

[Specification]

[Title of the Invention]

ROTARY ELECTRIC MACHINE

[Technical Field of the Invention]

5 [0001]

The present invention relates to a rotary electric machine.

The present application claims priority based on Japanese Patent Application No. 2022-053591 filed in Japan on March 29, 2022, the contents of which are incorporated herein by reference.

10 [Related Art]

[0002]

Conventionally, for example, a rotary electric machine described in Patent Document 1 below is known.

[Summary of Invention]

20 [Problems to be Solved by the Invention]

[0004]

Since an interior permanent magnet synchronous motor (IPMSM) of this type is operated by utilizing a magnetic flux of a permanent magnet, a high voltage is required in a high-speed operation region due to an effect of a counter electromotive force by the magnet. Therefore, by increasing the advance angle and using the field weakening

25

operation, the magnet magnetic flux is offset by the field magnetic flux to reduce the voltage.

However, when the motor is operated in the advance angle region exceeding the optimum advance angle, the torque rapidly decreases.

5 Thus, when the field weakening operation is performed as described above, the output torque may decrease, for example, when the motor is operated in a region where the advance angle is too large to exceed the optimum advance angle.

[0005]

 The present invention has been made in view of the above circumstances, and an
10 object is to improve torque with respect to a voltage.

[Means for Solving the Problem]

[0006]

 <1> A rotary electric machine according to an aspect of the present invention is a rotary electric machine including: a stator having an annular shape; and a rotor that is
15 disposed in the stator, in which the rotor includes: a rotor core; and a plurality of sets of permanent magnets embedded in the rotor core, each set of the permanent magnets constituting one magnetic pole, the plurality of sets of the permanent magnets disposed in the rotor core in a circumferential direction of the rotor core, the rotor core includes: a first flux barrier provided on both sides in a rotation direction of the rotor with respect to
20 each set of the permanent magnets; and a first bridge provided outside the rotor core in a radial direction with respect to the first flux barrier, and the first bridge includes: a front bridge provided at a front in the rotation direction of the rotor; and a rear bridge provided at a rear in the rotation direction of the rotor, and in which when a front reference location that is a reference location of the front bridge is an intersection point of a front
25 imaginary line passing through a center axis of the rotor core and a front end of each set

of the permanent magnets and an outer circumferential surface of the rotor core in a plane view in which the rotor is viewed from an axial direction, and a rear reference location that is a reference location of the rear bridge is an intersection point of a rear imaginary line passing through the center axis of the rotor core and a rear end of each set of the permanent magnets and the outer circumferential surface of the rotor core in the plane view, in at least one set of the permanent magnets among the plurality of sets of the permanent magnets, a front end of the rear bridge is disposed at a position away from the rear reference location to the front by θ_f (radian) at a central angle about the center axis, and a rear end of the front bridge is disposed at a position away from the front reference location to the front by 0 (radian) or more and θ_f (radian) or less at the central angle about the center axis.

θ_f satisfies Formulae (1) and (2) described below.

$$0 < \theta_f \leq (\theta_a/8) \dots (1)$$

$$\theta_a = 2\pi/(N_{\text{slot}}) \dots (2)$$

Here, N_{slot} in Formula (2) described above means the number of slots of the stator. In addition, one set of permanent magnets includes one or more permanent magnets. Further, the rear end of the front bridge and the front end of the rear bridge are portions of the bridges where magnetic saturation of the magnetic flux generated by each set of permanent magnets occurs. In other words, the rear end of the front bridge and the front end of the rear bridge are portions of the bridges where the magnetic flux starts to cross from the rotor to the stator.

[0007]

<2> The rotary electric machine according to <1> may adopt a constitution in which in the at least one of the plurality of sets of the permanent magnets, the rear end of the front bridge is disposed at the front reference location, and the front end of the rear

bridge is disposed at a position away from the rear reference location to the front by $\theta_a/12$ (radian) at the central angle about the center axis.

[0008]

<3> The rotary electric machine according to <1> or <2> may adopt a constitution in which two permanent magnets form a set to constitute one magnetic pole, each set of the permanent magnets includes a front magnet positioned at the front and a rear magnet positioned at the rear, the front magnet and the rear magnet are disposed in a V shape protruding inward in the radial direction in the plane view, the front bridge is provided in front of the front magnet, the rear bridge is provided in the rear of the rear magnet, and in the plane view, the front imaginary line passes through the center axis and a front end of the front magnet, and the rear imaginary line passes through the center axis and a rear end of the rear magnet.

[0009]

The inventor of the present application has found that the circumferential position of the rear end of the front bridge and the circumferential position of the front end of the rear bridge, in other words, the start position of the first bridge affects the size of the optimum advance angle.

Therefore, the inventor of the present application intensively studied the circumferential position of the rear end of the front bridge and the circumferential position of the front end of the rear bridge in units of θ_a (radian) at the central angle corresponding to the pitch of the teeth of the stator, and found that by setting as described above, high torque can be output while utilizing the voltage reduction effect at the increased advance angle.

Note that magnetic saturation occurs at the start position of the first bridge in the process of transmitting the magnetic flux generated in the magnetic pole constituted by

one set of permanent magnets in the rotor core. Then, the magnetic flux flows from the inside to the outside of the rotor core and is transmitted to the teeth of the stator.

Therefore, the start position of the first bridge is a starting point at which the magnetic flux is transmitted to the stator. The fact that the start position of the first bridge is the starting point in this manner is considered to be related to the fact that the start position of the first bridge affects the size of the optimum advance angle.

[Effects of the Invention]

[0010]

According to the present invention, it is possible to improve the torque with respect to the voltage.

[Brief Description of the Drawing(s)]

[0011]

FIG. 1 is a diagram illustrating a rotary electric machine according to an embodiment of the present invention, and is a plan diagram including a partial cross section.

FIG. 2 is an enlarged plan diagram of a stator and a rotor included in the rotary electric machine illustrated in FIG. 1.

FIG. 3 is an enlarged plan diagram of the rotor included in the rotary electric machine illustrated in FIG. 1.

FIG. 4 is an enlarged plan diagram of a portion IV illustrated in FIG. 3.

FIG. 5 is an enlarged plan diagram of a portion V illustrated in FIG. 3.

FIG. 6 is a diagram showing the rotary electric machine illustrated in FIG. 1, and is an enlarged plan diagram illustrating a state in which a rear end of a front bridge and a front end of a rear bridge of the rotor are positioned at respective reference locations.

FIG. 7 is a diagram showing the rotary electric machine illustrated in FIG. 1, and

is an enlarged plan diagram illustrating a state in which the rear end of the front bridge and the front end of the rear bridge of the rotor are moved to the front as compared with the positions illustrated in FIG. 5.

FIG. 8 is a diagram showing the rotary electric machine illustrated in FIG. 1, and
5 is an enlarged plan diagram illustrating a state in which the rear end of the front bridge and the front end of the rear bridge of the rotor are moved to the front as compared with the positions illustrated in FIG. 6.

FIG. 9 is a diagram showing the rotary electric machine illustrated in FIG. 1, and
is an enlarged plan diagram illustrating a state in which the rear end of the front bridge
10 and the front end of the rear bridge of the rotor are moved to the front as compared with the positions illustrated in FIG. 7.

FIG. 10 is a diagram showing the rotary electric machine illustrated in FIG. 1,
and is an enlarged plan diagram illustrating a state in which the rear end of the front
bridge and the front end of the rear bridge of the rotor are moved to the front as
15 compared with the positions illustrated in FIG. 5.

FIG. 11 is a diagram illustrating an image in which a magnetic flux flows in the rotary electric machine according to an embodiment of the present invention.

[Embodiment(s) of the Invention]

[0012]

20 Hereinafter, a rotary electric machine according to an embodiment of the present invention will be described with reference to FIGS. 1 to 11. The rotary electric machine is an electric motor, specifically, an AC electric motor, more specifically, a synchronous electric motor, and still more specifically, a permanent magnet field type electric motor. This type of electric motor is suitably adopted in, for example, an electric vehicle.

25 [0013]

As illustrated in FIGS. 1 and 2, a rotary electric machine 10 includes a stator 20, a rotor 30, a case 50, and a rotary shaft 60. The stator 20 and the rotor 30 are housed in the case 50. The stator 20 is fixed to the case 50. The rotary electric machine 10 is of an inner rotor type in which the rotor 30 is positioned inside the stator 20.

5 [0014]

Note that, in the present embodiment, the rotary electric machine 10 is a three-phase AC motor having 8 poles and 24 slots. However, for example, the number of poles, the number of slots, the number of phases, and the like can be appropriately changed.

10 In addition, in the rotary electric machine 10, the axes of the stator 20 and the rotor 30 are on a common axis. Hereinafter, this common axis is referred to as a central axis O (center axis of the rotor 30). A direction of the central axis O (an axial direction of a rotor core 31 to be described below) is referred to as an axial direction, a direction orthogonal to the central axis O (a radial direction of the rotor core 31 to be described
15 below) is referred to as a radial direction, and a direction circling around the central axis O (a circumferential direction of the rotor core 31 to be described below) is referred to as a circumferential direction.

[0015]

The stator 20 includes a stator core 21 and a winding, which is not illustrated.

20 The stator core 21 includes a core back 22 (yoke) having a cylindrical shape (circular shape) and a plurality of teeth 23.

[0016]

The core back 22 is formed in an annular shape in a plane view in which the rotary electric machine 10 is viewed from the axial direction.

25 The plurality of teeth 23 protrude inward in the radial direction from the core

back 22 (toward the central axis O of the core back 22 along the radial direction). The plurality of teeth 23 is disposed at equal intervals in the circumferential direction. In the present embodiment, 24 teeth 23 are provided every 15 degrees of the central angle about the central axis O. The plurality of teeth 23 are formed in the same shape and the same size. A slot 24 is formed between the teeth 23 adjacent in the circumferential direction.

The winding is wound around the teeth 23. The winding may be wound in a concentric manner or may be wound in a distributed manner.

[0017]

As illustrated in FIG. 3, the rotor 30 is disposed inside the stator 20 (stator core 21) in the radial direction. The rotor 30 includes the rotor core 31 and a plurality of permanent magnets 32.

The rotor core 31 is formed in a cylindrical shape (circular shape) disposed coaxially with the stator 20. The rotary shaft 60 is disposed in the rotor core 31. The rotary shaft 60 is fixed to the rotor core 31 so as to rotate together with the rotor core 31.

The plurality of permanent magnets 32 is fixed to the rotor core 31. In the present embodiment, one set of two permanent magnets 32 forms one magnetic pole 33. The plurality of pairs of permanent magnets 32 are disposed at equal intervals in the circumferential direction. In the present embodiment, 8 sets of (16 in total) permanent magnets 32 are provided every 45 degrees of the central angle about the central axis O.

[0018]

The rotary electric machine 10 is an interior magnet motor. A plurality of through-holes 34 penetrating the rotor core 31 in the axial direction is formed in the rotor core 31. The plurality of through-holes 34 is provided corresponding to the plurality of permanent magnets 32. Each of the permanent magnets 32 is fixed to the rotor core 31 in a state of being disposed in the corresponding through-hole 34. Each of the permanent

magnets 32 can be fixed to the rotor core 31, for example, by bonding an outer surface of the permanent magnet 32 to an inner surface of the through-hole 34 with an adhesive.

[0019]

Note that a laminated core can be adopted as the stator core 21 and the rotor core 31. The laminated core is formed by laminating a plurality of electrical steel sheets. The laminated electrical steel sheets are fixed to each other by, for example, wedging, adhesion, welding, or the like.

Each of the electrical steel sheets forming the stator core 21 and the rotor core 31 is formed by, for example, punching an electrical steel sheet serving as a base metal. As the electrical steel sheet, a known electrical steel sheet can be used. A chemical composition of the electrical steel sheet is not particularly limited. In the present embodiment, a non-oriented electrical steel sheet is adopted as the electrical steel sheet. As the non-oriented electrical steel sheet, a non-oriented electrical steel strip of JIS C 2552: 2014 can be adopted. However, as the electrical steel sheet, a grain-oriented electrical steel sheet can be adopted instead of the non-oriented electrical steel sheet. As the grain-oriented electrical steel sheet, an oriented electrical steel strip of JIS C 2553: 2012 can be adopted.

[0020]

Insulating coatings are provided on both surfaces of the electrical steel sheet in order to improve workability of the electrical steel sheet and iron loss of the laminated core. As a substance constituting the insulating coating, for example, (1) an inorganic compound, (2) an organic resin, and (3) a mixture of an inorganic compound and an organic resin can be applied. Examples of the inorganic compound include (1) a complex of a dichromate and boric acid, and (2) a complex of a phosphate and silica. Examples of the organic resin include an epoxy-based resin, an acrylic resin, an acrylic

styrene-based resin, a polyester-based resin, a silicon-based resin, and a fluorine-based resin.

[0021]

Details of the rotor 30 will be described below.

5 As illustrated in FIG. 3, the permanent magnets 32 are embedded in the rotor core 31 and the two form a pair to constitute one magnetic pole 33 as described above. A plurality of pairs (8 pairs in the illustrated example) of permanent magnets 32 are disposed in the rotor core 31 in the circumferential direction. In the illustrated example, the permanent magnet 32 has a rectangular parallelepiped shape. The permanent magnet
10 32 has a rectangular shape in plane view.

[0022]

The pair of permanent magnets 32 is disposed in a V shape protruding inward in the radial direction in the plane view. The pair of permanent magnets 32 is disposed line-symmetrically with respect to a d axis A in the plane view. The d axis A passes through
15 the central axis O and the circumferential center of each magnetic pole 33 in the plane view. The through-holes 34 in which the pair of permanent magnets 32 are disposed are also disposed generally line-symmetrically with respect to the d axis A.

[0023]

The through-hole 34 is larger than the permanent magnet 32 on both sides: a q
20 axis B side and the d axis A side in the plane view. The q axis B passes through the central axis O and between two magnetic poles 33 adjacent in the circumferential direction in the plane view. The q axis B passes through a circumferential center between the two magnetic poles 33 in the plane view. The q axis B and the d axis A are magnetically and electrically orthogonal to each other. Portions of the through-hole 34
25 positioned on the q axis B side and the d axis A side with respect to the permanent

magnet 32 are flux barriers 35 and 36, respectively. In other words, the flux barriers 35 and 36 are provided at both ends of the permanent magnets 32 on the q axis B side and the d axis A side. The flux barriers 35 and 36 are magnetic voids penetrating the rotor core 31 in the axial direction. The flux barriers 35 and 36 reduce the magnet magnetic flux (hereinafter, also referred to as a reflux magnetic flux) from the permanent magnet 32 refluxing in the rotor 30, and change an inflow path of the magnet magnetic flux from the permanent magnet 32 to the stator 20. As a result, the magnet magnetic flux of the permanent magnet 32 (hereinafter, simply the magnet magnetic flux) is effectively transmitted to the stator 20, and high torque is output. It can also be said that the flux barriers 35 and 36 guide the magnet magnetic flux to the stator 20.

[0024]

The rotor 30 includes a first flux barrier 35 and a second flux barrier 36 as the flux barriers 35 and 36. The first flux barrier 35 and the second flux barrier 36 sandwich the permanent magnet 32 from both ends. This facilitates effective transmission of the magnet magnetic flux to the stator 20.

The first flux barrier 35 is positioned on the q axis B side closest to one permanent magnet 32. The first flux barriers 35 are positioned on both outer sides of the pair of permanent magnets 32 in the circumferential direction (rotation direction). The second flux barrier 36 is positioned on the d axis A side closest to one permanent magnet 32. It is positioned at the center in the circumferential direction (rotation direction) of the pair of permanent magnets 32.

[0025]

The first flux barrier 35 extends radially outward the rotor core 31 from the end surface on the q axis B side closest to one permanent magnet 32. The first flux barrier 35 includes a first space 37 and a second space 38. In the first space 37, the end surface on

the q axis B side closest to one permanent magnet 32 is exposed. The first space 37 extends to the q axis B side closest to one permanent magnet 32 in the plane view. The first space 37 has a triangular shape protruding toward the q axis B side in the plane view. The space width of the first space 37 in the radial direction decreases to the q axis B side closest to one permanent magnet 32. The second space 38 communicates with the first space 37. At least a part of the second space 38 is positioned radially outside the first space 37. In the plane view, the second space 38 has a rectangular shape. In the plane view, the area of the second space 38 is smaller than the area of the first space 37.

[0026]

A first bridge 39 is provided radially outside the first flux barrier 35. The first bridge 39 is a part of the rotor core 31. The first bridge 39 is a portion of the rotor core 31 that is positioned radially outside the first flux barrier 35. With the presence of the first bridge 39, centrifugal resistance of the rotor core 31 is improved as compared with the case where the first bridge 39 is absent. The first bridge 39 ensures dynamic strength on the outer periphery of the rotor core 31. When the radial width of the first bridge 39 is sufficiently narrow, the magnetic flux passing through the first bridge 39 is prevented by magnetic saturation, and the reflux of the magnet magnetic flux is prevented.

[0027]

The width (size in the radial direction) of the first bridge 39 is locally smaller than the width of both portions of the rotor core 31 adjacent to the first bridge 39 in the circumferential direction.

Note that the length (size in the circumferential direction) and width of the first bridge 39 are appropriately designed according to the rotation speed and the shape of the rotary electric machine 10. For example, the width of the first bridge 39 is smaller than the width of both portions of the rotor core 31 adjacent to the first bridge 39 in the

circumferential direction, but may not be locally smaller. For example, the width of the first bridge 39 may be continuously smaller than the width of both portions of the rotor core 31 adjacent to the first bridge 39 in the circumferential direction. In this case, for example, in the outer circumferential portion of the rotor core 31, a portion in which the radial size (width) is 1% or less of the outer diameter of the rotor core 31 may be the first bridge 39. In addition, the shape, the size, and the like of the first flux barrier 35 are not limited to the aspects described in the present embodiment.

[0028]

The second flux barrier 36 includes a first space 37 in which the end surface on the d axis A side closest to one permanent magnet 32 is exposed. The first space 37 extends to the d axis A side closest to one permanent magnet 32 in the plane view. A second bridge 40 is provided between the two second flux barriers 36 forming a pair in each magnetic pole 33. The second bridge 40 is longer in the radial direction than in the circumferential direction. The second bridge 40 causes magnetic flux saturation in the second bridge 40 and inhibits formation of a magnetic circuit. The second bridge 40 is positioned on the d axis A.

[0029]

Hereinafter, the front in the rotation direction (circumferential direction) of the rotary electric machine 10 is simply referred to as front F, and the rear in the rotation direction is simply referred to as rear R. Note that, in the case of the rotary electric machine 10 rotatable in both directions about the central axis O, the rotation direction means a rotation direction in which the rotary electric machine 10 mainly rotates. In addition, in the illustrated example, the counterclockwise direction when the paper surface is viewed is referred to as the front F, and the clockwise direction is referred to as the rear R.

[0030]

The pair of permanent magnets 32 includes a front magnet 32f and a rear magnet 32r. The front magnet 32f is positioned on the front F side with respect to the rear magnet 32r.

5 The two first bridges 39 included in one magnetic pole 33 include a front bridge 39f and a rear bridge 39r. The front bridge 39f is provided with respect to the front magnet 32f. The front bridge 39f is positioned on the front F side (q axis B side) and radially outside with respect to the front magnet 32f. The front bridge 39f is positioned radially outside the first flux barrier 35 located on the front F side among the pair of first
10 flux barriers 35. The rear bridge 39r is provided with respect to the rear magnet 32r. The rear bridge 39r is positioned on the rear R side (q axis B side) and radially outside with respect to the rear magnet 32r. The rear bridge 39r is positioned radially outside the first flux barrier 35 positioned on the rear R side among the pair of first flux barriers 35.

[0031]

15 A reference location with respect to the front bridge 39f is defined as a front reference location Pf, and a reference location with respect to the rear bridge 39r is defined as a rear reference location Pr as described below. The front reference location Pf is an intersection point of a front imaginary line L1 passing through the central axis O and a circumferential front end of the front magnet 32f on the front F side and the outer
20 circumferential surface of the rotor core 31 in the plane view. The rear reference location Pr is an intersection point of a rear imaginary line L2 passing through the central axis O and a circumferential rear end of the rear magnet 32r on the rear R side and the outer circumferential surface of the rotor core 31 in the plane view.

[0032]

25 Then, in the present embodiment, as illustrated in FIGS. 3 and 4, a front end

39r1 of the rear bridge 39r positioned on the most front F side is disposed at a position away from the rear reference location Pr toward the front F side by θ_f (radian) at the central angle about the central axis O. A rear end 39f1 of the front bridge 39f positioned on the most rear R side is disposed at a position away from the front reference location Pf toward the front F side by 0 (radian) or more and θ_f (radian) or less at the central angle about the central axis O.

However, θ_f satisfies Formulae (1) and (2) described below.

$$0 < \theta_f \leq (\theta_a/8) \dots (1)$$

$$\theta_a = 2\pi/(N_{\text{slot}}) \dots (2)$$

where N_{slot} in Formula (2) described above means the number of slots of the stator.

θ_f is preferably $(\theta_a/16) < \theta_f < (5\theta_a/48)$ (Formula (3)).

The rear end 39f1 of the front bridge 39f positioned on the most rear R side is preferably disposed at a position away from the front reference location Pf toward the front F side by 0 (radian) or more and $\theta_a/48$ (radian) or less at the central angle about the central axis O.

[0033]

Further, in the present embodiment, as illustrated in FIG. 5, the rear end 39f1 of the front bridge 39f is disposed at the front reference location Pf. As illustrated in FIG. 4, the front end 39r1 of the rear bridge 39r is disposed at a position away from the rear reference location Pr toward the front F side by $\theta_a/12$ (radian) at the central angle about the central axis O.

[0034]

Here, the rear end 39f1 of the front bridge 39f and the front end 39r1 of the rear bridge 39r are portions of the bridges 39 where magnetic saturation of the magnetic flux

generated by each set of permanent magnets 32 occurs. In other words, the rear end 39f1 of the front bridge 39f and the front end 39r1 of the rear bridge 39r are portions of the bridges 39 where the magnetic flux starts to cross from the rotor 30 to the stator 20. The rear end 39f1 of the front bridge 39f and the front end 39r1 of the rear bridge 39r are magnetic saturation start positions of each bridge 39. The magnetic saturation start position in the front bridge 39f is a circumferential end portion position on the rear R side of the magnetic saturation start position of the rear end 39f1. The magnetic saturation start position in the rear bridge 39r is a circumferential end portion position on the front F side of the magnetic saturation start position of the front end 39r1. The magnetic saturation start position is a position where the distance between the front bridge 39f and the rear bridge 39r and the outer circumferential surface of the rotor core 31 is the shortest. The magnetic saturation start position of the bridge 39 may be obtained as a position where the absolute value of the magnetic flux density obtained by, for example, electromagnetic field analysis exceeds the saturation magnetic flux density of a magnetic material used for the rotor core. Instead of the electromagnetic field analysis, an experiment using an actual object may be adopted. The magnetic saturation start position can be specified by any one or more methods described above.

The rear end 39f1 of the front bridge 39f and the front end 39r1 of the rear bridge 39r is a boundary of the first bridge 39 with respect to a portion other than the first bridge 39. The rear end 39f1 of the front bridge 39f and the front end 39r1 of the rear bridge 39r are defined as regions connecting the first flux barrier 35 of the rotor core 31 and the outer circumferential surface of the rotor core 31 with the shortest distance in the radial direction. The front end 39r1 of the rear bridge 39r and the rear end 39f1 of the front bridge 39f are partial regions on an imaginary line passing through the first flux barrier 35 and the central axis O.

FIG. 11 illustrates an image in which a magnetic flux flows in the rotary electric machine according to the present embodiment. Arrows A1 and A2 in FIG. 11 mean a flow of magnetic flux. The arrow A1 indicates a rough flow of the magnetic flux. The arrow A2 indicates a magnetic flux density vector at each position. As illustrated in FIG. 11, in the front bridge 39f, the magnetic flux passes through the stator 20 at the rear end 39f1 of the front bridge 39f. In the rear bridge 39r, the amount of magnetic flux entering the magnetic pole 33 side changes depending on the position of the front end 39r1 of the rear bridge 39r.

[0035]

For example, when the width (size in the radial direction) at the end on the rear R side in the portion (hereinafter, referred to as a first portion) of the rotor core 31 radially sandwiched between the first flux barrier 35 on the front F side and the outer circumferential surface of the rotor core 31 is sufficiently narrow, the rear end 39f1 of the front bridge 39f can be an end on the rear R side. In this case, the first portion becomes the front bridge 39f over the total length (length in the circumferential direction) of the first flux barrier 35. In this case, on the front F side of the rear end 39f1 of the front bridge 39f, the width of the front bridge 39f may be narrower or wider than the rear end 39f1. In other words, when the rear end 39f1 of the front bridge 39f is the magnetic saturation start position, the portion of the front bridge 39f positioned at the front with respect to the rear end 39f1 may be larger or smaller than the rear end 39f1 in the radial direction.

In addition, when the width of the end on the front F side in the portion (hereinafter, referred to as a second portion) of the rotor core 31 radially sandwiched between the first flux barrier 35 on the rear R side and the outer circumferential surface of the rotor core 31 is sufficiently narrow, the front end 39r1 of the rear bridge 39r can be

an end on the front F end. In this case, the second portion becomes the rear bridge 39r over the total length (length in the circumferential direction) of the first flux barrier 35. In this case, on the rear R side of the front end 39r1 of the rear bridge 39r, the width of the rear bridge 39r may be narrower or wider than the front end 39r1.

5 [0036]

Further, for example, when the width of the end of the first portion on the rear R side is not sufficiently narrow, the rear end 39f1 of the front bridge 39f can be a region positioned on the most rear R side within the region where the width of the first portion is sufficiently narrow. In this case, a part of the first portion serves as the front bridge 39f, and the rear end 39f1 of the front bridge 39f is positioned on the front F side with respect to the end of the first portion on the rear R side in the circumferential direction.

In addition, when the width of the end of the second portion on the front F side is not sufficiently narrow, the front end 39r1 of the rear bridge 39r can be a region positioned on the most front F side within the region where the width of the second portion is sufficiently narrow. In this case, a part of the second portion serves as the front bridge 39f, and the front end 39r1 of the rear bridge 39r is positioned on the rear R side with respect to the end of the second portion on the front F side in the circumferential direction.

[0037]

20 Note that, in any of the above cases, the fact that the widths of the first portion and the second portion are sufficiently narrow may mean that, for example, the width is 1% or less of the outer diameter of the rotor core 31. In addition, the fact that the widths of the first portion and the second portion are sufficiently narrow may mean that the width is, for example, 0.3 mm or less. In addition, in order to specify the rear end 39f1 of the front bridge 39f and the front end 39r1 of the rear bridge 39r, the rotary electric

25

machine 10 may be reproduced on software and electromagnetic field analysis may be performed.

[0038]

Here, the central angle with respect to the rear end 39f1 of the front bridge 39f
5 and the front reference location Pf is the central angle about the central axis O with
respect to an imaginary line L1a related to the front bridge 39f and the front imaginary
line L1. The imaginary line L1a is an imaginary line passing through the rear end 39f1
of the front bridge 39f and the central axis O. Note that the fact that the central angle
with respect to the rear end 39f1 of the front bridge 39f and the front reference location
10 Pf is 0 (radian), in other words, the rear end 39f1 of the front bridge 39f is disposed at the
front reference location Pf means that the imaginary line L1a and the front imaginary line
L1 coincide with each other. Note that when the angle between the front imaginary line
L1 and the imaginary line L1a is θ_s , $0 \leq \theta_s \leq \theta_f$ holds, and in the present embodiment, θ_s
= 0 holds.

15 [0039]

In addition, the central angle with respect to the front end 39r1 of the rear bridge
39r and the rear reference location Pr is the central angle about the central axis O with
respect to an imaginary line L2a related to the rear bridge 39r and the rear imaginary line
L2. The imaginary line L2a is an imaginary line passing through the front end 39r1 of
20 the rear bridge 39r and the central axis O. Note that when the angle between the rear
imaginary line L2 and the imaginary line L2a is θ_t , $0 < \theta_t \leq (\theta_a/8)$ holds, and in the
present embodiment, $\theta_t = (\theta_a/12)$ holds.

[0040]

The inventor of the present application has found that the circumferential
25 position of the rear end 39f1 of the front bridge 39f and the circumferential position of

the front end 39r1 of the rear bridge 39r, in other words, the start position of the first bridge 39 affects the size of the optimum advance angle.

[0041]

This finding was obtained through the process described below.

5 The inventor of the present application analyzed shape optimization of the rotor core 31. This analysis is based on the contents described in Japanese Unexamined Patent Application, First Publication No. 2021-114099. The inventor of the present application performed the analysis a plurality of times on the premise of a plurality of different advance angles. It can be said that the shape of the rotor core 31 as a result of each
10 analysis is an optimum shape according to the advance angles serving as the premise.

[0042]

 The inventor of the present application confirmed the result of each analysis and found that the position of the first flux barrier 35 (flux barriers 35 and 36 positioned on the q axis B side with respect to the permanent magnet 32) moves in the circumferential
15 direction according to the advance angles serving as the premise. Conversely, when the first flux barrier 35 is moved in the circumferential direction, the optimum advance angle changes.

[0043]

 Therefore, the inventor of the present application newly performed the analysis
20 described below. In this analysis, the circumferential position of the first bridge 39 was changed from position 0 to position 3 illustrated in FIGS. 6 to 9, and then the optimum advance angle in each shape was obtained.

[0044]

 Note that position 0 is a rotor 30A illustrated in FIG. 6, position 1 is a rotor 30B
25 illustrated in FIG. 7, position 2 is a rotor 30C illustrated in FIG. 8, and position 3 is a

rotor 30D illustrated in FIG. 9. At position 0, the rear end 39f1 of the front bridge 39f is positioned at the front reference location Pf, and the front end 39r1 of the rear bridge 39r is positioned at the rear reference location Pr. The circumferential position of the rear end 39f1 of the front bridge 39f and the circumferential position of the front end 39r1 of the rear bridge 39r are positioned on the front F side by 0.65 degrees (corresponding to an electrical angle of 2.5 degrees in a four-pole motor as in the present embodiment) from position 0 toward position 3 for both the front bridge 39f and the rear bridge 39r. In FIG. 6 and the subsequent drawings, the description of the imaginary lines L1a and L2a are omitted.

Table 1 below indicate the analysis results.

[0045]

[Table 1]

	Position 0	Position 1	Position 2	Position 3
Optimum advance angle	50 to 52.5°	52.5 to 55°	55 to 57.5°	57.5 to 60°

[0046]

As in Table 1, it has been confirmed that the optimum advance angle increases by moving the circumferential position of the rear end 39f1 of the front bridge 39f and the circumferential position of the front end 39r1 of the rear bridge 39r to the front F side. Note that the optimum advance angle increases by 0.25 degrees from position 0 toward position 3. This angle coincides with the electrical angle. Thus, it has been confirmed that the movement angle of the position of the first bridge 39 corresponds to the change in the optimum advance angle.

[0047]

Therefore, the inventor of the present application intensively studied the

circumferential position of the rear end 39f1 of the front bridge 39f and the circumferential position of the front end 39r1 of the rear bridge 39r in units of θ_a (radian) at the central angle corresponding to the pitch of the teeth 23 of the stator 20, and found that by setting as described above, high torque can be output while utilizing the voltage reduction effect at the increased advance angle.

[0048]

This finding was obtained through the process described below.

The inventor of the present application conducted a new analysis. A target rotary electric machine 10 is a rotary electric machine 10 including rotors 30, 30A, and 30E illustrated in FIGS. 3, 6, and 10. In the rotary electric machine 10, since the number of slots is 24 as described above, $\theta_a = 15$ degrees. In the rotary electric machine 10, the analysis was performed on the premise of the shape in which the position of the first bridge 39 was moved to the rotation front F side by 0.625 degrees (that is, $(\theta_a/24)$ degrees), and the value of torque/voltage was evaluated. Note that, in the rotor 30 illustrated in FIG. 3, the rear end 39f1 of the front bridge 39f is positioned at the front reference location Pf, and the front end 39r1 of the rear bridge 39r is moved to the front F side by 1.25° with respect to the rear reference location Pr. In the rotor 30E illustrated in FIG. 10, the rear end 39f1 of the front bridge 39f is moved to the front F side by 0.625° with respect to the front reference location Pf, and the front end 39r1 of the rear bridge 39r is moved to the front F side by 0.625° with respect to the rear reference location Pr.

[0049]

The analysis conditions are as indicated in Table 2, and the absolute maximum value was used as the voltage value. The analysis results are as indicated in Table 3. Note that, in Table 3, the results of both the front bridge 39f and the rear bridge 39r are normalized with the movement angle of 0 degrees as a reference of 100.

[0050]

[Table 2]

Current	20 A _{peak}
Advance angle	Torque in each shape / Advance angle at which voltage is maximized
Frequency	50 Hz
Magnet residual magnetic flux density	0.4 T
Rotor diameter	27 mm

[0051]

5 [Table 3]

Torque [Nm] /Voltage [V _{peak}]		Rotation front bridge				
		0°	+0.625°	+1.25°	+1.875°	+2.5°
Rotation rear bridge	0°	100	98.1	97.3	96.5	–
	+0.625°	103.0	100.1	99.4	98.7	–
	+1.25°	105.7	104.6	101.9	100.0	–
	+1.875°	101.3	102.5	102.1	101.2	99.9
	+2.5°	99.8	100.0	99.8	99.7	–

[0052]

As indicated by the thick frame (within hatching) in Table 3, it has been confirmed that this value is larger than the reference in a range in which the movement angle of the rear bridge 39r is larger than 0 and equal to or smaller than 1.875 degrees (that is, $(\theta_a/8)$ degrees) and the movement angle of the front bridge 39f does not exceed the movement angle of the rear bridge 39r. In addition, in a case where the movement angle of the rear bridge 39r is 1.25 degrees (that is, $(\theta_a/12)$ degrees) and the movement angle of the front bridge 39f is 0 degrees, it has been confirmed that this value is the

maximum.

Note that the movement angle was measured by a simulation model.

Specifically, the measurement was performed from the coordinates of node points included in a bridge portion on the simulation model.

5 [0053]

Note that magnetic saturation occurs at the start position of the first bridge 39 in the process of transmitting the magnetic flux generated in the magnetic pole 33 constituted by the pair of permanent magnets 32 in the rotor core 31. Then, the magnetic flux flows from the inside to the outside of the rotor core 31 and is transmitted to the
10 teeth 23 of the stator 20. Therefore, the start position of the first bridge 39 is a starting point at which the magnetic flux is transmitted to the stator 20. The fact that the start position of the first bridge 39 is the starting point in this manner is considered to be related to the fact that the start position of the first bridge 39 affects the size of the optimum advance angle.

15 [0054]

Note that the technical scope of the present invention is not limited only to the above-described embodiment, and various modification can be made without departing from the gist of the present invention.

[0055]

20 The shape of the stator 20 is not limited only to the forms described in the embodiment. Specifically, the dimensions of the outer diameter and the inner diameter of the stator core 21, the laminating thickness, the number of slots, a dimensional proportion between a circumferential direction and a radial direction of the teeth 23, a dimensional proportion between the tooth 23 and the core back 22 in the radial direction, and the like
25 can be arbitrarily designed according to desired characteristics of the rotary electric

machine 10.

[0056]

The shape of the rotor 30 is not limited only to the forms described in the embodiment. Specifically, the dimensions of the outer diameter and the inner diameter of the rotor core 31, the laminating thickness, the number of poles, and the like can be
5 arbitrarily designed according to desired characteristics of the rotary electric machine 10.

[0057]

In the above embodiment, both the stator core 21 and the rotor core 31 are laminated cores, but may not be laminated cores.

10 There may be no second flux barrier 36.

[0058]

In the above embodiment, one magnetic pole 33 includes two permanent magnets 32. However, the present invention is not limited thereto. For example, one magnetic pole 33 may include one permanent magnet 32, three permanent magnets 32, or
15 four or more permanent magnets 32. As one set of permanent magnets 32, another form including one or more permanent magnets 32 is appropriately adopted.

For example, when one set of permanent magnets 32 is one permanent magnet 32, the one permanent magnet 32 may have a rectangular shape that is long in a direction orthogonal to the d axis A in the plane view.

20 For example, in a case where one set of permanent magnets 32 is three permanent magnets 32 and the three permanent magnets 32 are arranged in the circumferential direction, the disposition described below may be adopted. In this case, the permanent magnet 32 positioned at the center in the circumferential direction may have a rectangular shape that is long in the direction orthogonal to the d axis A in the
25 plane view. Further, in this case, the two permanent magnets 32 located on both sides in

the circumferential direction may extend radially outward from the d axis A side toward the q axis B side in the plane view.

[0059]

Additionally, it is possible to appropriately replace the constituent elements in
5 the embodiment with well-known constituent elements without departing from the gist of the present invention, and the above-described modification examples may be appropriately combined with each other.

[Field of Industrial Application]

[0060]

10 According to the present invention, it is possible to improve the torque with respect to the voltage. Therefore, industrial applicability is large.

[What is claimed is]

[Claim 1] A rotary electric machine comprising:

a stator having an annular shape; and

a rotor that is disposed in the stator,

5 wherein

the rotor includes:

a rotor core; and

a plurality of sets of permanent magnets embedded in the rotor core, each set of

the permanent magnets constituting one magnetic pole, the plurality of sets of the

10 permanent magnets disposed in the rotor core in a circumferential direction of the rotor core,

the rotor core includes:

a first flux barrier provided on both sides in a rotation direction of the rotor with respect to each set of the permanent magnets; and

15 a first bridge provided outside the rotor core in a radial direction with respect to the first flux barrier, and

the first bridge includes:

a front bridge provided at a front in the rotation direction of the rotor; and

a rear bridge provided at a rear in the rotation direction of the rotor, and

20 wherein when a front reference location that is a reference location of the front

bridge is an intersection point of a front imaginary line passing through a center axis of

the rotor core and a front end of each set of the permanent magnets and an outer

circumferential surface of the rotor core in a plane view in which the rotor is viewed

from an axial direction, and a rear reference location that is a reference location of the

25 rear bridge is an intersection point of a rear imaginary line passing through the center

axis of the rotor core and a rear end of each set of the permanent magnets and the outer circumferential surface of the rotor core in the plane view,

in at least one set of the permanent magnets among the plurality of sets of the permanent magnets,

- 5 a front end of the rear bridge is disposed at a position away from the rear reference location to the front by θ_f (radian) at a central angle about the center axis, and
- a rear end of the front bridge is disposed at a position away from the front reference location to the front by 0 (radian) or more and θ_f (radian) or less at the central angle about the center axis,

- 10 where, θ_f satisfies Formulae (1) and (2) described below.

$$0 < \theta_f \leq (\theta_a/8) \dots (1)$$

$$\theta_a = 2\pi/(N_{\text{slot}}) \dots (2)$$

where N_{slot} in Formula (2) described above means a number of slots of the stator.

- 15 [Claim 2] The rotary electric machine according to claim 1, wherein

in the at least one of the plurality of sets of the permanent magnets,

the rear end of the front bridge is disposed at the front reference location, and

the front end of the rear bridge is disposed at a position away from the rear reference location to the front by $\theta_a/12$ (radian) at the central angle about the center axis.

- 20 [Claim 3] The rotary electric machine according to claim 1 or 2, wherein

two permanent magnets form a set to constitute one magnetic pole,

each set of the permanent magnets includes a front magnet positioned at the front and a rear magnet positioned at the rear, the front magnet and the rear magnet are disposed in a V shape protruding inward in the radial direction in the plane view,

- 25 the front bridge is provided in front of the front magnet,

the rear bridge is provided in the rear of the rear magnet, and

in the plane view, the front imaginary line passes through the center axis and a front end of the front magnet, and the rear imaginary line passes through the center axis and a rear end of the rear magnet.
