

Description

This invention relates to color picture tubes having multibeam electron guns and, particularly, to an improvement in such guns to reduce the convergence drift of the electron beams during tube warmup.

5 The most common multibeam electron gun presently used in color picture tubes is the inline electron gun. An inline electron gun is one designed to generate or initiate preferably three electron beams in a common plane and direct those beams along convergent paths in that plane, to a point or small area of convergence at the tube screen.

10 Most inline electron guns attain static convergence of the undeflected electron beams by slightly distorting the focus fields at the outer beams, so that the outer beams are deflected toward the center beam to effect convergence of the beams at the screen. One means of distorting the focus fields is to offset one aperture in a focus electrode from its associated aperture in a facing focus electrode. A given static convergence at the screen of a tube is established by a particular combination of aperture offsets throughout the gun and beam position in the main lens. A problem, encountered in color picture tubes having built-in static convergence, is convergence drift during tube warm-up. Convergence drift is caused by a change of beam position in the main lens due to a relative change of horizontal aperture positions of all the electrodes throughout the electron gun. The relative aperture motion is due to different thermal expansions of the different grids caused by a temperature gradient from the cathode to the main lens. The convergence drift problem has been approached previously by tailoring the coefficient of expansion of each electrode, to match the thermal gradient, to keep constant the relative horizontal positions of all apertures throughout the gun. Such a modified electron gun is disclosed in U.S. Patent No. 4,631,442, issued to Reule et al. on December 23, 1986.

20 As part of the present invention, it first was determined that simply matching the coefficients of expansion of the electrodes to the thermal gradient in an electron gun does not always provide the desired reduction in convergence drift. Instead, it was determined that a more detailed analysis of the gun structure can be used to attain an even greater reduction in convergence drift.

25 A color picture tube according to the invention includes a screen and an improved inline gun for generating and directing three inline electron beams along separate paths toward the screen. The gun includes a plurality of cathodes and at least six electrodes longitudinally spaced from the cathodes. The first, second and fourth electrodes from the cathodes are of materials having lower coefficients of thermal expansion than the coefficients of thermal expansion of the materials of the other electrodes.

FIGURE 14 is a composite graph comparing the outer-to-outer beam convergence drift for tubes having a standard unmodified gun, a gun with a low expansion G2, a gun with a low expansion G4 and a gun with combined low expansion G2 and G4 electrodes.

FIGURE 1 is a plan view of a rectangular color picture tube 10 having a glass envelope comprising a rectangular faceplate panel or cap 12 and a tubular neck 14 connected by a rectangular funnel 16. The panel comprises a viewing faceplate 18 and a peripheral flange or sidewall 20 which is sealed to the funnel 16. A three-color phosphor screen 22 is carried by the inner surface of the faceplate 18. The screen is preferably a line screen, with the phosphor lines extending substantially perpendicular to the high-frequency raster line scan of the tube (normal to the plane of FIGURE 1). A multi-apertured color-selection electrode or shadow mask 24 is removably mounted in predetermined spaced relation to the screen 22. An improved inline electron gun 26, shown schematically by dotted lines in FIGURE 1, is centrally mounted within the neck 14, to generate and direct three electron beams 28 along coplanar convergent paths through the mask 24 to the screen 22.

The tube of FIGURE 1 is designed to be used with an external magnetic deflection yoke, such as the self-converging yoke 30 shown surrounding the neck 14 and funnel 16 in the neighborhood of their junction. When activated, the yoke 30 subjects the three beams 28 to vertical and horizontal magnetic flux which cause the beams to scan horizontally and vertically, respectively, in a rectangular raster over the screen 22. The initial plane of deflection (at zero deflection) is shown by the line P-P in FIGURE 1 at about the middle of the yoke 30. Because of fringe fields, the zone of deflection of the tube extends axially, from the yoke 30 into the region of the electron gun 26. For simplicity, the actual curvature of the deflected beam paths in the deflection zone is not shown in FIGURE 1.

The details of the electron gun 26 are shown in FIGURES 2 and 3. The electron gun comprises two glass supports rods 32 on which various electrodes are mounted. These electrodes include three equally spaced coplanar cathodes 34 (one for each beam), a G1 grid electrode 36, a G2 grid electrode 38, a G3 electrode 40, a G4 electrode 42, a G5 electrode 44, and a G6 electrode 46, spaced along the glass rods 32 in the order named. Each of the electrodes following the cathodes has three inline apertures therein to permit passage of three coplanar electron beams. The G1 grid electrode 36 and the G2 grid electrode 38 are parallel flat plates that can include embossings therein for added strength. Three inline apertures 48 (one shown) are located in the G1 grid electrode 36, and three apertures 54 (one shown) are located in the G2 grid electrode 38. The G3 electrode 40 is formed by the two cup-shaped elements 60 and 62, each having apertured bottoms. The apertured bottom of the element 60 faces the G2 grid electrode 38, and the open end of the element 60 is attached to the open end of the element 62. The G4 electrode 42 is a plate having three apertures 61 (one shown) therein. The G5 electrode 44 is formed by two cup-shaped elements 68 and 70. Each of the closed ends of the elements 68 and 70 includes three apertures, and the open ends of the elements 68 and 70 are connected. The G6 electrode 46 also includes two cup-shaped elements 72 and 73 having apertured bottoms. A shield cup 75 is attached to the outside bottom of the element 73.

The facing closed ends of the G5 electrode 44 and the G6 electrode 46, as shown in FIGURE 3, have large recesses 76 and 78, respectively, therein. The recesses 76 and 78 set back a portion of the closed end of the G5 electrode 44 that contains three apertures 82 from a portion of the closed end of the G6 electrode 46 that contains three apertures 88. The remaining portions of the closed ends of the G5 electrode 44 and the G6 electrode 46 form rims 92 and 94, respectively, that extend peripherally around the recesses 76 and 78. The rims 92 and 94 are the closest portions of the two electrodes 44 and 46 to each other. The configuration of the recess 78 in the G6 electrode 46 is different from that of the recess 76 in the G5 electrode 44. The recess 78 is narrower at the center aperture than at the side apertures, whereas the recess 76 is uniform in width at the three apertures therein.

The G4 electrode 42 is electrically connected to the G2 electrode 38 by a lead 96, and the G3 electrode 40 is electrically connected to the G5 electrode 44 by a lead 98, as shown in FIGURE 3. Separate leads (not shown) connect the G3 electrode 40, the G2 electrode 38, the G1 electrode 36, the cathodes 34 and the cathode heaters to a base 100 (shown in FIGURE 1) of the tube 10, so that these components can be electrically activated. Electrical activation of the G6 electrode 46 is obtained by a contact between the shield cup 75 and a conductive coating internal to the tube which is electrically connected to an anode button extending through the funnel 16. (The coating and anode button are not shown.)

In the electron gun 26, the cathodes 34, the G1 electrode 36 and the G2 electrode 38 comprise the beam-forming region of the gun. During tube operation, modulated control voltages are applied to the cathodes 34, the G1 electrode 36 is grounded, and a relatively low positive voltage (e.g., 800 to 1100 volts) is applied to the G2 electrode 38. The G3 electrode 40, the G4 electrode 42, and the facing portion of the G5 electrode 44 comprise a prefocusing lens portion of the electron gun 26. During tube operation, a focus voltage is applied to both the G3 electrode 40 and to the G5 electrode 44. The facing portions of the G5 electrode 44 and the G6 electrode 46 comprise the main focus lens of the electron gun 26. During tube operation, an anode voltage is applied to the G6 electrode 46 so that a bipotential focus lens is formed between the G5 and G6 electrodes.

Some typical dimensions for the electron gun 26 of FIGURE 2 are presented in the following table.

TABLE

	External diameter of tube neck	29.00 mm.
5	Internal diameter of tube neck	24.00 mm.
	Spacing between G1 and G2 electrodes	0.18 mm.
	Spacing between G2 and G3 electrodes	1.19 mm.
	Spacing between G3 and G4 electrodes	1.27 mm.
	Spacing between G4 and G5 electrodes	1.27 mm.
10	Spacing between G5 and G6 electrodes	1.27 mm.
	Center-to-Center spacing between adjacent apertures in G5 electrode	5.08 mm.
	Diameter of Apertures in G5 and G6 electrodes	4.06 mm.
15	Depth of recess in G5 electrode	2.03 mm.
	Thickness of G1 electrode	0.10 mm.
	Thickness of G2 electrode	0.25 to 0.50 mm.
	Thickness of G3 electrode	7 mm.
	Length of G4 electrode	0.51 to 1.78 mm.
20	Length of G5 electrode	17.22 mm.
	Focus voltage	7.8 to 9.5 kV
	Anode voltage	25 kV

In the above-described electron gun 26, the G1 electrode 36, the G2 electrode 38 and the G4 electrode 42 are constructed of a material having a lower coefficient of thermal expansion, less than $10 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$, than do the materials used to construct the other electrodes. Preferably, the G1 electrode 36, the G2 electrode 38 and the G4 electrode 42 are made from 430 stainless steel, which is a magnetically permeable material having a coefficient of thermal expansion of about $9 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$. The bottom portion or G2-facing side of the G3 electrode 40 is made from a 52% nickel alloy, which is also magnetically permeable and has a coefficient of thermal expansion of about $9.5 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$. The top portion of the G3 electrode 40, the G5 electrode 44 and the G6 electrode 46 are made from 305 stainless steel, which is nonmagnetic and has a coefficient of thermal expansion of about $20 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$. The purpose and results of using these materials of different coefficients of thermal expansion are discussed below.

35 Design Method

The convergence drift of a standard unmodified electron gun of the same type as disclosed in FIGURE 2 is shown in FIGURE 4. The drift between the blue and red beams does not decrease to less than 0.1 mm until about 20 minutes. First, it is desirable to reduce the time that it takes for the convergence drift to decrease below 0.1 mm, but, preferably, it is desirable to design an electron gun wherein the convergence drift never exceeds 0.1 mm.

The improved electron gun was designed by analyzing the motion of each electrode in the gun during tube warmup and then by determining the sensitivity of electron beam motion to the horizontal motion of the apertures in each electrode. Once this sensitivity was established, it then was determined how to alter the aperture motion of selected electrodes to reduce convergence drift through the use of different thermal expansion materials.

In doing the analysis, a computer program was used that simulated the electron beam trajectories. After the analysis, actual tubes were built and tested to verify the analytical results.

50 Electron Gun Analysis

Utilizing the computer program, the horizontal positions of the outer apertures in each electrode were independently changed in 0.002 inch (0.05 mm) increments. From this, the sensitivity of electron beam motion at the screen to the aperture motion was determined for each electrode. The beam motion at the screen caused by the expansion of each electrode during tube warmup was then determined by translating the temperature rise of each electrode, as a function of time, into aperture motion, based on the thermal coefficient of expansion of the electrode material. Using the transient temperature rise of each electrode during warm-up, shown in FIGURE 5, and the sensitivity of beam motion on the screen due to the 0.002 inch (0.05 mm) change in hor-

zontal aperture position of each electrode, the beam motion on the screen for each electrode during warm-up was determined to be as shown in FIGURE 6. By normalizing these curves to the steady-state converged beams, as shown in FIGURE 7, the contribution to convergence drift of each electrode can be seen. Because the two outer beams (red/blue) have equal but opposite motion during warm-up, the red-to-blue convergence drift is twice that of a single beam, as shown in FIGURE 8. Summing the contributions of each grid at specific times resulted in the theoretical red-to-blue convergence drift shown in FIGURE 9.

Because the net peak convergence drift is +0.32 mm (FIGURE 9), convergence drift can be reduced by reducing positive beam motion components. Referring to FIGURE 8, this was achieved by making the G2 and G4 electrodes from materials having substantially lower coefficients of thermal expansion than the thermal expansion coefficients of the G5 and G6 electrode materials, e.g., about $9 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$ versus about $20 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$. The theoretical results of using only a low expansion G2, only a low expansion G4, and both a low expansion G2 and G4 (compared to a standard electron gun having 305 stainless steel G2 and G4 electrodes) are shown in FIGURE 10. From this figure, it can be seen that the increasing order of improvement is, as expected, with the low expansion G2, then the low expansion G4, and then the combination low expansion G2 and G4. With the combination low expansion G2 and G4, settling of the convergence drift to within 0.1 mm of the steady-state convergence value occurs within 1.5 minutes, as compared to 13 minutes for the standard electron gun.

It should be noted that convergence drift could also have been improved by using a low expansion G5 top in place of the low expansion G4 (See FIGURE 8). However, this would not be desirable, because low expansion materials are usually magnetic. The G5 is located in the tube such that, if it were magnetic, it would render other components, such as external beam benders on the neck, less effective and would increase yoke drive requirements.

The bottom portion or G2-facing side of the G3 is made of a magnetically permeable material, to act as a shield to prevent penetration of the deflection fields into the beam-forming region of the electron gun. Such magnetically permeable materials have lower coefficients of thermal expansion and are used, even though the electron gun analysis indicates that a higher coefficient of thermal expansion material would be preferable from the beam convergence standpoint.

Similarly, the G1 is constructed of a low expansion material, even though the analysis indicates that a higher expansion material should be used, because of its close proximity to the cathodes. Large expansion of the G1 may cause it to warp, because it is a thin flat electrode.

Experimental Results

Based on the theoretical analysis of red-to-blue convergence drift in the electron gun, three guns were fabricated having low expansion G2 electrodes, three guns were fabricated with low expansion G4 electrodes, and three guns were fabricated having both low expansion G2 and G4 electrodes, e.g., about $9 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$. The convergence drift results of these electron gun configurations are shown in FIGURES 11a-c 12a-c and 13a-c, respectively. A comparative summary of the standard and the modified guns, of FIGURES 11a-c, 12a-c and 13a-c, is shown in FIGURE 14. As seen in FIGURE 14, the relative convergence drift performance of the experimental tubes is the same as that calculated in the theoretical analysis for low expansion G2 and G4 electrodes. The time to settle within 0.1 mm of the steady-state convergence is less than 2 minutes, as compared to 18 minutes for the standard gun.

Although the above method, of determining which electrode or electrodes of an electron gun should be constructed of a material having a lower coefficient of thermal expansion, was described for an electron gun having six electrodes and particular electrical connections, the method also may be applied to other electron guns having more than six electrodes and different electrical connections.

Claims

1. A color picture tube including a screen and an inline electron gun for generating and directing three inline electron beams along separate paths toward said screen, said electron gun comprising a plurality of cathodes and at least six electrodes longitudinally spaced from said cathodes, characterized by the first (36), second (38) and fourth (42) electrodes from said cathodes (34) are of materials having lower coefficients of thermal expansion than the coefficients of thermal expansion of the materials of the other electrodes (40,44,46).
2. The tube as defined in claim 1, characterized in that the first (36), second (38) and fourth (42) electrodes

zontal aperture position of each electrode, the beam motion on the screen for each electrode during warm-up was determined to be as shown in FIGURE 6. By normalizing these curves to the steady-state converged beams, as shown in FIGURE 7, the contribution to convergence drift of each electrode can be seen. Because the two outer beams (red/blue) have equal but opposite motion during warm-up, the red-to-blue convergence drift is twice that of a single beam, as shown in FIGURE 8. Summing the contributions of each grid at specific times resulted in the theoretical red-to-blue convergence drift shown in FIGURE 9.

Because the net peak convergence drift is +0.32 mm (FIGURE 9), convergence drift can be reduced by reducing positive beam motion components. Referring to FIGURE 8, this was achieved by making the G2 and G4 electrodes from materials having substantially lower coefficients of thermal expansion than the thermal expansion coefficients of the G5 and G6 electrode materials, e.g., about $9 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$ versus about $20 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$. The theoretical results of using only a low expansion G2, only a low expansion G4, and both a low expansion G2 and G4 (compared to a standard electron gun having 305 stainless steel G2 and G4 electrodes) are shown in FIGURE 10. From this figure, it can be seen that the increasing order of improvement is, as expected, with the low expansion G2, then the low expansion G4, and then the combination low expansion G2 and G4. With the combination low expansion G2 and G4, settling of the convergence drift to within 0.1 mm of the steady-state convergence value occurs within 1.5 minutes, as compared to 13 minutes for the standard electron gun.

It should be noted that convergence drift could also have been improved by using a low expansion G5 top in place of the low expansion G4 (See FIGURE 8). However, this would not be desirable, because low expansion materials are usually magnetic. The G5 is located in the tube such that, if it were magnetic, it would render other components, such as external beam benders on the neck, less effective and would increase yoke drive requirements.

The bottom portion or G2-facing side of the G3 is made of a magnetically permeable material, to act as a shield to prevent penetration of the deflection fields into the beam-forming region of the electron gun. Such magnetically permeable materials have lower coefficients of thermal expansion and are used, even though the electron gun analysis indicates that a higher coefficient of thermal expansion material would be preferable from the beam convergence standpoint.

Similarly, the G1 is constructed of a low expansion material, even though the analysis indicates that a higher expansion material should be used, because of its close proximity to the cathodes. Large expansion of the G1 may cause it to warp, because it is a thin flat electrode.

Experimental Results

Based on the theoretical analysis of red-to-blue convergence drift in the electron gun, three guns were fabricated having low expansion G2 electrodes, three guns were fabricated with low expansion G4 electrodes, and three guns were fabricated having both low expansion G2 and G4 electrodes, e.g., about $9 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$. The convergence drift results of these electron gun configurations are shown in FIGURES 11a-c 12a-c and 13a-c, respectively. A comparative summary of the standard and the modified guns, of FIGURES 11a-c, 12a-c and 13a-c, is shown in FIGURE 14. As seen in FIGURE 14, the relative convergence drift performance of the experimental tubes is the same as that calculated in the theoretical analysis for low expansion G2 and G4 electrodes. The time to settle within 0.1 mm of the steady-state convergence is less than 2 minutes, as compared to 18 minutes for the standard gun.

Although the above method, of determining which electrode or electrodes of an electron gun should be constructed of a material having a lower coefficient of thermal expansion, was described for an electron gun having six electrodes and particular electrical connections, the method also may be applied to other electron guns having more than six electrodes and different electrical connections.

Claims

1. A color picture tube including a screen and an inline electron gun for generating and directing three inline electron beams along separate paths toward said screen, said electron gun comprising a plurality of cathodes and at least six electrodes longitudinally spaced from said cathodes, characterized by the first (36), second (38) and fourth (42) electrodes from said cathodes (34) are of materials having lower coefficients of thermal expansion than the coefficients of thermal expansion of the materials of the other electrodes (40,44,46).
2. The tube as defined in claim 1, characterized in that the first (36), second (38) and fourth (42) electrodes

from said cathodes (34) are of magnetically permeable materials, and at least two of the other electrodes (40,44,46) are of nonmagnetic materials.

- 5 3. The tube as defined in claim 1, characterized by the four electrodes (36,38,40,42) closest to said cathodes (34) being of materials having low coefficients of thermal expansion below $10 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$, and the remaining electrodes (44,46) being of materials having higher coefficients of thermal expansion that are at least twice as large as the highest coefficient of thermal expansion of the four electrodes closest to said cathodes.
- 10 4. The tube as defined in claim 1 or 3, characterized in that said second (38) and fourth (42) electrodes from said cathodes (34) are electrically connected.
5. The tube as defined in claim 4, characterized in that a third electrode (40) from said cathodes (34) is electrically connected to a fifth electrode (44) from said cathodes.
- 15 6. The tube as defined in claim 3, characterized in that the first (36), second (38), third (40) and fourth (42) electrodes from said cathodes (34) are each at least partly made of magnetically permeable materials, and the other electrodes (44,46) are of nonmagnetic materials.
- 20 7. The tube as defined in claim 1, characterized by the second (38) and fourth (42) electrodes from said cathodes (34) being electrically connected, the third (40) and fifth (44) electrodes from said cathodes being electrically connected, the first (36), second (38) and fourth (42) electrodes from said cathodes being of a material having a coefficient of thermal expansion of about $9 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$, and the remaining electrodes (40,44,46) being of materials having higher coefficients of thermal expansion.
- 25 8. The tube as defined in claim 7, characterized by the fifth (44) and sixth (46) electrodes from said cathodes (34) are of materials having a coefficient of thermal expansion of about $20 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$.
- 30 9. The tube as defined in claim 7 or 8, characterized in that a portion (60) of the third electrode (40) from said cathodes (34) that faces the second electrode (38) is of a material having a coefficient of thermal expansion of about $9.5 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$.
- 35 10. The tube as defined in claim 7, 8 or 9, characterized in that a portion (62) of the third electrode (40) from said cathodes (34) that faces the fourth electrode (42) is of a material having a coefficient of thermal expansion of about $20 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$.

Patentansprüche

- 40 1. Farbbildröhre mit einem Schirm und einer Inline-Elektronenkanone, um drei in Reihe liegende Elektronenstrahlen zu erzeugen und entlang getrennter Wege auf den Schirm zu richten, wobei die Elektronenkanone eine Vielzahl von Kathoden und wenigstens sechs in Längsrichtung einen Abstand von den Kathoden aufweisende Elektroden umfaßt, dadurch gekennzeichnet, daß von den Kathoden (34) aus die erste (36), die zweite (38) und die vierte (42) Elektrode aus Materialien bestehen, die niedrigere thermische Ausdehnungskoeffizienten haben als die Materialien der anderen Elektroden (40, 44, 46).
- 45 2. Röhre nach Anspruch 1, dadurch gekennzeichnet, daß von den Kathoden (34) aus die erste (36), die zweite (38) und die vierte (42) Elektrode aus magnetisch permeablen Materialien bestehen und wenigstens zwei der anderen Elektroden (40, 44, 46) aus nicht-magnetischen Materialien bestehen.
- 50 3. Röhre nach Anspruch 1, dadurch gekennzeichnet, daß die vier den Kathoden (34) am nächsten liegen Elektroden (36, 38, 40, 42) aus Materialien mit niedrigen thermischen Ausdehnungskoeffizienten unter $10 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$ bestehen, und daß die übrigen Elektroden (44, 46) aus Materialien mit höheren thermischen Ausdehnungskoeffizienten bestehen, die wenigstens zweimal so groß wie der höchste thermische Ausdehnungskoeffizient der vier den Kathoden am nächsten liegenden Elektroden ist.
- 55 4. Röhre nach Anspruch 1 oder 3, dadurch gekennzeichnet, daß von den Kathoden (34) aus die zweite (38) und vierte (42) Elektrode elektrisch miteinander verbunden sind.

5. Röhre nach Anspruch 4, dadurch gekennzeichnet, daß von den Kathoden aus eine dritte Elektrode (40) mit einer von den Kathoden (34) aus fünften Elektrode (44) verbunden ist.
- 5 6. Röhre nach Anspruch 3, dadurch gekennzeichnet, daß die erste (36), zweite (38), dritte (40) und vierte (42) Elektrode der Kathoden (34) jeweils wenigstens teilweise aus magnetisch permeablem Material und die anderen Elektroden (44, 46) aus nichtmagnetischem Material sind.
- 10 7. Röhre nach Anspruch 1, dadurch gekennzeichnet, daß die zweite (38) und die vierte (42) Elektrode besagter Kathoden (34) elektrisch miteinander verbunden sind, daß die dritte (40) und die fünfte (44) Elektrode der Kathoden miteinander elektrisch verbunden sind, daß die erste (36), die zweite (38) und die vierte (42) Elektrode besagter Kathoden aus einem Material bestehen, das einen thermischen Ausdehnungskoeffizienten von ungefähr $9 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$ hat, und daß die verbleibenden Elektroden (40, 44, 46) aus einem Material bestehen, das einen höheren Ausdehnungskoeffizienten hat.
- 15 8. Röhre nach Anspruch 7, dadurch gekennzeichnet, daß die fünfte (44) und sechste (46) Elektrode der Kathoden (34) aus Materialien sind, die einen Ausdehnungskoeffizienten von ungefähr $20 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$ haben.
- 20 9. Röhre nach Anspruch 7 oder 8, dadurch gekennzeichnet, daß ein Teil (60) der dritten Elektrode (40) der Kathoden (34), der der zweiten Elektrode (38) zugewandt ist, aus einem Material ist, das einen Ausdehnungskoeffizienten von ungefähr $9,5 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$ hat.
- 25 10. Röhre nach Anspruch 7, 8 oder 9, dadurch gekennzeichnet, daß ein Teil (42) der dritten Elektrode (40) der Kathoden (34), der der vierten Elektrode (42) zugewandt ist, aus einem Material ist, das einen Ausdehnungskoeffizienten von ungefähr $20 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$ hat.

Revendications

- 30 1. Tube image couleur comportant un écran et un canon électronique en ligne pour générer et diriger trois faisceaux électroniques en ligne le long de trajectoires séparées vers ledit écran, ledit canon électronique comprenant une pluralité de cathodes et au moins six électrodes longitudinalement espacées desdites cathodes, caractérisé en ce que les première (36), seconde (38) et quatrième (42) électrodes desdites cathodes (34) sont en des matériaux présentant des coefficients de dilatation thermique inférieurs aux coefficients de dilatation thermique des matériaux des autres électrodes (40, 44, 46).
- 35 2. Tube tel que défini dans la revendication 1, caractérisé en ce que la première (36), la seconde (38) et la quatrième électrodes desdites cathodes (34) sont en des matériaux magnétiquement perméables et au moins deux des autres électrodes (40, 44, 46) sont en matériaux non magnétiques.
- 40 3. Tube tel que défini dans la revendication 1, caractérisé en ce que les quatre électrodes (36, 38, 40, 42) les plus proches desdites cathodes (34) sont en des matériaux présentant de faibles coefficients de dilatation thermique inférieurs à $10 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$ et les électrodes restantes (44, 46) sont en des matériaux présentant des coefficients de dilatation thermique plus élevés, qui sont au moins deux fois plus importants que le coefficient de dilatation thermique le plus élevé des quatre électrodes les plus proches desdites cathodes.
- 45 4. Tube tel que défini dans la revendication 1 ou 3, caractérisé en ce que ladite seconde (38) et la quatrième (42) électrodes desdites cathodes (34) sont électriquement connectées.
- 50 5. Tube tel que défini dans la revendication 4, caractérisé en ce qu'une troisième électrode (40) desdites cathodes (34) est électriquement connectée à une cinquième électrode (44) desdites cathodes.
- 55 6. Tube tel que défini dans la revendication 3, caractérisée en ce que la première (36), la seconde (38), la troisième et la quatrième (42) électrodes desdites cathodes (34) sont chacune constituée, au moins partiellement, de matériaux magnétiquement perméables, et les autres électrodes (44, 46) sont en matériaux non magnétiques.

- 5 7. Tube tel que défini dans la revendication 1, caractérisé en ce que les seconde (38) et quatrième (42) électrodes desdites cathodes (34) sont électriquement connectées, les troisième (40) et cinquième (44) électrodes desdites cathodes sont électriquement connectées, les première (36), seconde (38) et quatrième (42) électrodes desdites cathodes sont en matériau présentant un coefficient de dilatation thermique d'environ $9 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$, et les électrodes restantes (40, 44, 46) sont en des matériaux présentant des coefficients de dilatation thermique plus élevés.
- 10 8. Tube tel que défini dans la revendication 7, caractérisé en ce que la cinquième (44) et la sixième (46) électrodes desdites cathodes (34) sont en des matériaux présentant un coefficient de dilatation thermique d'environ $20 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$.
- 15 9. Tube tel que défini dans la revendication 7 ou 8, caractérisé en ce qu'une portion (60) de la troisième électrode (40) desdites cathodes (34) qui fait face à la seconde électrode (38) est en un matériau présentant un coefficient de dilatation thermique d'environ $9,5 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$.
- 20 10. Tube tel que défini dans les revendications 7, 8 ou 9 caractérisé en ce qu'une portion (62) de la troisième électrode (40) desdites cathodes (34) qui fait face à la quatrième électrode (42) est en un matériau présentant un coefficient de dilatation thermique d'environ $20 \times 10^{-6} \text{ }^{\circ}\text{C}^{-1}$.
