolphthalein solution continues for 30 seconds as an
15 end point.

(3) Perform a blank test in the same way.

(4) Calculate acid value by Formula (X) below.

[0084]

Acid value (mgKOH/g) = $V \times f \times 5.611/S$... (X)

20 S: Sample mass (g)

V: Titration volume (mL) in this test

f: Titrant factor

[0085]

<Measurement of hydroxyl value>

25 The following instrument and reagents are prepared.

Instrument: burette

Acetylation reagent: a solution obtained by adding pyridine to 25 g of acetic anhydride to make a total volume of 100 mL

5 Titrant: a 0.5 mol/L potassium hydroxide-ethanol solution

Sample: a cell culture scaffold material or a peptide-conjugated polyvinyl alcohol derivative
[0086]

10 The hydroxyl value is measured according to the following procedure.

(1) Add the sample and 5 mL of acetylation reagent to a 100 mL Erlenmeyer flask and react them in an oil bath at 105°C for 1 hour.

15 (2) After cooling, add 1 mL of water and react them in the oil bath at 105°C for 10 minutes.

(3) After cooling, rinse a wall surface with 5 mL of ethanol to dilute. After dilution, add a few drops of a phenolphthalein solution.

20 (4) Fill a 25 ml burette with the titrant for titration, and define a time when light red coloration of the phenolphthalein solution continues for 30 seconds as an end point.

(5) Perform a blank test in the same way.

25 (6) Calculate hydroxyl value by Formula (Y) below.

[0087]

Hydroxyl value (mgKOH/g) = $[(V_0 - V_1) \times f \times 28.05/S] +$

A ... (Y)

S: Sample mass (g)

5 V_0 : Titration volume (mL) in blank test

V_1 : Titration volume (mL) in this test

f: Titrant factor

A: Acid value

[0088]

10 From the viewpoint of further enhancing cell adhesion and proliferation, the cell culture scaffold material preferably has a phase-separated structure. The phase-separated structure has at least a first phase and a second phase.

15 [0089]

Examples of the phase-separated structure include microphase-separated structures such as a sea-island structure, a cylinder structure, a gyroid structure, and a lamellar structure. In the sea-island structure, for
20 example, the first phase can be a sea part and the second phase can be an island part. In the cylinder structure, gyroid structure, or lamellar structure, for example, a phase having a largest surface area can be the first phase, and a phase having a second largest surface area can be the
25 second phase. The cell culture scaffold material has a

continuous phase and a discontinuous phase, thereby enhancing affinity with cells, and cell adhesion and proliferation can be further enhanced.

[0090]

5 The phase-separated structure is preferably a sea-island structure. The cell culture scaffold material preferably has a sea-island structure. In this case, cell adhesion and proliferation can be further enhanced.

[0091]

10 When the cell culture scaffold material has a sea-island structure, surface area fraction of the island part (second phase) with respect to the entire surface of the cell culture scaffold material is preferably 0.01 or more, more preferably 0.1 or more, further preferably 0.2 or more,
15 preferably 0.95 or less, more preferably 0.9 or less, and further preferably 0.8 or less. When the surface area fraction is the above lower limit or more and the above upper limit or less, cell adhesion can be further enhanced.

[0092]

20 When the cell culture scaffold material has a sea-island structure, it is preferable that the island part contains a peptide portion. That is, it is preferable that the cell culture scaffold material has a sea part and an island part, and the island part contains a peptide portion.
25 In this case, adhesion domains of the cells are accumulated

in the island part, whereby cell adhesion can be further enhanced.

[0093]

The presence or absence of a phase-separated
5 structure can be confirmed by, for example, an atomic force
microscope (AFM), a transmission electron microscope (TEM),
a scanning electron microscope (SEM), or the like. Further,
the surface area fraction can be obtained from a microscope
observation image using image analysis software such as
10 ImageJ.

[0094]

The phase-separated structure can be formed, for
example, by increasing the content of peptide portion and
forming a phase-separated structure between or within
15 molecules of a peptide-conjugated polyvinyl alcohol
derivative.

[0095]

From the viewpoint of effectively exerting the effect
of the present invention and enhancing productivity, the
20 content of the peptide-conjugated polyvinyl alcohol
derivative in 100% by weight of the cell culture scaffold
material is preferably 90% by weight or more, more
preferably 95% by weight or more, further preferably 97.5%
by weight or more, particularly preferably 99% by weight or
25 more, and most preferably 100% by weight (whole amount).

Therefore, it is most preferable that the cell culture scaffold material is the peptide-conjugated polyvinyl alcohol derivative. When the content of the peptide-conjugated polyvinyl alcohol derivative is the above lower
5 limit or more, the effect of the present invention can be even more effectively exhibited.

[0096]

The cell culture scaffold material may contain a polymer other than the peptide-conjugated polyvinyl alcohol
10 derivative. Examples of the polymer include polyvinyl acetal resins, polyolefin resins, polyether resins, polyvinyl alcohol resins, polyesters, epoxy resins, polyamide resins, polyimide resins, polyurethane resins, polycarbonate resins, celluloses, polypeptides, and the
15 like. As the polymer, only one type may be used, or two or more types may be used in combination.

[0097]

From the viewpoint of effectively exerting the effect of the present invention, the smaller content of the
20 polymer other than the peptide-conjugated polyvinyl alcohol derivative, the better. The content of the polymer in 100% by weight of the cell culture scaffold material is preferably 10% by weight or less, more preferably 5% by weight or less, further preferably 2.5% by weight or less,
25 particularly preferably 1% by weight or less, and most

preferably 0% by weight (not contained). Therefore, it is most preferable that the cell culture scaffold material does not contain a polymer other than the peptide-conjugated polyvinyl alcohol derivative.

5 [0098]

It is preferable that the cell culture scaffold material according to the present invention does not substantially contain animal-derived raw materials. By substantially not containing animal-derived raw materials,
10 it is possible to provide a cell culture scaffold material that has less variation between lots and is excellent in cost and safety. In addition, the phrase "does not substantially contain animal-derived raw materials" means that the animal-derived raw materials in the cell culture
15 scaffold material are 3% by weight or less. In the cell culture scaffold material according to the present invention, the animal-derived raw materials in the cell culture scaffold material are preferably 1% by weight or less, and more preferably 0% by weight. That is, it is
20 more preferable that the cell culture scaffold material does not contain animal-derived raw materials in the cell culture scaffold material.

[0099]

The cell culture scaffold material may be prepared on
25 a surface of a vessel body described later. For example,

the peptide-conjugated polyvinyl alcohol derivative may be obtained by coating a synthetic resin having a polyvinyl alcohol derivative portion and a linker on the surface of the vessel body to form a resin film, and reacting the synthetic resin and a peptide on a surface of the resin film.

[0100]

(Other details of cell culture scaffold material)

The cell culture scaffold material according to the present invention is used for culturing cells. The cell culture scaffold material according to the present invention is used as a scaffold for cells when culturing the cells.

[0101]

Examples of the cells include cells of animals such as human, mouse, rat, pig, cow and monkey. In addition, examples of the cells include somatic cells and the like, and examples thereof include stem cells, progenitor cells, mature cells, and the like. The somatic cells may be cancer cells.

[0102]

Examples of the mature cells include nerve cells, cardiomyocytes, retinal cells, hepatocytes, and the like.

[0103]

Examples of the stem cells include mesenchymal stem cells (MSCs), iPS cells, ES cells, Muse cells, embryonic cancer cells, embryonic germ cells, mGS cells, and the like.
[0104]

5 Shape of the cell culture scaffold material is not particularly limited. The cell culture scaffold material may be in a film form, a particle form, a fibrous form, or a porous body form. The film form includes a film form and a sheet form.

10 [0105]

 The cell culture scaffold material is preferably used for two-dimensional culture (plane culture), three-dimensional culture or suspension culture of cells, and more preferably used for two-dimensional culture (plane
15 culture).

[0106]

 In addition, the cell culture scaffold material can also be used as a cell culture carrier (medium) containing the cell culture scaffold material and polysaccharides.
20 The polysaccharide is not particularly limited, and a conventionally known polysaccharide can be used. The polysaccharide is preferably a water-soluble polysaccharide.

[0107]

 Further, the cell culture scaffold material can also
25 be used as a fiber for cell culture having a fiber body and

a cell culture scaffold material arranged on the surface of the fiber body. In this case, the cell culture scaffold material is preferably coated on the surface of the fiber body, and is preferably a coated material. In this fiber
5 for cell culture, a cell culture scaffold material may be present in the fiber body. For example, the cell culture scaffold material can be present in the fiber body by impregnating or kneading the fiber body into the liquid cell culture scaffold material. In general, stem cells
10 have a property of being difficult to adhere to a planar structure and easily adhering to a three-dimensional structure such as a fibrous structure. Therefore, a fiber for cell culture is suitably used for three-dimensional culture of stem cells. Among stem cells, it is more
15 preferably used for three-dimensional culture of adipose stem cells.

[0108]

The synthetic resin in the cell culture scaffold material may be crosslinked. The cell culture scaffold
20 material containing a crosslinked synthetic resin is effectively suppressed in water swelling properties and can increase strength. By using a crosslinking agent, the synthetic resin can be crosslinked.

[0109]

Examples of the crosslinking agent include polyalcohol, polycarboxylic acid, hydroxycarboxylic acid, metal soap, polysaccharide, and the like.

[0110]

5 (Cell culture vessel)

The cell culture vessel according to the present invention includes a vessel body and the above-mentioned cell culture scaffold material, and the cell culture scaffold material is arranged on a surface of the vessel
10 body. The cell culture vessel includes the cell culture scaffold material in at least a part of cell culture area.

[0111]

Fig. 1 is a cross-sectional view schematically showing a cell culture vessel according to an embodiment of
15 the present invention.

[0112]

A cell culture vessel 1 includes a vessel body 2 and a cell culture scaffold material 3. The cell culture scaffold material 3 is arranged on a surface 2a of the
20 vessel body 2. The cell culture scaffold material 3 is arranged on a bottom surface of the vessel body 2. Cells can be cultured in plane by adding a liquid medium to the cell culture vessel 1 and seeding cells such as cell mass on a surface of the cell culture scaffold material 3.

25 [0113]

The vessel body may include a first vessel body, and a second vessel body such as a cover glass on the bottom surface of the first vessel body. The first vessel body and the second vessel body may be separable. In this case, 5 the cell culture scaffold material may be arranged on the surface of the second vessel body.

[0114]

As the vessel body, a conventionally known vessel body (vessel) can be used. Shape and size of the vessel 10 body are not particularly limited.

[0115]

Examples of the vessel body include a cell culture plate provided with one or a plurality of wells (holes), a cell culture flask, and the like. The number of wells in 15 the plate is not particularly limited. The number of wells is not particularly limited, and examples thereof include 2, 4, 6, 12, 24, 48, 96, 384, and the like. Shape of the well is not particularly limited, and examples thereof include a perfect circle, an ellipse, a triangle, a square, a 20 rectangle, a pentagon, and the like. Shape of the bottom surface of the well is not particularly limited, and examples thereof include a flat bottom, a round bottom, unevenness, and the like.

[0116]

Material of the vessel body is not particularly limited, and examples thereof include resins, metals, and inorganic materials. Examples of the resin include polystyrene, polyethylene, polypropylene, polycarbonate, polyester, polyisoprene, cycloolefin polymer, polyimide, polyamide, polyamideimide, (meth)acrylic resin, epoxy resin, silicone, and the like. Examples of the metal include stainless steel, copper, iron, nickel, aluminum, titanium, gold, silver, platinum, and the like. Examples of the inorganic material include silicon oxide (glass), aluminum oxide, titanium oxide, zirconium oxide, iron oxide, silicon nitride, and the like.

[0117]

The present invention will be described in more detail below with reference to Examples and Comparative Examples. The present invention is not limited to these examples.

[0118]

The content of structural units in the obtained synthetic resin was measured by ^1H -NMR (nuclear magnetic resonance spectrum) after dissolving a synthetic resin in DMSO-d₆ (dimethylsulfoxide). Also, the content of peptide in the peptide-conjugated polyvinyl alcohol derivative was measured by FT-IR or LC-MS. Tables 1 and 2 show degrees of acetalization (degrees of butyralization), amounts of

hydroxyl groups, degrees of acetylation, contents of carboxyl groups, and contents of the peptide portion of the obtained synthetic resins.

[0119]

5 (Example 1)

Preparation of polyvinyl acetal resin (PVB1):

A reactor equipped with a stirrer was charged with 2700 mL of ion-exchanged water, 300 parts by weight of polyvinyl alcohol with an average degree of polymerization
10 of 1700 and a degree of saponification of 99 mol%, followed by dissolution by heating with stirring to obtain a solution. To the obtained solution, 35% by weight hydrochloric acid as a catalyst was added such that the concentration of hydrochloric acid became 0.2% by weight.
15 Subsequently, temperature was adjusted to 15°C, and 22 parts by weight of n-butyraldehyde was added thereto with stirring. Then, 148 parts by weight of n-butyraldehyde was added thereto to precipitate a white particulate polyvinyl acetal resin (polyvinyl butyral resin). Fifteen minutes
20 after the precipitation, 35% by weight hydrochloric acid was added such that the concentration of hydrochloric acid became 1.8% by weight, and then the mixture was heated to 50°C and kept at 50°C for 2 hours. Next, the solution was cooled and neutralized, and then the polyvinyl butyral
25 resin was washed with water and dried to obtain a polyvinyl

acetal resin (polyvinyl butyral resin (PVB1), an average degree of polymerization of 1700, a degree of acetalization (degree of butyralization) of 70 mol%, an amount of hydroxyl groups of 27 mol%, and a degree of acetylation of 3 mol%).

[0120]

Introduction of linker:

Ninety nine parts by weight of the obtained polyvinyl acetal resin and 1 part by weight of acrylic acid (linker) were dissolved in 300 parts by weight of THF and reacted in the presence of a photoradical polymerization initiator for 20 minutes under ultraviolet irradiation to graft-copolymerize a polyvinyl acetal resin with acrylic acid, thereby introducing the linker. One part by weight of the polyvinyl acetal resin into which the linker was introduced was dissolved in 19 parts by weight of butanol. The obtained solution (150 μ L) was discharged onto a surface of a ϕ 22 mm cover glass ("22 round No. 1" manufactured by Matsunami Glass Ind., Ltd.) subjected to dust removal with an air duster, rotated at 2000 rpm for 20 seconds using a spin coater, and then heated at 60°C for 60 minutes to obtain a resin film with a smooth surface.

[0121]

Formation of peptide portion:

A linear peptide having an amino acid sequence of Arg-Gly-Asp-Ser (four amino acid residues, described as RGDS in the table) was prepared. One part by weight of this peptide and 1 part by weight of 1-ethyl-3-(3-
5 dimethylaminopropyl)carbodiimide hydrochloride (condensing agent) were added to phosphate buffered saline containing neither calcium nor magnesium so that the final concentration of the peptide is 1 mM to prepare a peptide-containing solution. One part by weight of this peptide-
10 containing liquid was added to a spin-coated resin film (polyvinyl acetal resin into which a linker was introduced) and reacted to dehydrate and condense a carboxyl group of the linker and an amino group of Arg of the peptide. In this way, a peptide-conjugated polyvinyl acetal resin
15 having a polyvinyl acetal resin portion, a linker portion and a peptide portion was prepared.

[0122]

The obtained peptide-conjugated polyvinyl acetal resin had a degree of acetalization (degree of
20 butyralization) of 69.3 mol%, an amount of hydroxyl groups of 26.7 mol%, a degree of acetylation of 3.0 mol%, a content of carboxyl groups of 0.9 mol%, and a content of peptide portion of 0.1 mol%.

[0123]

25 Preparation of cell culture vessel:

A laminate of the obtained peptide-conjugated polyvinyl acetal resin and the cover glass was arranged on a $\phi 22$ mm polystyrene dish to obtain a cell culture vessel.
[0124]

5 (Example 2)

A resin film (polyvinyl acetal resin into which a linker was introduced) was obtained in the same manner as in Example 1.
[0125]

10 Formation of peptide portion:

A cyclic peptide having an amino acid sequence of Arg-Gly-Asp-Phe-Lys (five amino acid residues, a cyclic peptide skeleton formed by binding Arg and Lys, D-form Phe, described as c-RGDfK in the table) was prepared. One part
15 by weight of this peptide and 1 part by weight of 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide hydrochloride (condensing agent) were added to phosphate buffered saline containing neither calcium nor magnesium so that the final concentration of the peptide is 1 mM to prepare a peptide-
20 containing solution. One part by weight of this peptide-containing liquid was added to a spin-coated resin film (polyvinyl acetal resin into which a linker was introduced) and reacted to dehydrate and condense a carboxyl group of the linker and an amino group of Lys of the peptide. In
25 this way, a peptide-conjugated polyvinyl acetal resin

having a polyvinyl acetal resin portion, a linker portion and a peptide portion was prepared.

[0126]

Preparation of cell culture vessel:

5 A cell culture vessel was obtained in the same manner as in Example 1.

[0127]

(Example 3)

 A resin film (polyvinyl acetal resin into which a
10 linker was introduced) was obtained in the same manner as in Example 1.

[0128]

Formation of peptide portion:

 A linear peptide having an amino acid sequence of
15 Gly-Arg-Gly-Asp-Ser (five amino acid residues, described as GRGDS in the table) was prepared. A peptide-conjugated polyvinyl acetal resin was prepared in the same manner as in Example 1 except that the amount of the peptide added was 10 parts by weight.

20 [0129]

Preparation of cell culture vessel:

 A cell culture vessel was obtained in the same manner as in Example 1.

[0130]

25 (Example 4)

A peptide-conjugated polyvinyl acetal resin and a cell culture vessel were prepared in the same manner as in Example 3 except that 70 parts by weight of PVB1 and 30 parts by weight of acrylic acid (linker) were used in the introduction of the linker, and the amount of the peptide added was changed to 30 parts by weight in the formation of the peptide portion.

[0131]

(Example 5)

10 A peptide-conjugated polyvinyl acetal resin and a cell culture vessel were prepared in the same manner as in Example 3 except that 50 parts by weight of PVB1 and 50 parts by weight of acrylic acid (linker) were used in the introduction of the linker, and the amount of the peptide added was changed to 40 parts by weight in the formation of the peptide portion.

[0132]

(Example 6)

20 A peptide-conjugated polyvinyl acetal resin and a cell culture vessel were prepared in the same manner as in Example 3 except that 30 parts by weight of PVB1 and 70 parts by weight of acrylic acid (linker) were used in the introduction of the linker, and the amount of the peptide added was changed to 70 parts by weight in the formation of the peptide portion.

[0133]

(Example 7)

Preparation of polyvinyl acetal resin (PVB2):

A reactor equipped with a stirrer was charged with
5 2700 mL of ion-exchanged water, 300 parts by weight of
polyvinyl alcohol with an average degree of polymerization
of 1700 and a degree of saponification of 99 mol%, followed
by dissolution by heating with stirring to obtain a
solution. To the obtained solution, 35% by weight
10 hydrochloric acid as a catalyst was added such that the
concentration of hydrochloric acid became 0.2% by weight.
Subsequently, temperature was adjusted to 15°C, and 22
parts by weight of n-butyraldehyde was added thereto with
stirring. Then, 143 parts by weight of n-butyraldehyde was
15 added to precipitate a white particulate polyvinyl acetal
resin (polyvinyl butyral resin). Fifteen minutes after the
precipitation, 35% by weight hydrochloric acid was added
such that the concentration of hydrochloric acid became
1.8% by weight, and then the mixture was heated to 50°C and
20 kept at 50°C for 2 hours. Next, the solution was cooled
and neutralized, and then the polyvinyl butyral resin was
washed with water and dried to obtain a polyvinyl acetal
resin (polyvinyl butyral resin (PVB2), an average degree of
polymerization of 1700, a degree of acetalization (degree

of butyralization) of 69 mol%, an amount of hydroxyl groups of 28 mol%, and a degree of acetylation of 3 mol%).

[0134]

Introduction of linker:

5 Seventy parts by weight of the obtained polyvinyl acetal resin and 30 parts by weight of acrylic acid (linker) were dissolved in 300 parts by weight of THF and reacted in the presence of a photoradical polymerization initiator for 20 minutes under ultraviolet irradiation to
10 graft-copolymerize a polyvinyl acetal resin with acrylic acid, thereby introducing the linker. One part by weight of the polyvinyl acetal resin into which the linker was introduced was dissolved in 19 parts by weight of butanol. The obtained solution (150 μ L) was discharged onto a
15 surface of a ϕ 22 mm cover glass ("22 round No. 1" manufactured by Matsunami Glass Ind., Ltd.) subjected to dust removal with an air duster, rotated at 2000 rpm for 20 seconds using a spin coater, and then heated at 60°C for 60 minutes to obtain a resin film with a smooth surface.

20 [0135]

Formation of peptide portion:

 A peptide-conjugated polyvinyl acetal resin was prepared in the same manner as in Example 4 except that the obtained resin film (polyvinyl acetal resin into which a
25 linker was introduced) was used.

[0136]

Preparation of cell culture vessel:

A cell culture vessel was obtained in the same manner as in Example 1.

5 [0137]

(Example 8)

Preparation of polyvinyl acetal resin (PVB3):

A reactor equipped with a stirrer was charged with 2700 mL of ion-exchanged water, 300 parts by weight of polyvinyl alcohol with an average degree of polymerization of 1700 and a degree of saponification of 99 mol%, followed by dissolution by heating with stirring to obtain a solution. To the obtained solution, 35% by weight hydrochloric acid as a catalyst was added such that the concentration of hydrochloric acid became 0.2% by weight. Subsequently, temperature was adjusted to 15°C, and 22 parts by weight of n-butyraldehyde was added thereto with stirring. Then, 138 parts by weight of n-butyraldehyde was added to precipitate a white particulate polyvinyl acetal resin (polyvinyl butyral resin). Fifteen minutes after the precipitation, 35% by weight hydrochloric acid was added such that the concentration of hydrochloric acid became 1.8% by weight, and then the mixture was heated to 50°C and kept at 50°C for 2 hours. Next, the solution was cooled and neutralized, and then the polyvinyl butyral resin was

washed with water and dried to obtain a polyvinyl acetal resin (polyvinyl butyral resin (PVB3), an average degree of polymerization of 1700, a degree of acetalization (degree of butyralization) of 67 mol%, an amount of hydroxyl groups of 30 mol%, and a degree of acetylation of 3 mol%).

[0138]

Introduction of linker:

A linker was introduced in the same manner as in Example 7 except that the obtained polyvinyl acetal resin was used.

[0139]

Formation of peptide portion:

A peptide-conjugated polyvinyl acetal resin was prepared in the same manner as in Example 4 except that the obtained resin film (polyvinyl acetal resin into which a linker was introduced) was used.

[0140]

Preparation of cell culture vessel:

A cell culture vessel was obtained in the same manner as in Example 1.

[0141]

(Example 9)

Preparation of polyvinyl acetal resin (PVB4):

A reactor equipped with a stirrer was charged with 2700 mL of ion-exchanged water, 300 parts by weight of

polyvinyl alcohol with an average degree of polymerization of 1700 and a degree of saponification of 99 mol%, followed by dissolution by heating with stirring to obtain a solution. To the obtained solution, 35% by weight hydrochloric acid as a catalyst was added such that the concentration of hydrochloric acid became 0.2% by weight. Subsequently, temperature was adjusted to 15°C, and 22 parts by weight of n-butyraldehyde was added thereto with stirring. Then, 100 parts by weight of n-butyraldehyde was added to precipitate a white particulate polyvinyl acetal resin (polyvinyl butyral resin). Fifteen minutes after the precipitation, 35% by weight hydrochloric acid was added such that the concentration of hydrochloric acid became 1.8% by weight, and then the mixture was heated to 50°C and kept at 50°C for 2 hours. Next, the solution was cooled and neutralized, and then the polyvinyl butyral resin was washed with water and dried to obtain a polyvinyl acetal resin (polyvinyl butyral resin (PVB4), an average degree of polymerization of 1700, a degree of acetalization (degree of butyralization) of 50 mol%, an amount of hydroxyl groups of 47 mol%, and a degree of acetylation of 3 mol%).

[0142]

Introduction of linker:

A linker was introduced in the same manner as in Example 7 except that the obtained polyvinyl acetal resin was used.

[0143]

5 Formation of peptide portion:

A peptide-conjugated polyvinyl acetal resin was prepared in the same manner as in Example 4 except that the obtained resin film (polyvinyl acetal resin into which a linker was introduced) was used.

10 [0144]

Preparation of cell culture vessel:

A cell culture vessel was obtained in the same manner as in Example 1.

[0145]

15 (Example 10)

A resin film (polyvinyl acetal resin into which a linker was introduced) was obtained in the same manner as in Example 4.

[0146]

20 Formation of peptide portion:

A linear peptide having an amino acid sequence of Gly-Arg-Gly-Asp-Ser-Pro (six amino acid residues, described as GRGDSP in the table) was prepared. A peptide-conjugated polyvinyl acetal resin having a polyvinyl acetal resin
25 portion, a linker portion and a peptide portion was

prepared, in the same manner as in Example 4 except that this peptide was used.

[0147]

Preparation of cell culture vessel:

5 A cell culture vessel was obtained in the same manner as in Example 1.

[0148]

(Comparative Example 1)

 Ninety nine parts by weight of a polyvinyl alcohol
10 with an average degree of polymerization of 1700 and a degree of saponification of 90 mol%, and 1 part by weight of acrylic acid (linker) were dissolved in 300 parts by weight of ethanol and reacted in the presence of a photoradical polymerization initiator for 20 minutes under
15 ultraviolet irradiation to graft-copolymerize a polyvinyl alcohol with acrylic acid, thereby introducing the linker. A peptide-conjugated polyvinyl alcohol derivative and a cell culture vessel were prepared in the same manner as in Example 1 except that a linear peptide having an amino acid
20 sequence of Gly-Arg-Gly-Asp-Ser (five amino acid residues, described as GRGDS in the table) was used, and the carboxyl group of the linker and the amino group of Gly of the peptide were dehydrated and condensed.

[0149]

25 (Comparative Example 2)

A resin film (polyvinyl acetal resin into which a linker was introduced) was obtained in the same manner as in Example 1. In Comparative Example 2, the peptide portion was not formed. Moreover, the cell culture vessel
5 was obtained in the same manner as in Example 1.

[0150]

(Reference Example A)

Preparation of scaffolding derived from natural product:

A Vitronectin (manufactured by Corning Incorporated)
10 solution (1 ml) adjusted to 5 µg/ml in phosphate buffer (PBS) was added to a φ35 mm dish. A φ22 mm cover glass ("22 round No. 1" manufactured by Matsunami Glass Ind., Ltd.) was immersed therein and cured at 37°C for 1 hour, whereby scaffolding derived from a natural product in which
15 Vitronectin (described as VTN in the table) was smoothly adsorbed on a surface was obtained.

[0151]

Preparation of cell culture vessel:

A cell culture vessel was obtained in the same manner
20 as in Example 1. Since Vitronectin is denatured when dried and its adhesive performance is significantly reduced, the cell culture vessel was immersed in a PBS solution immediately after being prepared.

[0152]

25 (Evaluation)

(1) Measurement of hydroxyl value and acid value

The hydroxyl value and acid value of the cell culture scaffold material were measured by the above-mentioned method by the neutralization titration method described in
5 JIS K0070.

[0153]

(2) Presence or absence of sea-island structure

The resin films of the obtained peptide-conjugated polyvinyl acetal resins (Examples 1 to 10 and Comparative
10 Example 1) and the resin film of the polyvinyl acetal resin into which a linker was introduced (Comparative Example 2) were immersed in a PBS solution for 30 minutes. The immersed resin film was observed with an atomic force microscope (AFM, "Dimension XR" manufactured by Bruker).
15 Under measurement conditions where peak set point was set to 2 nN in QNM mode, the range of $1\text{ }\mu\text{m} \times 1\text{ }\mu\text{m}$ was observed. The presence or absence of the sea-island structure was determined by comparing the obtained height mapping image and elastic modulus mapping image. In the table, when the
20 sea-island structure was observed, it was described as "A", and when the sea-island structure was not observed, it was described as "B".

[0154]

Fig. 2(a) is an example of an image in which the sea-
25 island structure is determined to be observed, and Fig.

2(b) is an example of an image in which the sea-island structure is determined not to be observed. Specifically, Fig. 2(a) is an image of the cell culture scaffold material obtained in Example 7, and Fig. 2(b) is an image of the
5 cell culture scaffold material obtained in Example 1.

[0155]

(3) Cell culture evaluation

(3-1) Seeding and culture of iPS cells

The following liquid medium and ROCK (Rho-associated
10 kinase)-specific inhibitor were prepared.

[0156]

TeSR E8 medium (manufactured by STEMCELL Technologies Inc.)

ROCK-Inhibitor (Y27632)

15 [0157]

Phosphate buffered saline (1 mL) was added to the obtained cell culture vessel, and the mixture was allowed to stand in an incubator at 37°C for 1 hour, then the phosphate buffered saline was removed from the cell culture
20 vessel.

[0158]

To h-iPS cells 253G1 in a confluent state in a ϕ 35 mm dish, 1 mL of a 0.5 mM ethylenediaminetetraacetic acid/phosphate buffer solution was added, and the mixture
25 was allowed to stand at room temperature for 2 minutes.

The ethylenediaminetetraacetic acid/phosphate buffer solution was removed, followed by pipetting with 1 mL of liquid medium to obtain a cell mass crushed to a size of 50 μm to 200 μm . The obtained cell mass (cell number 1.0×10^5 cells) was clamp-seeded on the cell culture vessel.

[0159]

A liquid medium (1 mL), and a ROCK-specific inhibitor in an amount so as to have a final concentration of 10 μM were added to the cell culture vessel, and the cells were cultured in an incubator at 37°C and a CO₂ concentration of 5%. The liquid medium (1 mL) was removed every 24 hours, and 1 mL of fresh liquid medium was added to replace the medium.

[0160]

15 (3-2) Seeding and culture of MSC

The following liquid medium and additives were prepared. MesenCult-ACF Plus 500X Supplement and L-Glutamine 200 mmol/L (100X) were added to MesenCult-ACF Plus Medium (liquid medium), so that the final concentration was 1X.

[0161]

MesenCult-ACF Plus Medium (manufactured by STEMCELL Technologies Inc.)

MesenCult-ACF Plus 500X Supplement (manufactured by STEMCELL Technologies Inc.)

L-Glutamine 200 mmol/L (100X) (manufactured by FUJIFILM Wako Pure Chemical Corporation)

[0162]

The following mesenchymal stem cells (MSCs) were prepared. Marrow stromal cells containing MSCs were acclimated in MSC medium, and cells having a purity of 95% or more for MSC positive markers (CD73, CD90, CD105) and less than 5% for MSC negative markers (CD14, CD34, CD45) were used as MSCs.

10 [0163]

Human Bone Marrow Stromal Cells Derived in ACF Medium (manufactured by STEMCELL Technologies Inc.)

[0164]

Phosphate buffered saline (1 mL) was added to the obtained cell culture vessel, and the mixture was allowed to stand in an incubator at 37°C for 1 hour, then the phosphate buffered saline was removed from the cell culture vessel.

[0165]

20 MSCs in a confluent state were placed in a ϕ 35 mm dish, 2 mL of ACF Enzymatic Dissociation Solution (manufactured by STEMCELL Technologies Inc.) was added thereto, and the mixture was allowed to stand in an incubator at 37°C and a CO₂ concentration of 5% for 3
25 minutes. Further, 2 mL of ACF Enzyme Inhibition Solution

(manufactured by STEMCELL Technologies Inc.) was added thereto. After centrifugation at 300 rpm for 8 minutes, a supernatant was removed and suspended in a liquid medium to obtain a cell suspension. The obtained cell suspension
5 (number of cells 8.0×10^4 cells) was seeded in the cell culture vessel.

[0166]

At the time of seeding, 1.5 mL of liquid medium was added to the cell culture vessel. In addition, the cells
10 were cultured in an incubator at 37°C and a CO₂ concentration of 5%.

[0167]

(3-3) Extensibility of pseudopodia

Cells 24 hours after cell seeding were observed using
15 a phase-contrast microscope (Olympus "IX73", 10 × 20 times). In the observation, images of a visual field showing the most average adhesive form in the cell culture vessel were obtained. Extensibility of pseudopodia was evaluated by determining a shape factor (SF) from the obtained images.
20 The shape factor (SF) is a shape evaluation coefficient of a region in a plan view of a cell after culturing the cell, and is determined by the following formula.

[0168]

Formula: $SF = 4 \times \pi \times (\text{Plane area of cell}) / (\text{Length of}$
25 $\text{outer periphery of cell})^2$

[0169]

Figs. 3(a), 3(b), and 3(c) are diagrams showing a relationship between SF and a planar shape of cells. As shown in Fig. 3(a), when the SF is 1, the planar shape of the cell is circular. The smaller the SF, the farther away from the circle, which means that the pseudopodia of the cell are well extended. Fig. 3(b) is a photograph showing the planar shape of the cell when $SF \approx 0.3$, and Fig. 3(c) is a photograph showing the planar shape of the cell when $SF \approx 1$.

10 [0170]

<Criteria for extensibility of pseudopodia>

o: SF is 0.1 or more and 0.6 or less

x: SF exceeds 0.6 and 1 or less

[0171]

15 (3-4) Cell proliferation (1)

Cells 5 days after cell seeding were observed with a phase-contrast microscope. Whether or not the cell mass was larger than that at the time of seeding was visually confirmed.

20 [0172]

<Criteria for cell proliferation (1)>

o: The cell mass is larger than that at the time of seeding, and cell proliferation can be confirmed

×: The cell mass does not change as compared to the time of seeding, or the cell mass is exfoliated and no cell mass is present

[0173]

5 (3-5) Cell proliferation (2)

The number of cells 5 days after cell seeding was determined using a cell counter ("NucleoCounter Nc-3000" manufactured by Chemometec). Next, a cell proliferation rate relative to Reference Example A was determined using
10 the following formula.

[0174]

Cell proliferation rate relative to Reference Example A (%) = (Number of cells in Examples or Comparative Examples)/(Number of cells in Reference Example A) × 100

15 [0175]

<Criteria for cell proliferation (2)>

AA: Cell proliferation rate of 100% or more relative to Reference Example A

A: Cell proliferation rate relative to Reference
20 Example A is 50% or more and less than 100%

B: Cell proliferation rate relative to Reference Example A is 10% or more and less than 50%

C: Cell proliferation rate relative to Reference Example A is less than 10%

25 [0176]

Details and results are shown in Tables 1 and 2 below.

[0177]

EXPLANATION OF SYMBOLS

[0179]

- 1: Cell culture vessel
- 5 2: Vessel body
- 2a: Surface
- 3: Cell culture scaffold material

CLAIMS

Claim 1. A cell culture scaffold material, comprising
a peptide-conjugated polyvinyl alcohol derivative having a
5 polyvinyl alcohol derivative portion and a peptide portion,
the cell culture scaffold material having a hydroxyl
value of 1,100 mgKOH/g or less.

Claim 2. A cell culture scaffold material, comprising
10 a peptide-conjugated polyvinyl alcohol derivative having a
polyvinyl alcohol derivative portion and a peptide portion,
the peptide-conjugated polyvinyl alcohol derivative
having a hydroxyl value of 1,100 mgKOH/g or less.

15 Claim 3. The cell culture scaffold material according
to claim 1 or 2, wherein the peptide portion has a cell-
adhesive amino acid sequence.

Claim 4. The cell culture scaffold material according
20 to claim 3, wherein the cell-adhesive amino acid sequence
has at least an RGD sequence, a YIGSR sequence, or a PDSGR
sequence.

Claim 5. The cell culture scaffold material according
25 to claim 3 or 4, wherein the cell-adhesive amino acid

sequence has at least the RGD sequence represented by
Formula (1) below:

Arg-Gly-Asp-X ... Formula (1)

In Formula (1) above, X represents Gly, Ala, Val, Ser,
5 Thr, Phe, Met, Pro, or Asn.

Claim 6. The cell culture scaffold material according
to any one of claims 1 to 5, wherein the peptide portion is
composed of 3 or more and 10 or less amino acids.
10

Claim 7. The cell culture scaffold material according
to any one of claims 1 to 6, wherein the polyvinyl alcohol
derivative portion and the peptide portion are bound via a
linker portion.
15

Claim 8. The cell culture scaffold material according
to any one of claims 1 to 7, wherein the peptide-conjugated
polyvinyl alcohol derivative is a peptide-conjugated
polyvinyl acetal resin having a polyvinyl acetal resin
20 portion and the peptide portion.

Claim 9. A cell culture vessel, comprising a vessel
body and
the cell culture scaffold material according to any
25 one of claims 1 to 8,

the cell culture scaffold material being arranged on a surface of the vessel body.
