

DESCRIPTION

NOVEL TETRAHYDROISOQUINOLINE DERIVATIVE

Technical Field

The present invention relates to a compound or a pharmacologically acceptable salt thereof having a particular chemical structure having an excellent acyl-coenzyme A: diacylglycerol acyltransferase (Acyl-CoA: diacylglycerol acyltransferase, hereinafter, also referred to as DGAT) inhibitory effect and an excellent feeding suppressant effect.

Background Art

Adiposity is a condition of having a significantly greater body weight than normal as a result of accumulation of neutral fats (triacylglycerol or triglyceride, hereinafter also referred to as TG) in fat cells due to continuous excess energy intake compared to energy consumption (Non-Patent Document 1). Adiposity leads to life-style related disease (e.g., hyperlipidemia, hypertriglyceridemia, diabetes, hypertension, and arteriosclerosis), cerebrovascular disorder, coronary artery disease, respiratory abnormality, lower back pain, knee osteoarthritis, gout, cholelithiasis, and so on. Adiposity with a complication of these diseases or

adiposity which may later lead to such a complication is defined as obesity and treated as a disease.

Moreover, in recent years, obesity has been shown to be one of the major causes of a life-style related disease called metabolic syndrome (Non-Patent Document 2). It has been reported that in individuals with obesity, fatty acids and factors such as TNF- α are released from accumulated visceral fats, and induce insulin resistance in skeletal muscles, the liver, and fat tissue while facilitating the synthesis of neutral fats in the liver, resulting in hyperlipidemia. Furthermore, an increase in serum insulin concentration induced by the insulin resistance causes impaired glucose tolerance and diabetes and increases peripheral vascular resistance via increased renal reabsorption of Na ions and activation of sympathetic nerves, causing hypertension. Hyperlipidemia, diabetes, and hypertension caused by obesity are also thought to trigger angiopathy such as cerebrovascular disorder or coronary artery disease caused by arteriosclerosis, resulting in severe, life-threatening clinical conditions.

Currently, drug therapy has been practiced on obesity based on the provisions of each country, and centrally acting anorectics such as mazindol (Non-Patent Document 3) and sibutramine (Non-Patent Document 4) and lipid absorption inhibitors such as the pancreatic lipase inhibitor orlistat are prescribed mainly for the purpose

of controlling calorie intake. These drugs offer low satisfaction with treatment, although achieving some therapeutic effects. The centrally acting anorectics have adverse effects such as dry mouth, constipation, gastric discomfort, and in some cases, auditory hallucination and visual hallucination. Orlistat (Non-Patent Document 5) may cause adverse effects in the gastrointestinal tract, such as diarrhea, incontinence, steatorrhea, and flatus. Accordingly, there is a need for the development of more potent drugs with fewer adverse effects. Under such circumstances, active research and development has been conducted with the aim of developing novel anti-obesity drugs, most of which are anorectics.

Animals and plants store lipids as insoluble TG and produce energy by catabolizing TG according to need. TG taken from food is hydrolyzed into free fatty acid and monoacylglycerol in the lumen of the small intestine by the action of bile acid and pancreatic lipase. Micelles composed of free fatty acid, monoacylglycerol, and bile acid are absorbed into small intestinal epithelial cells in which TG is then re-synthesized in the endoplasmic reticulum by the action of acyl-coenzyme A synthetase (hereinafter, referred to as ACS), acyl-coenzyme A: monoacylglycerol acyltransferase, and DGAT. TG is combined with phospholipid, cholesterol, and apolipoprotein and secreted in the form of chylomicron

into the lymph vessels in the stomach and intestine. TG is then secreted into the blood through the lymphatic trunk and transferred to the periphery for use. On the other hand, TG is also synthesized in fat tissue from glycerol 3-phosphate and free fatty acid by the action of ACS, glycerol 3-phosphate acyltransferase, lysophosphatidic acid acyltransferase, and DGAT (Non-Patent Document 6). TG taken excessively is thus accumulated in fat tissue, resulting in obesity.

DGAT, an intracellular enzyme found in the endoplasmic reticulum, catalyzes the most important reaction in the final step in the pathway of TG synthesis, i.e., the reaction of transferring acyl groups of acyl-coenzyme A to the 3 position of 1,2-diacylglycerol (Non-Patent Documents 7 to 9). It has been reported that DGAT has two isozymes DGAT1 (Non-Patent Document 10) and DGAT2 (Non-Patent Document 11). Since DGAT1 and DGAT2 are highly expressed in the small intestine and fat tissue and in the liver and fat tissue, respectively, it is believed that DGAT1 is involved mainly in fat absorption from the small intestine and fat accumulation in fat tissue and DGAT2 is involved mainly in TG synthesis or VLDL (very low density lipoprotein) secretion in the liver and fat accumulation in fat tissue. Although the difference between the roles of DGAT1 and DGAT2 has not yet been fully elucidated, the association of DGAT with obesity, lipid metabolism, glucose metabolism, and the

like has been suggested (Non-Patent Document 12). DGAT is a key enzyme of TG synthesis in gastrointestinal epithelial cells and fat tissue. Drugs which inhibit DGAT suppress the TG synthesis and thus suppress fat absorption in the gastrointestinal tract and fat accumulation in fat tissue. Accordingly, such drugs are expected to be useful as therapeutic or preventive agents for, for example, adiposity, obesity, hyperlipidemia, hypertriglyceridemia, lipidoses, insulin resistance syndrome, diabetes, nonalcoholic steatohepatitis, or hyperlipidemia, hypertriglyceridemia, lipidoses, insulin resistance syndrome, diabetes, nonalcoholic steatohepatitis, hypertension, arteriosclerosis, cerebrovascular disorder, or coronary artery disease caused by obesity (Non-Patent Documents 13 to 17).

Anorectics directly or indirectly regulate the system of appetite control, and their mechanisms of action are broadly classified into central and peripheral actions. The centrally acting anorectics directly suppress appetite through their action on the hypothalamic neuronal system containing the feeding and satiety centers or on the monoaminergic neuronal system in the brain regulating this hypothalamic neuronal system. On the other hand, the peripherally acting anorectics indirectly suppress appetite through their action on the mechanism of detecting and transmitting information on

nutrition intake from diets or accumulation of excess energy.

In recent years, the mechanism has been increasingly evident, in which, for example, gastrointestinal hormone (CCK, GLP-1, PYY, etc.) (Non-Patent Document 18) secreted in close relation to the digestion and absorption of food, or leptin (Non-Patent Document 19) secreted from fat cells in response to the amount of energy accumulated (amount of fats) conveys hormonal or neuronal signals regulating appetites from the periphery to the central nervous system. Novel anorectics associated with these peripheral signals are expected to serve as more effective anti-obesity drugs with fewer adverse reactions.

Patent Document 1 discloses compounds structurally similar to compounds of the present invention. This document describes compounds comprising two substituted phenyl groups bound via urea and amide bonds or via urea and ester bonds with a tetrahydroisoquinoline ring, and use thereof as a DGAT inhibitor. Moreover, Patent Document 2 describes use of these compounds as a feeding suppressant. However, these patent documents merely disclose compounds wherein a nitrogen atom on the tetrahydroisoquinoline ring is substituted by a substituted phenyl group via an amide or ester bond. On the other hand, in the compounds of the present invention, a nitrogen atom on a tetrahydroisoquinoline ring is

substituted by a substituted cycloalkyl or cycloalkenyl group via an ester bond or the like.

In addition, some compounds having a DGAT inhibitory effect are known. However, all differ from the compounds of the present invention in their structures (e.g., Patent Documents 3, 4, and 5 and Non-Patent Documents 20 to 24). Also, some compounds having a feeding suppressant effect are known. However, all differ from the compounds of the present invention in their structures (see e.g., Patent Documents 6 and 7).

The residue was diluted with ethyl acetate, washed with water and saturated brine, then dried over sodium sulfate, and then concentrated. The residue was purified by column chromatography (dichloromethane/methanol) to obtain ester (404 mg, 86%) as an orange oil. To a mixture of this ester (404 mg) and methanol (6 mL), 1 N hydrochloric acid (1.8 mL) was added. The reaction mixture was stirred overnight and concentrated. and then dried under reduced pressure to obtain the title compound (193 mg, 51%) as a yellow solid.

(Test Example 1)

(1) Preparation of DGAT1 enzyme

DGAT1 enzyme was prepared and stored according to the method described in US2007/0249620.

(2) DGAT1 inhibitory activity test

A reaction solution having the following composition was incubated at room temperature (23°C) for 30 minutes: 175 mM Tris-HCl (pH 8.0), 8 mM MgCl₂, 1 mg/ml BSA, 0.3 mM 1,2-dioleoyl-sn-glycerol (10-fold concentration of EtOH solution, 10% added), 10 μ M [¹⁴C]-oleoyl-CoA (approximately 50 mCi/mmol), 0.5% triton X-100, the DGAT1 enzyme (10 μ g) obtained in Test Example 1(1), and a test compound or vehicle (DMSO/MeOH, 7:3 solution, 5% added), 50 μ l in total. A reaction stop solution (70 μ l) consisting of isopropanol/1-heptane/water (80:20:2, v/v/v) was added to the reaction solution and stirred. Subsequently, water (30 μ l) and 1-heptane (100 μ l) were added thereto and stirred. The 1-heptane layer (50 μ l) was spotted onto a TLC plate and developed with a developing solvent consisting of 1-hexane/diethyl ether/acetic acid (85:15:1, v/v/v). The radioactivity of

the triglyceride fraction was quantified using BAS2000 Bio Image Analyzer (FUJIFILM) and compared with the control. The inhibitory activity of the test compound was calculated according to the formula shown below. In this context, the radioactivity at no reaction (0 minute incubation) was used as background.

$$\text{Inhibitory Rate} = 100 - \frac{[(\text{Radioactivity of sample supplemented with test compound}) - (\text{Background})]}{[(\text{Radioactivity of control}) - (\text{Background})]} \times 100$$

The compounds of Examples 2-3, 5-45, 47-62, 64-80, 82-86, 90-95, 97-107, and 108 exhibited a 50% or higher inhibitory rate at the test compound concentration of 0.05 µg/ml.

In this context, the DGAT inhibitory activity test is not limited to the method described above. For example, microsomes prepared from the small intestine, fat tissue, or liver of animals (e.g., rats or mice) may be used as the DGAT enzyme. Moreover, microsomes prepared from cultured cells (3T3-L1 fat cells, primarily cultured fat cells, Caco2 cells, HepG2 cells, etc.) or cultured cells highly expressing DGAT can also be used as the DGAT enzyme. Furthermore, flush plates (PerkinElmer) that require no extraction procedure can be used for efficiently evaluating a large number of test compounds in a short time.

As is evident from these results, compounds of the present invention have excellent DGAT1 inhibitory bioactivity.

(Test Example 2)

The DGAT1 enzyme is important for the digestion and absorption of triglycerides, and the inhibition of DGAT1 in the small intestine suppresses the absorption of triglycerides. The in vivo activity of its DGAT1 inhibitory effect was evaluated with the suppressed absorption of triglycerides after fat loading as an index. Male C57BL/6N mice (7-12 weeks old, body weight: 17-25 g, Charles River Laboratories Japan Inc.) fasted overnight were assigned to Vehicle group 1, Vehicle group 2, and each test compound group, to which a vehicle (0.5% methylcellulose) or each test compound (1 to 10 mg/kg) suspended in vehicle was orally administered (5 mL/kg). After a given time, a lipoprotein lipase inhibitor (Pluronic-F127: Sigma-Aldrich Corp., 1 g/kg, 20% by weight dissolved in saline) was intraperitoneally administered (5 mL/kg) to each group. Immediately thereafter, distilled water for the Vehicle group 1 or a 20% fat-containing emulsion (Intralipid 20%: TERUMO CORP., Japan) for the Vehicle group 2 and the compound groups were orally administered thereto (0.2 mL/mouse). After a given time of 1 to 4 hours after administration, blood was collected from the tail vein or the right

ventricle, and plasma was immediately separated and collected. Then, the triglyceride concentration in plasma was measured using a commercially available kit (Triglyceride E-Test Wako: Wako Pure Chemical Industries, Ltd.). In this method, the administration of the lipoprotein lipase inhibitor suppresses the hydrolysis of triglycerides in the blood such that the triglycerides are accumulated in the blood. These triglycerides are derived from two origins: exogenous triglycerides absorbed in the gastrointestinal tract and endogenous triglycerides released from the liver. The triglyceride absorption suppressive activity of each test compound was calculated based on the equation shown below by removing the influence of the endogenous triglycerides. In this context, each test compound was separately confirmed to have no influence on the concentration of the endogenous triglycerides.

$$\text{Triglyceride absorption suppressive activity (\%)} = 100 - \frac{(\text{Triglyceride concentration of each test compound group}) - (\text{Triglyceride concentration of Vehicle group 1})}{(\text{Triglyceride concentration of Vehicle group 2}) - (\text{Triglyceride concentration of Vehicle group 1})} \times 100$$

The compounds of Examples 2, 5, 7, 8, 10, 11, 12, 13, 15, 16, 17, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 41, 43-62, 64, 66-78, 80-86, 90-92, 95, 97, 99-105, 107, and 108 exhibited 60% or higher triglyceride

absorption suppressive activity at a dose of 10 mg/kg or lower.

As is evident from these results, compounds of the present invention have excellent triglyceride absorption suppressive activity.

(Test Example 3)

Male C57BL/6N mice (7-12 weeks old, body weight: 17-25 g, Charles River Laboratories Japan Inc.) were individually housed and fed on a high-fat diet (fat content: 45 kcal%: Research Diets, Inc. D12451) for 1 week or longer for acclimatization. Based on the food intake during the period, the animals were equally assigned to experimental groups and fasted overnight. Then, a vehicle (0.5% methylcellulose) or each test compound (1 to 10 mg/kg) suspended in vehicle was orally administered (10 mL/kg) to each group. 30 minutes after administration, the animals were fed on a high-fat diet, and the food intake was measured 6 hours after initiation of feeding. The feeding suppressant activity of each test compound was calculated based on the equation shown below.

$$\text{Feeding suppressant activity (\%)} = \frac{[(\text{Food intake of Vehicle group}) - (\text{Food intake of each test compound group})]}{[(\text{Food intake of Vehicle group})]} \times 100$$

The compounds of Examples 2 and 20 exhibited 25% or higher feeding suppressant activity at a dose of 10 mg/kg or lower.

As is evident from these results, compounds of the present invention have an excellent feeding suppressant effect.
