ABSTRACT

An object of the invention is to provide a trading system used by agents or the like when placing orders in a trading market system. The trading system has order receiving means; order ID assigning means; event monitoring means for monitoring at least one event and determining whether order conditions have been met; order issuing means for issuing, in the trading market system, order attributes defined on the basis of order attributes; and order attribute definition means for performing processing on the basis of objects when undefined order attributes are included, and returning the results. The order issuing means transfers an object ID included in the undefined order attributes; the order attribute definition means processes the object and returns the results to the order issuing means; and the order issuing means receives the processed results, converts the portion of the undefined order attributes to the processed results, and converts the order attributes to defined order attributes, whereupon the defined order attributes are issued to the trading market system.
