

HEMOSTATIC TEXTILE

BACKGROUND OF THE INVENTION

1. Field of the Invention

5 The present invention is directed to textiles, such as bandages, sutures, or fabrics, and more particularly to hemostatic textiles that include agents that can control bleeding rapidly and can be stored for long periods of time.

2. Description of the Related Art

10 Despite considerable progress in understanding pathophysiological processes involved in surface (topical) hemostasis, there remains a considerable unmet need for materials that can be applied to sites of hemorrhage to staunch bleeding. Traumatic injury is the leading cause of death for individuals under 44 years of age (Bozeman, W. Shock, Hemorrhage (2001)). Approximately half of the 100,000 deaths annually in the United
15 States per year from traumatic injury, or 50,000 cases, are from exsanguinations, (Peng, R., Chang, C., Gilmore, D. & Bongard, F. *Am Surg* Vol. 64 950-4 (1998)) and about the same number of hemorrhaging patients survive after massive red blood cell transfusion (Vaslef, S., Knudsen, N., Neligan, P., and Sebastian, M. *J. Trauma-Inj. Inf. Crit. Care* Vol. 53 291-296 (2002)). Thus, approximately 100,000 patients are in critical need of hemorrhage
20 control in the US each year. The situation is equally critical in combat casualty care; in a recent review of military casualties (Burlingame, B. DOD's experiences in Afghanistan Advanced Technological Applications for Combat Casualty Care 2002 Conference in www.usaccc.org (2002)), the control of non-compressible bleeding was identified as the single most important unmet need in military emergency medicine. The standard of care
25 is frequently the application of a tourniquet to control "compressible" bleeding and then gauze to control the residual "noncompressible" bleeding. However, continued blood loss through gauze is a major contributor to morbidity and mortality.

 The prior art is replete with patents directed to various forms of bandages. For example, U.S. Patent No. 3,419,006 to King discloses a sterile transparent dressing for a
30 wound and made from a hydrophilic polymeric gel of an insoluble polymer, and U.S. Patent No. 4,323,061 to Usukura discloses a rigid bandage made from glass fibers and non-glass fibers. In addition, various methods have been attempted to quickly arrest bleeding in an injured person. Several of these methods include articles such as bandages

supplemented with substances that chemically accelerate the body's natural clotting processes. Examples of such articles include the following:

U.S. Patent No. 3,328,259 to Anderson discloses a bandage or wound dressing that incorporates polymers such as sodium carboxymethyl cellulose, hydroxyethyl cellulose,
5 polyoxyethylene, polyvinylpyrrolidone, and the like.

U.S. Patent No. 4,192,299 to Sabatano discloses a bandage that includes a packet containing an antiseptic substance.

U.S. Patent No. 4,390,519 to Sawyer discloses a bandage in the form of a sponge and containing collagen or a collagen-like substance.

10 U.S. Patent No. 4,453,939 to Zimmerman et al. discloses a composition useful as a wound dressing and made from a combination of collagen, fibrinogen and thrombin.

U.S. Patent No. 4,606,337 to Zimmerman et al. discloses a resorptive sheet for closing and treating wounds, and composed of a glycoprotein matrix that contains fibrinogen and thrombin.

15 U.S. Patent No. 4,616,644 to Saferstein et al. discloses an adhesive bandage that includes high molecular weight polyethylene oxide as a hemostatic agent.

U.S. Patent No. 5,800,372 to Bell et al. discloses a dressing made from an absorbent polymer and includes microfibrillar collagen.

20 U.S. Patent No. 5,902,608 to Read et al. discloses surgical aids such as bandages, gauzes, sutures, and the like, that contain fixed-dried blood cells that express platelet-derived growth factors.

U.S. Patent No. 6,638,296 to Levinson discloses a bandage that includes a pad containing glucosamine or a glucosamine derivative.

25 U.S. Patent No. 6,762,336 and International Patent Application Publication No. WO/99/59647 to MacPhee et al. discloses a multilayer bandage that includes a thrombin layer sandwiched between two fibrinogen layers.

U.S. Patent No. 6,897,348 to Malik discloses an adhesive bandage that contains an antimicrobial agent and a hemostatic agent (e.g., chitosan, niacinamide, or ascorbic acid), or a single wound-healing agent that contains both antimicrobial and hemostatic activities
30 (e.g., chitosan niacinamide ascorbate salt).

U.S. Patent No. 6,891,077 to Rothwell et al. discloses fibrinogen bandages that include a procoagulant such as propyl gallate, gallic acid, or a derivative thereof. Optional ingredients such as thrombin or an antimicrobial agent may also be included.

In yet another aspect, the present invention is directed to a hemostatic textile, comprising: a material comprising a combination of about 65% by weight glass fibers and about 35% by weight raw or regenerated bamboo fibers; and from about 0.1 to about 5% by weight of thrombin or a fraction comprising thrombin based on the total weight of the textile; the hemostatic textile capable of activating hemostatic systems in the body when applied to a wound.

In yet another aspect, the present invention is directed to a hemostatic textile, comprising: a material comprising glass fibers and one or more secondary fibers selected from the group consisting of silk fibers; polyester fibers; nylon fibers; ceramic fibers; raw or regenerated bamboo fibers; cotton fibers; rayon fibers; linen fibers; ramie fibers; jute fibers; sisal fibers; flax fibers; soybean fibers; corn fibers; hemp fibers; lyocel fibers; wool; lactide and/or glycolide polymers; lactide/glycolide copolymers; silicate fibers; polyamide fibers; feldspar fibers; zeolite fibers, zeolite-containing fibers; acetate fibers; and combinations thereof; and one or more hemostatic agents selected from the group consisting of RL platelets, RL blood cells; fibrin, and fibrinogen; the hemostatic textile capable of activating hemostatic systems in the body when applied to a wound.

In yet another aspect, the present invention is directed to a hemostatic textile, comprising: a material comprising a combination of about 65% by weight glass fibers and about 35% by weight raw or regenerated bamboo fibers; and one or more hemostatic agents selected from the group consisting of RL platelets, RL blood cells, fibrin, and fibrinogen, wherein the RL platelets and the RL blood cells comprise from about 0.1 to about 20 wt% and the fibrin and the fibrinogen comprise from about 0.1 to about 5 wt%, based on the total weight of the textile; the hemostatic textile capable of activating hemostatic systems in the body when applied to a wound.

In yet another aspect, the present invention is directed to a hemostatic textile, comprising: a material comprising glass fibers and one or more secondary fibers selected from the group consisting of silk fibers; polyester fibers; nylon fibers; ceramic fibers; raw or regenerated bamboo fibers; cotton fibers; rayon fibers; linen fibers; ramie fibers; jute fibers; sisal fibers; flax fibers; soybean fibers; corn fibers; hemp fibers; lyocel fibers; wool; lactide and/or glycolide polymers; lactide/glycolide copolymers; silicate fibers; polyamide fibers; feldspar fibers; zeolite fibers, zeolite-containing fibers; acetate fibers; and combinations thereof; and thrombin or a fraction containing thrombin; and one or more hemostatic agents selected from the group consisting of RL platelets, RL blood cells;

fibrin, and fibrinogen; the hemostatic textile capable of activating hemostatic systems in the body when applied to a wound.

In yet another aspect, the present invention is directed to a hemostatic textile, comprising: a material comprising a combination of about 65% by weight glass fibers and
5 about 35% by weight raw or regenerated bamboo fibers; from about 0.1 to about 5% by weight of thrombin or a fraction comprising thrombin based on the total weight of the textile; and one or more hemostatic agents selected from the group consisting of RL
platelets, RL blood cells, fibrin, and fibrinogen, wherein the RL platelets and the RL blood cells comprise from about 0.1 to about 20 wt% and the fibrin and the fibrinogen comprise
10 from about 0.1 to about 5 wt%, based on the total weight of the textile; the hemostatic textile capable of activating hemostatic systems in the body when applied to a wound.

In yet another aspect, the present invention is directed to a method of preparing a hemostatic textile, comprising the steps of: (1) contacting a material comprising glass fibers and one or more secondary fibers selected from the group consisting of silk fibers;
15 polyester fibers; nylon fibers; ceramic fibers; raw or regenerated bamboo fibers; cotton fibers; rayon fibers; linen fibers; ramie fibers; jute fibers; sisal fibers; flax fibers; soybean fibers; corn fibers; hemp fibers; lyocel fibers; wool; lactide and/or glycolide polymers; lactide/glycolide copolymers; silicate fibers; polyamide fibers; feldspar fibers; zeolite fibers, zeolite-containing fibers; acetate fibers; and combinations thereof with thrombin or
20 a fraction comprising thrombin and optionally a hemostatic agent selected from the group consisting of RL platelets, RL blood cells; fibrin, fibrinogen, and combinations thereof; to form a wet matrix; and (2) drying the wet matrix to produce the hemostatic textile.

In yet another embodiment, the present invention is directed to a method of preparing a hemostatic textile, comprising the steps of: (1) contacting a material
25 comprising glass fibers and one or more secondary fibers selected from the group consisting of silk fibers; polyester fibers; nylon fibers; ceramic fibers; raw or regenerated bamboo fibers; cotton fibers; rayon fibers; linen fibers; ramie fibers; jute fibers; sisal fibers; flax fibers; soybean fibers; corn fibers; hemp fibers; lyocel fibers; wool; lactide and/or glycolide polymers; lactide/glycolide copolymers; silicate fibers; polyamide fibers;
30 feldspar fibers; zeolite fibers, zeolite-containing fibers; acetate fibers; and combinations thereof with platelet rich plasma containing platelets; (2) crosslinking the platelets; and (3) optionally contacting the textile with thrombin or a fraction comprising thrombin to produce the hemostatic textile.

These and other aspects will become apparent upon reading the following detailed description of the invention.

BRIEF DESCRIPTION OF THE FIGURES

5 The invention will be better understood when taken in conjunction with the following figures in which:

 Figure 1 shows representative thrombin generation curves using one embodiment of the present invention;

 Figure 2 shows times for thrombin generation using embodiments of the present
10 invention;

 Figure 3 shows thromboelastographic analysis of materials according to the present invention;

 Figure 4 shows a comparison of blood cells on dual fiber and gauze;

 Figure 5 shows the interaction of red blood cells (RBCs) with materials according
15 to the present invention;

 Figure 6 shows platelet activation on glass filaments used in the present invention;
and

 Figure 7 shows total blood loss using the materials of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

The inventors of the present invention have unexpectedly found that a hemostatic textile can be prepared from a composite of glass fibers and one or more secondary fibers. The hemostatic textile made from the composite of fibers displays excellent hemostatic properties and fluid absorbency. To further enhance the hemostatic properties of the hemostatic textile made from the composite, additional blood factors such as thrombin, lyophilized blood cells, lyophilized platelets, fibrin, fibrinogen, or combinations of these, may be added. These additional factors aid in activating the body's natural hemostasis cascade and result in a material that can rapidly arrest bleeding. The inventors have discovered that the combination of glass fibers, secondary fibers, and additional blood factors produce a novel hemostatic textile that rapidly arrests bleeding, and is useful in situations where large hemorrhages exist or when a patient cannot be immediately admitted to a hospital or trauma treatment center.

The hemostatic textile of the present invention provides important advantages over current products that activate hemostasis. The present invention is capable of rapidly activating the body's natural hemostatic systems, such as the blood coagulation cascade, by providing locally high concentrations of substances that activate that cascade. In addition, by using lyophilized blood proteins, the hemostatic textile of the present invention may be stored in a dry state ready for immediate use for long periods of time. This aspect is particularly advantageous because previous products and systems required hydrated proteins for activation.

As indicated above, one embodiment of the present invention is a hemostatic textile matrix, comprising a material comprising a combination of glass fibers and one or more secondary fibers. Each of these components is discussed in more detail below.

The glass fiber component is preferably a fiberglass prepared by extrusion or electrospinning processes, and has fiber diameters from 5 nanometers to 15 microns. Types of glass contemplated for use in the present invention include but are not limited to alumino-borosilicate glasses with low sodium oxide content, borosilicate glass, lead glass, aluminosilicate, alkali-barium silicate, vitreous silica, chalcogenide glass, phosphate glass, and bioactive glass sold under the trade name "BIOGLASS". The dimensions of the glass fiber component may be described by conventional nomenclature, including the following designations: B (3.5 micron diameter); C (4.5 micron diameter); D (5 micron diameter); DE (6 micron diameter); E (7 micron diameter); G (9 micron diameter); H (10 micron

diameter); or K (13 micron diameter). In addition, strand count of the glass fiber component can range from 900 to 37. The grade of the glass fiber may be any of electrical grade ("E"), chemical grade ("C"), or high strength ("S"), and the filaments may be in any arrangement, for example continuous, staple, or textured. The fiberglass fibers may also
5 be used singly or in a plied state using 2 to 20 or more fibers. Fiberglass material is available commercially from various suppliers such as Owens Corning, and is available commercially as Grades G75, E-grade fiberglass, and the like, using the designations described above.

Secondary fibers used in the textile of the invention include generally any other
10 fiber that can be combined with the glass fibers to impart absorbency, softness, and additional hemostatic activity to the textile. As explained in more detail below, use of secondary fibers with excellent absorbency also aids in incorporating additional hemostatic factors to the textile. Examples of useful secondary fibers include, but are not limited to, silk fibers; polyester fibers; nylon fibers; ceramic fibers; polysaccharide fibers
15 including plant fibers such as raw or regenerated (e.g., chemically processed) bamboo, cotton, rayon, linen, ramie, jute, sisal, flax, soybean, corn, hemp, and lyocel; animal fibers such as wool; lactide and/or glycolide polymers; lactide/glycolide copolymers; silicate fibers; polyamide fibers; feldspar fibers; zeolite fibers, zeolite-containing fibers; acetate fibers; plant fibers that have been genetically engineered to express mammalian
20 coagulation proteins or mammalian vasoactive factors. Other secondary fibers that are suitable for use in the present invention are fibers that have been covalently modified with polymers to promote water absorbency (e.g., polyvinyl alcohols) and polymers that contain molecular moieties that activate hemostatic systems (e.g., linear or cyclized - arginine-glycine-aspartate- moieties such as those found in eptifibatide). Preferred
25 secondary fibers include plant fibers such as raw or regenerated (e.g., chemically processed) bamboo fibers, cotton fibers, and the like, that have high moisture absorbency and that are capable of activating the intrinsic coagulation cascade. The secondary fibers may be prepared using conventional methods, including ring, open end (OE), rotor, or air jet spinning, and may have counts ranging from 1/1 to 100/1 Ne.

30 As will be appreciated by one of skill in the art, the secondary fibers may be used singly, or in combinations of two, three, four, or more in a blended or plied state. In addition, any type of combination of secondary fibers may be used. For example, in one embodiment, two or more secondary fibers may be individually produced and then

blended or plied together to form a composite yarn. In another embodiment, the secondary fibers may be formed as a conjugate comprising blocks of the selected types of fibers, for example alternating blocks of polyesters and polysaccharides. In yet another embodiment, the secondary fibers may be formed as a homogeneous combination of
5 different threads.

The relative amounts of glass fibers and secondary fibers can range widely, for example from about 0.1 to 99.9 wt% glass fibers and about 99.9% to 0.1% by weight secondary fibers, based on the total weight of the dried textile. Preferable amounts of these materials range from about 30 to 80 wt% glass fibers and about 70 to 20 wt%
10 secondary fibers, and more preferably from about 50 to 80 wt% glass fibers to about 50 to 20 wt% secondary fibers. Examples of useful proportions of glass and secondary fibers in the hemostatic textile of the invention include about 50 wt% glass fibers and about 50 wt% secondary fibers; about 40 wt% glass fibers and about 60 wt% secondary fibers; about 30 wt% glass fibers and about 70 wt% secondary fibers; or about 20 wt% glass fibers and
15 about 80 wt% secondary fibers. One particularly useful combination is about 65% by weight glass fibers and 35% by weight bamboo fibers. The glass fiber component and the secondary fiber component may be combined using conventional methods such as spinning, weaving or knitting, or may be used in a nonwoven state.

In use, the hemostatic textile of the invention may take any configuration. In one
20 embodiment, the hemostatic textile consists of a hemostatic layer designed to accelerate hemostasis, and an outer layer designed for surface texture, moisture transfer, fluid adsorption and microbial protection. In another embodiment, the hemostatic textile consists of three layers: a hemostatic layer designed to accelerate hemostasis, a middle layer for bandage strength and elasticity, and an outer layer for designed for surface
25 texture, moisture transfer, fluid adsorption and microbial protection. Additional configurations may be conceived by those of skill in the art.

The hemostatic textile of the invention may also be treated with various agents that enhance its effectiveness. Examples of additional agents include organic or inorganic compounds that are microstatic or microcidal; organic or inorganic compounds that
30 covalently react with blood coagulation proteins; organic or inorganic compounds that covalently react with wounded tissue to form covalent bonds for enhanced adhesion to tissues; organic or inorganic compounds that polymerize to form a three-dimensional polymer network at or on the wound; imaging agents such as ultrasound contrast agents

(e.g., gas-filled microbubbles, metallic nanoparticles, and the like), radio-opaque agents (e.g., iodinated small molecules such as iopromide, iodinated high molecular weight polymers, and the like), magnetic resonance probes (e.g., ferumoxide iron nanoparticles, superparamagnetic metallic nanoparticles, diethylenetriaminepentaacetate (DTPA)-
5 chelated gadolinium, and polymers that contain DTPA-chelated gadolinium, and the like).

Further additional agents that may be included in the hemostatic textile of the invention include skin conditioners such as aloe vera, vitamin E, coenzyme Q, collagen, and the like; anti-inflammatory agents such as aspirin, ibuprofen, acetaminophen, vitamin C, COX-2 inhibitors, steroids, and the like; analgesics such as lidocaine, tetrocaine,
10 opiates, cocaine, antihistamines, and the like; antimicrobial or antifungal agents such as bacitracin, silver salts, iodide, and the like; vasoconstrictors such as epinephrine, norepinephrine, vasopressin, hemoglobin, endothelins, thromboxanes, NO scavengers, and the like; growth factors such as MMP inhibitors, PDGF, and the like; anti-scar agents such as IL-11, anti-keloid compounds, and the like; cauterizing agents that undergo an
15 exothermic reaction upon rehydration such as zeolites; dehydrating agents that are hydroscopic such dextran; prothrombotic agents, such as zeolite, dextran sulfate, polyphosphate, mineral interfaces, phosphatidyl serine, calcium, and the like.

The textile matrix of the invention may also include additional factors that act to activate the body's natural hemostatic systems and thus aid in quickly arresting bleeding.
20 Such additional factors include thrombin or a plasma fraction that includes thrombin, rehydrated lyophilized (RL) platelets, RL blood cells, fibrin, fibrinogen, and combinations of these. In one preferred embodiment, thrombin is incorporated into the textile to impart additional hemostatic action. The thrombin can be from any source (naturally isolated, recombinant, etc.) or may be in the form of a plasma fraction or serum that contains
25 thrombin and additional coagulation factors such as factor XII, factor XIIa, factor XI, factor XIa, factor XIII, factor XIIIa, factor IX, factor IXa, factor VIII, factor VIIIa, factor vWF, factor V, factor Va, factor X, factor Xa, and combinations thereof, or other coagulation cofactors such as components of animal venom, such as reptilase, or vasoactive agents such as endothelins, thromboxanes, nitrous oxide (NO) scavengers, or
30 combinations thereof. These factors, or any of the factors listed above, may be in a dry or liquid form when incorporated into the textile of the invention.

The thrombin contemplated for use in the textile of the invention may take any form including highly purified thrombin IIa from human or animal sources, genetically

modified plants, or other natural or recombinant protein expression systems. In addition, partially purified thrombin from human or animal sources, genetically modified plants, or other natural or recombinant protein expression systems may be used in the present invention. The thrombin contemplated for use in the present invention may also be
5 contained in purified or partially purified serum or plasma. In one embodiment, the thrombin used in the textile of the present invention is a partially purified serum fraction containing thrombin IIa.

The preferred amount of thrombin in the textile of the invention ranges from about 0.01% by weight to about 10% by weight, based on the total weight of the dry textile.

10 More preferred amounts of thrombin included in the textile of the invention range from about 0.05% by weight to about 7% by weight, and most preferably from about 0.1% by weight to about 5% by weight, all based on the total weight of the dry textile.

As explained in more detail in the Examples below, to produce a hemostatic textile that includes thrombin, the textile matrix is soaked in a solution containing thrombin, and
15 frozen and lyophilized. Preservatives such as glycerol, propanediol, polyoxyethylene glycol (PEG) trehalose, and the like, may be included in the soaking solution to prevent the textile from becoming brittle or chalky during lyophilization. In general, preservative concentrations in the thrombin solution range to a maximum of about 20% (v/v). In preferred embodiments, about 12% (v/v) glycerol is used.

20 In another preferred embodiment, one or more of rehydrated lyophilized (RL) platelets, RL blood cells, fibrin or fibrinogen are incorporated into the textile to impart additional hemostatic action. Rehydrated lyophilized blood cells and rehydrated platelets and methods of their manufacture are known in the art. See, for example, U.S. Patent No. 4,287,087; 5,651,966; 5,891,393; 5,902,608; 5,993,804; all incorporated by reference
25 herein. Briefly, RL platelets are made by isolating the platelets, exposing them to a fixative such as formaldehyde, and drying. RL platelets may also be purchased commercially from Entegion, Inc. (Research Triangle Park, NC) under the trade name "STASIX". Methods of isolation and purification of fibrin and fibrinogen are also known in the art.

30 Briefly, to produce RL blood cells, blood can be obtained from healthy volunteers, following signed informed consent, in citrate-phosphate-dextrose with adenine (CPDA-1) and subjected to centrifugation at 1000 xg for 20 min to obtain RBCs. The erythrocytes are diluted to a hematocrit = 5% in phosphate buffered saline (PBS) and centrifuged at

2,000 xg for 10 min. This step can be repeated two additional times to separate RBCs from plasma proteins. RBCs may then be cross-linked with glutaraldehyde (for glut-RL RBCs) or a mixture of paraformaldehyde and glutaraldehyde (for para-RL RBCs). Unreacted aldehyde can be removed from the RBCs by centrifugation (as for the removal
5 of the cells from plasma proteins), and finally the cells are frozen and lyophilized at -30°C.

Fibrin and fibrinogen are also available commercially from various sources. For example, clinical grade material is sold under the tradename HAEMOCOMPLETTAN P from ZLB Behring (Marburg, Germany) and TISSEEL from Baxter (Deerfield, IL USA). Research grade material is available from Enzyme Research Laboratories (South Bend, IN
10 USA). Fibrin and fibrinogen may also be isolated according to procedures known in the art (e.g., van Ruijven-Vermeer IA, et al., Hoppe Seylers Z Physiol Chem. 360:633-7 (1979)). Fibrin and fibrinogen may also be isolated using glycine, ammonium sulfate, or ethanol precipitations that are known in the art.

The RL platelets, RL blood cells, fibrin, or fibrinogen, may be added in powder
15 form by sprinkling or blowing the dried material onto the matrix and freeze-drying. Alternatively, these materials may be added to the matrix in solution form, and frozen and dried as described above. Preservatives such as glycerol, propanediol, polyoxyethylene glycol (PEG) trehalose, and the like, may be included in the soaking solution to prevent the textile from becoming brittle or chalky during lyophilization. In general, preservative
20 concentrations in the thrombin solution range to a maximum of about 20% (v/v). In preferred embodiments, 12% (v/v) glycerol is used.

Any combination of RL blood cells, RL platelets, fibrin and/or fibrinogen may be incorporated into the textile of the present invention. Preferably, the total amount of RL blood cells, RL platelets, fibrin and/or fibrinogen ranges from about 0.1% to about 50%
25 based on the total weight of the dried textile. In exemplary embodiments, the hemostatic textile of the invention may include the following combinations (all weight percents are expressed based on the total weight of the dried textile):

Range	RL Platelets or RL Blood Cells (wt%)	Fibrin or Fibrinogen (wt%)
Preferred Range	0.1 to 20	0.1 to 5
More Preferred Range	1.0 to 10	0.5 to 2
Most Preferred Range	3 to 7	0.75 to 1.5

In yet another embodiment, the textile matrix of the invention includes both thrombin or a fraction containing thrombin and one or more of rehydrated lyophilized (RL) platelets, RL blood cells, fibrin or fibrinogen. For example, one preferred combination of dried platelets, fibrinogen and thrombin is about 3 to 7 wt% RL platelets, 0.75 to 1.5 wt%
5 fibrinogen, and 0.1 to 5 wt% thrombin, all based on the total weight of the dried textile. In one particularly preferred embodiment, a combination of about 5 wt% RL platelets, about 1 wt% fibrinogen, and about 0.1 wt% thrombin is used.

A hemostatic textile that contains both thrombin and one or more of rehydrated lyophilized (RL) platelets, RL blood cells, fibrin or fibrinogen is preferably made by first
10 incorporating thrombin into the matrix followed by incorporation of one or more of rehydrated lyophilized (RL) platelets, RL blood cells, fibrin or fibrinogen using the techniques described generally above. In one embodiment, the hemostatic textile of the invention may be infused with a combination of fibrinogen and thrombin as disclosed in U.S. Patent No. 6,113,948, incorporated herein by reference, and available from ProFibrix
15 BV (Leiderdorp, The Netherlands) under the trade name "FIBROCAPS" (a combination of fibrinogen microspheres and thrombin microspheres). Preservatives such as glycerol, propanediol, polyoxyethylene glycol (PEG) trehalose, and the like, may be included in the soaking solution to prevent the textile from becoming brittle or chalky during lyophilization. In general, preservative concentrations in the thrombin solution range to a
20 maximum of about 20% (v/v). In preferred embodiments, 12% (v/v) glycerol is used.

Generally, the hemostatic textile of the invention is made by the following steps:

1. RL platelets or RL blood cells are prepared and lyophilized according to published procedures;
2. The hemostatic textile is manufactured from textile components. During
25 this step, the textile may be treated chemically by addition of a defined amount of agents such as glycerol, propanediol, polyoxyethylene glycol (PEG) to preserve the textile and aid in adhesion of hemostatic proteins. Additionally, in this step, thrombin-containing serum or plasma is freeze-dried onto the textile matrix.
3. Hemostatic proteins such as RL platelets, RL blood cells, fibrin, or
30 fibrinogen are applied directly to a selected surface of the hemostatic textile (e.g., a surface that will contact wounded tissue) at a pre-selected particle density (protein per square area of textile surface) or weight percentage based on the total weight of the textile. The hemostatic proteins may be applied in any order, and may be applied to the textile in

solution form or in a dry form. In one embodiment, RL platelets may be aldehyde-stabilized, applied to the textile in a liquid state, and then freeze dried onto the textile.

4. The infused hemostatic textile is packaged and optionally subjected to sterilization (e.g., gamma or UV irradiation).

5 Detailed examples of hemostatic textiles and their method of manufacture are outlined below.

The textile matrix of the invention is capable of activating hemostatic systems in the body when applied to a wound, including the blood coagulation systems and vasoconstriction systems. It has long been known that various materials activate platelets and other blood coagulation factors when they come into contact with a wound site. Platelets, as a primary cellular component of blood that provide hemostasis in response to vascular injury, become contact-activated when exposed to foreign materials such as metals glass, and plastics. See, for example, Barr, H. The stickiness of platelets. *Lancet* ii, 775 (1941)). In addition, it is well known that thrombin converts fibrinogen to fibrin in the blood clotting cascade. The combination of components in the hemostatic textile of the present invention act together locally and synergistically to activate the blood coagulation cascade in a highly concentrated and localized form when applied to a wound.

The hemostatic textile of the invention is useful as a wound dressing, for example, a bandage, gauze, and the like, or may be shaped into sutures for use in surgery. Additional uses include forming the hemostatic textile of the invention into fabrics for use in the manufacture of protective clothing or liners for clothing, or for use in tourniquets. Additionally, in another embodiment, the hemostatic textile of the present invention is in the form of a kit for use in surgery or emergency or trauma situations. The kit includes the hemostatic textile of the invention in rolls, sheets, or other appropriate shape, and may be used with or without the additional blood factors.

EXAMPLES

The following examples are intended to illustrate, but in no way limit the scope of the present invention. All parts and percentages are by weight and all temperatures are in degrees Celsius unless explicitly stated otherwise.

5

Materials

The following solutions were used in the Examples described below.

Anticoagulant Citrate Dextrose (ACD): 0.042 M $\text{Na}_3\text{Citrate}$, 0.035 M citric acid, 20% (w/v) anhydrous dextrose, pH to 4.5.

10

Citrated Saline: 6.2 mM $\text{Na}_3\text{Citrate}$, 150 mM NaCl , pH 6.5.

Imidazole Buffered Saline: 84 mM imidazole, 150 mM NaCl , pH 6.8.

15

4% Paraformaldehyde: 20 grams paraformaldehyde and 9.4 grams NaH_2PO_4 are suspended in 400 ml deionized H_2O and heated to about 60°C in a water bath until dissolved. pH is set to 7.2 and water is added to 500 ml.

Fixative Solution (prepared immediately before use): Combine 1 ml ACD, 10 ml 0.135

20

Molar NaH_2PO_4 , pH = 6.5, and 9 ml 4% (w/v) paraformaldehyde.

Imidazole Buffer: 84 mM imidazole, pH = 6.8

Citrate Stock: 3.2% sodium citrate, pH = 7.4

25

Examples 1-7: Preparation of Hemostatic Textiles

The following specific textile combinations was made and used in the experiments that follow:

30

Textile 1: Woven style; G75 fiberglass in warp; 30/1 100% Bamboo Rayon OE in the Fill

The above combination was a glass fiber/bamboo co-weave with the glass fibers (G75, electronic grade E225 spun yarn from E-grade extruded glass) in the "long" orientation (warp) and the bamboo fibers running "across" the fabric (fill).

5 Textile 2: Woven Style; ECBC150 1/0 1.0 Z Fiberglass in warp; 18/1 100%
Bamboo Rayon MJS in the fill.

Textile 3: Woven Style; ECE225 2/0 4.0 Z Fiberglass in warp; 18/3 100%
Bamboo Rayon RS in the fill.

Lyocel MJS in the fill.

Example 8: Preparation of a Hemostatic Textile Matrix that includes Thrombin

120 mg angel hair grade glass fiber was combined with 8 ml plasma (Innovative Research, Inc., Southfield, MI) and 80 µl of 1M CaCl₂ and placed on rocker. The mixture
20 was mixed gently on the rocker for about 90 minutes, and the glass fiber separated from
the mixture by centrifugation (300 xg for 5 minutes). The supernatant was collected and
glycerol was added to a final concentration of 9% by weight. The final product is a serum
that contains thrombin IIa.

50 cm² of Textile 1 above was soaked for about 1 minute in approximately 5 ml of
25 the above serum. Excess serum was allowed to drain off, and the soaked textile matrix
was frozen at -20°C and lyophilized.

Example 9: Preparation of a Hemostatic Textile Matrix that includes Thrombin and an additional Hemostatic Agent

30 A. Textile Matrix that includes Thrombin and Rehydrated Lyophilized (RL)
Platelets

Two methods for preparing textile-based hemostatic matrixes with rehydrated lyophilized (RL) platelets and thrombin are detailed here. The quality of preparations may be evaluated using the Thrombin Generation Analysis described below.

1. Method 1

5 In this method, RL platelets are manufactured separately, then added to the textile matrix.

(a). Preparation of RL Platelets

RL platelets are prepared as described in U.S. Patent Nos. 5,651,966 and 6,139,878, herein incorporated by reference. Alternatively, the following procedure may be used:

10 Platelet rich plasma (PRP) is prepared by first drawing fresh venous blood into ACD (e.g., 42.5 ml blood into 7.5 ml ACD in a 50 cc syringe). The blood is subjected to centrifugation (10 minutes, 1,200 rpm at 25-27°C) to layer the red blood cells. The PRP is found in the supernatant. Alternatively, PRP can be isolated from stored and/or outdated platelets by removing the cells from the storage bag and centrifuging for 10 minutes at
15 about 1200 rpm to remove contaminating red blood cells and aggregated platelets.

Plasma proteins are removed from PRP using centrifugation (10 minutes at about 2400 rpm), and resuspending the isolated platelets in citrated saline buffer. The platelets are washed twice in citrated saline buffer, and resuspended in citrated saline buffer to a final concentration of about 8×10^9 platelets/ml. Alternatively, plasma proteins may be
20 removed from PRP using sizing chromatography (Sephacrose 4B equilibrated with citrated saline buffer). Turbid fractions can be collected, combined, and platelets isolated by centrifugation. The platelets are then resuspended in citrated saline buffer to a final concentration of about 8×10^9 platelets/ml.

The isolated platelets are cross-linked by adding dropwise 3.5 ml of fixative
25 solution to 1.25 ml of isolated platelets at a concentration of about 8×10^9 platelets/ml with gentle stirring. Fixative solution is added to a final volume of about 10 ml, and the mixture is incubated for 1 hour at room temperature without stirring or agitation. The cross-linked platelets are isolated by centrifugation (10 min at 2400 rpm), and resuspended in imidazole buffered saline, washed, and finally resuspended in imidazole buffered saline
30 to a final concentration of about 1×10^9 platelets/ml.

The crosslinked platelets are frozen and lyophilized by first suspending them in imidazole buffered saline with 5% bovine serum albumin at pH 6.8 to a final platelet concentration of about 0.8×10^9 platelets/ml. The mixture is distributed into 1 ml aliquots,

frozen at -80°C, and lyophilized overnight or longer. The lyophilized product may be stored at -20°C. The lyophilized cross-linked platelets may be rehydrated by resuspending in imidazole buffer.

(b). Addition of RL platelets to a Matrix.

5 To prepare a matrix that contains RL platelets, RL platelets are first milled in the dry state to a fine powder. The fine powder is sprinkled evenly onto a flat sterile surface, such as a Petri dish and one side of the freeze-dried thrombin-loaded matrix prepared in Example 8 above is pressed onto the RL powder and removed. The powdered RL platelets may also be blown into the textile using known blowing techniques. As an
10 alternative method, RL platelets can be prepared without freeze-drying and in the absence of serum albumin, and resuspended in the thrombin serum prepared in Example 8 above. Soaking the desired matrix in this solution produces the final product. As a second alternative, rehydrated RL platelets can be resuspended in the thrombin serum described in Example 8 above and used to soak the desired matrix to product the final product.

15 2. Method 2

In this method, the RL platelets are aldehyde-stabilized after binding to the textile matrix, as a component of the matrix. The principle here is to first allow the platelets to contact-activate and adhere to the matrix through normal interactive processes between the hemostatic cells and the textile fibers. The platelets and textile matrix is then taken
20 through the aldehyde stabilization process together. This method includes the following steps:

(a) Platelet rich plasma (PRP) is prepared as described above or alternatively obtain normally liquid stored platelet rich plasma.

(b) The platelet rich plasma is incubated with a quantity of the textile
25 matrix that has been predetermined to bind 90% of the platelets. To predetermine the extent of binding, a sample of matrix is incubated with excess platelets (more than enough to saturate the matrix) and the amount of platelets left in the mixture after the matrix is removed is calculated.

(c) The matrix is removed from the PRP and the platelet concentration
30 in the residual fluid is measured.

(d) The textile is incubated in a 10x volume of citrated saline for 5 min on a rocker and excess fluid is drained. This step is repeated three times. The soaked

textile matrix is then placed in an appropriate volume of citrated saline for a bound textile platelet count of 8×10^9 platelets/ml for use in the crosslinking step described below.

5 (c) 3.5 ml of fixative solution is dropwise added to 1.25 ml soaked platelet-matrix (at 8×10^9 platelets/ml) with gentle swirling to mix. The mixture is further diluted to a final volume of 10 ml with a faster addition of fixative solution for a final bound textile platelet count of 1×10^9 platelets/ml. Incubation is performed for 1 hr at room temperature without stirring or agitation. Finally, the platelet-textile matrix is diluted into a ten volumes of imidazole buffered saline and incubated for 5 min on a rocker, and excess fluid is drained off. This step is repeated three times.

10 (f) To include thrombin, excess imidazole buffered saline is removed from the platelet-textile matrix as thoroughly as possible and then soaked in excess IIa serum as described above. Excess IIa serum is removed and the textile matrix is frozen and lyophilized as described above.

15 (g) Characterize the freeze-dried hemostatic matrix using thrombin generation analysis (described below).

It will be appreciated by those of skill in the art that although Examples 8 and 9 utilize Textile 1 above to prepare one embodiment of the present invention, any textile combination described herein may alternatively be used (e.g., textiles 2-7 described above).

20 Thrombin Generation Analysis

This procedure follows Fischer, T.H. et al. Synergistic platelet integrin signaling and factor XII activation in poly-N-acetyl glucosamine fiber-mediated hemostasis. *Biomaterials* 26, 5433-43 (2005). Briefly, the kinetics of thrombin generation can be used to reflect the ability of hemostatic matrixes to function as a catalytic surface for components (e.g., factor XII) of the coagulation cascade. In this assay, thrombin (IIa) cleaves the non-fluorescent synthetic substrate peptide- D-Phe-Pro-Arg-ANSNH to generate a fluorescent product. The timecourse for fluorescence generation is followed in a 96-well fluorescent platelet reader in kinetic mode.

25 96 well plates are blocked with 150 μ l 5% BSA and citrated saline overnight at 37°C, then stored at 4°C until use. 4 mm (approx.) diameter pieces of hemostatic matrix are prepared with a 4 mm Trepine punch or razor or sharp scissor. Fluorometric IIa substrate D-Phe-Pro-Arg-ANSNH (Cat #SN-17a- C_6H_{11} from Haematologic Technologies,

Inc., Essex Junction, VT) is diluted 1/200 into plasma, followed by CaCl_2 to a final concentration of 10 mM. The mixtures are placed into a fluorometer and fluorescence (490 nm) measured for approximately two hours. Data are analyzed by plotting the timecourse from each well, and measuring the initial and maximal slope of the relative fluorescence change curve and the time required to obtain the maximal slope. The initial and maximal slopes, together with the time to maximal slope, are the quality metrics. The higher the slopes and the shorter the time to maximal slope the more pro-hemostatic the matrix.

10 Example 10: Preparation of a Dual Fiber Textile

This Example illustrates preparation of a textile made from glass fibers in combination with another selected textile fiber. Two lines of evidence point towards continuous filament glass thread as being a potential component of a hemostatic textile. First, platelets were found to activate and adhere to glass (Barr, H. *Lancet* 238, 609-610 (1941)). As a consequence, glass vessels are generally avoided in the *in vitro* handling of platelets, and binding to glass is a longstanding method for assessing platelet activity (McPherson, J. & Zucker, M.B. *Blood* 47, 55-67 (1976); Tsukada, T. & Ogawa, T. *Rinsho Ketsueki* 14, 777-84 (1973); Cooper, R.G., Cornell, C.N., Muhrer, M.E. & Garb, S. *Tex Rep Biol Med* 27, 955-61 (1969)). Secondly, plasma proteins (Stouffer, J.E. & Lipscomb, H.S. *Endocrinology* 72, 91-4 (1963); Lissitzky, S., Roques, M. & Benevent, M.T. *C R Seances Soc Biol Fil* 154, 396-9 (1960); Bull, H.B. *Biochim Biophys Acta* 19, 464-71 (1956)), FXII (Ratnoff, O.D. & Rosenblum, J.M. *Am J Med* 25, 160-8 (1958)) and fibrinogen (Sit, P.S. & Marchant, R.E. *Thromb Haemost* 82, 1053-60 (1999); Rapoza, R.J. & Horbett, T.A. *J Biomed Mater Res* 24, 1263-87 (1990); Perez-Luna, V.H., Horbett, T.A. & Ratner, B.D. *J Biomed Mater Res* 28, 1111-26 (1994)) being well-studied examples, undergo chemical and physical adsorption processes on foreign surfaces (Silberberg, A. *J. Physical Chem.* 66, 1872-1883 (1962)). FXII (Hageman Factor) was found to be particularly important because it initiates the humoral coagulation at the glass/blood interface (Ratnoff, supra; Ratnoff, O.D. & Margolius, A., Jr. *Trans Assoc Am Physicians* 68, 149-54 (1955)). Platelet activation and turnover of the intrinsic coagulation are highly interrelated mechanisms, in part due to the role platelets play as a catalytic surface for assembly of the Va/Xa complex for thrombin generation. Platelet activation by biomaterials (e.g., via integrin outside-in signaling) can result in surface presentation of

phosphatidylserine, an important component of catalytic complexes for thrombin generation (Fischer, T.H., Connolly, R., Thattai, H.S. & Schwartzberg, S.S. *Microsc Res Tech* **63**, 168-74 (2004)). Factor XII has been found to be peripherally associated with the platelet surface for activation of the intrinsic coagulation pathway in the microenvironment of the cell (Iatridis, P.G., Ferguson, J.H. & Iatridis, S.G. *Thromb Diath Haemorrh* **11**, 355-71 (1964); Shibayama, Y., Reddigari, S. & Kaplan, A.P. *Immunopharmacology* Vol. 32 24-7 (1996)), although the series of proteolytic steps involving factor XII that occurs on the platelet surface are poorly understood. The net effect of the close relationship between XIIa-mediated coagulation and platelet activation is synergism for earlier initiation of fibrin polymerization.

The interaction of fluids with glasses are largely controlled by surface tension phenomena related to hydrophobicity, zeta potential and wettability. There is minimal interaction of fluids with the interior of the filaments. Thus, a second type of more absorptive fiber was sought to compensate for the low fluid transport and absorptivity of glass. A panel of natural and synthetic fibers was tested for tendency to activate platelets and the intrinsic coagulation cascade. A dual fiber product consisting of continuous filament type E-glass and specialty rayon specialty rayon was prepared and tested for hemostatic effectiveness in porcine models for hemorrhage.

Materials Type E continuous filament glass (ECDE 11.6 fiberglass) was provided by Carolina Narrow Fabrics, Inc. (Winston-Salem, NC). Specialty rayon made from bamboo (*Bambusa textilis*) and other natural and synthetic fibers were provided by Cheraw Yarn Mills, Inc. (Cheraw, SC). The dual fiber glass/specialty rayon textile fabric was prepared by Carolina Narrow Fabrics, Inc. (Winston-Salem, NC). Gauze was sourced from Kendall (Mansfield, MA).

Platelet rich Plasma Isolation Peripheral blood from consenting normal volunteers was drawn into citrate anti-coagulant, then platelet rich plasma was isolated with differential centrifugation as detailed in Fischer, T.H. et al. *Biomaterials* **26**, 5433-43 (2005). The platelet concentration in the platelet rich plasma was measured with a Hiska haematological analyzer, and the platelet concentration was adjusted to 150,000 platelets/ul by diluting the sample with platelet free plasma.

Thrombin Generation Kinetics The effect fibers on the kinetics of thrombin generation in platelet rich plasma (at 150,000 platelets/ul) was investigated by following the hydrolysis of the thrombin substrate D-Phe-Pro-Arg-ANSNH to yield a fluorescent reaction product.

5 300 ug of each fiber was tested in 100 ul platelet rich plasma in triplicate with the fluorogenic substrate D-Phe-Pro-Arg-ANSNH. The time-course for thrombin generation was initiated by adding CaCl_2 for 10 mM to each sample. The lag time for thrombin generation was defined as the time point at which the fluorescence increased 10% over the initial baseline value.

10

Thromboelastography Thromboelastographic (TEG) measurements were performed with a TEG-5000 Thrombelastograph Hemostasis Analyzer (Haemoscope Corporation, Niles, IL). The assays were initiated by adding CaCl_2 to 10 mM to platelet rich plasma (at 150,000 platelets/ul) and then immediately transferring 327 ul of the calcified platelet rich plasma to the thromboelastography chamber that contained the materials in 33 ul citrated saline. The final fiber concentration was 3.0 mg/ml. Measurements were performed for one hour in triplicate at 37°C, and then relevant parameters were extracted from the “stiffness” curve.

15

20 Scanning Electron Microscopy SEM analysis on glucosamine-based materials was performed as follows. Whole peripheral blood from normal human volunteers was allowed to flow directly from the venapuncture butterfly onto the dual-fiber textile or gauze so that 1 cm x 1 cm of each material was covered by 2 ml of whole blood. The materials were allowed to incubate for one minute, then diluted to 50 ml with citrated saline + 1 mM EGTA to quench hemostatic processes. The materials were allowed to settle for 5 min with gravity, then rediluted with citrated saline. This process was repeated two more times to obtain each material free of unbound RBCs. After one-minute contact with blood and the multiple cycles of dilution and material/RBC complex settling, glutaraldehyde was added for 0.1% (w/v) and the samples were allowed to incubate at room temperature for one hour. The samples were diluted 1/1 (v/v) with 4% paraformaldehyde for a final concentration of 2%, and then additional glutaraldehyde was added for a final concentration of 0.5%. The initial stabilization step with 0.1% glutaraldehyde has been shown to minimize osmotically driven alterations in red blood

25

30

cell (RBC) morphological due to paraformaldehyde exposure (Fischer, T.H. et al. *Microsc Res Tech* 65, 62-71 (2004)). Samples were stored at 4°C overnight and then examined with a Cambridge S200 scanning electron microscope at 20 kv.

- 5 Measurement of Bound RBCs- 10 mg samples of dual fiber or gauze were directly exposed to 1.0 ml whole peripheral blood and washed as detailed for scanning electron microscopy. The pGlcNAc were then placed in 10 ml distilled water with 1% TX-100 to release hemoglobin from bound RBCs. The samples were centrifuged at 10,000 x g for five minutes, then the absorbance at 414 nm was measured to quantify the total amount of hemoglobin (and thus number of RBCs) associated with each material.
- 10

- Measurement of Extent of RBC Lysis Due to Material Contact 10 mg samples of dual fiber or gauze were exposed to 1.0 ml whole peripheral blood as in the last two sections. After one minute of exposure, the samples were centrifuged at 10,000 x g for five minutes to pellet blood cells and other materials. The optical density at 414 nm was measured to quantify the amount of released hemoglobin in the supernatants, and thus the amount of shed blood.
- 15

- Porcine Brachial Plexis and Femoral Artery Transection Hemorrhage Model 40 to 50 kg mixed breed pigs are anesthetized with isofluorane and then several sensors are placed to follow hemodynamic and vasoactive processes: a pulmonary artery thermo dilution catheter is inserted via the external jugular vein into a pulmonary artery; micromanometer-tipped catheters are positioned via the left femoral vessels into the right atrium and thoracic aorta; a 22 gauge catheter is inserted into the left femoral artery and connected to a withdrawal pump; catheters are positioned via the left femoral vessels.
- 20
- 25

- The hemorrhage-challenge phase of the experiment was performed in two phases. First, the transactional laceration of contralateral brachial arteries was performed. The brachial arteries and two associated ~3 mm diameter veins were surgically exposed. One each side the artery and two veins were completely transected with a single scalpel stroke. Injuries were established in a near simultaneous manner, and then each side was immediately packed with the dual fiber textile or gauze. The penetrating cut-down sites were completely packed with each material and then pressure was held for six minutes. Packing was removed and the amount of shed blood was ascertained as described below.
- 30

Both wounds were then repacked with the dual fiber material to stabilize the animals. The second phase of the experiment proceeded by surgically exposing contralateral the femoral arteries. The two contralateral femoral arteries were transected in a near-simultaneous manner and then the surgical sites were packed with dual fiber textile or gauze. Pressure was held for six minutes, then materials were removed for shed blood determination.

The amount of blood shed into the original packing materials were measured by placing the dual fiber or gauze into one liter of distilled water to lyse RBCs. After two hours of stirring at room temperature and storage at 2°C the optical density at 414 nm was measured to determine the amount of released hemoglobin, and thus the number of shed RBCs and volume blood loss.

Results

Experiments proceeded in three stages. First, candidate materials for formulating the hemostatic textile were identified by measuring the ability of selected fibers to activate hemostatic processes in platelet rich plasma. Secondly, a dual fiber combination was subjected to TEG and SEM analysis to gain insight into the mechanism of function. Finally, the ability of the dual fiber textile to provide hemostasis with porcine hemorrhage models was assessed. Details of these experiments follow.

Activation of Hemostatic System by Candidate Fibers A panel of common textile fibers were analyzed for their ability to activate platelets and accelerate turnover of the intrinsic (contact) coagulation pathway. The behavior of the representative fibers in the fluorogenic thrombin generation assay is depicted in Figure 1. In Figure 1, duplicate samples of glass, specialty rayon or gauze fibers were placed in platelet rich plasma that contained a fluorogenic thrombin substrate and then the thrombin generation timecourse was initiated by adding calcium. Arrows indicate the times for thrombin generation. As shown in Figure 1, exposure of the platelet rich plasma to type E continuous filament glass resulted in thrombin generation in approximately eight minutes. Specialty rayon was less prothrombogenic with thrombin generation occurring in 12 minutes, while gauze fiber was considerably slower.

The behavior of a more expansive panel of fibers is presented in Figure 2. In Figure 2, the indicated fibers were tested as detailed in Figure 1 to measure times for thrombin generation. Error bars represent the standard deviation of duplicate analysis. As

shown in Figure 2, glass and specialty rayon were respectively the first and second most thrombogenic material tested. Chitin and gauze, which are components of products for surface hemostasis, did not strongly accelerate thrombin generation. A prototype bandage was thus constructed from glass and specialty rayon.

5

In Vitro Properties of the Glass/Specialty Rayon Dual Fiber Textile The dual-fiber matrix and gauze were compared in the thromboelastographic analysis with platelet rich plasma depicted in Figure 3. In Figure 3, dual fiber or gauze were placed in the thromboelastographic cuvette with normal saline and then platelet rich plasma and calcium were added to initiate the clot formation timecourse. Normal saline without material was run as a negative control. As shown in Figure 3, the glass/specialty rayon textile was found to significantly accelerate fibrin clot formation as compared to gauze or the saline control. Analysis of the dual fiber matrix and gauze after contact with excess peripheral blood was performed using scanning electron microscopy as shown in Figure 4. In Figure 4, dual fiber or gauze was saturated with excess peripheral blood and then examined with scanning electron microscopy as detailed above. White arrows in the left two dual fiber panels indicate specialty rayon fibers. As shown in Figure 4, the glass/specialty rayon matrix tightly bound significant numbers of RBCs, while these cells only sparsely covered the gauze matrix.

Quantification of the number of RBCs on each matrix is shown in Figure 5. In Figure 5, dual fiber or gauze was saturated with excess peripheral blood, and then the number of bound RBCs was measured as described above. Error bars represent the standard deviation from duplicate measurements. As shown in Figure 5, the dual fiber textile bound approximately ten times as many RBCs as gauze. Significant lysis of RBCs did not occur (data not shown). SEM examination of the dual fiber matrix also showed a large number of highly activated platelets on the continuous glass filament component, as shown in Figure 6, which shows dual fiber saturated and washed with peripheral blood and examined with scanning electron microscopy. These results indicate that the glass/specialty rayon matrix is more effective at providing surface hemostasis than gauze.

30

Ability of the Dual Fiber Bandage to Provide Hemostasis in Porcine Models The dual fiber matrix was compared to gauze in severe porcine large vessel transection injuries. Two types of injuries were established on each of four pigs. First, the brachial artery and

two associated large veins in contralateral plexus areas were completely transected in a near- simultaneous manner. This gives an exsanguinating hemorrhage that is both arterial and venous in nature. The contralateral cut-down/injury sites were immediately packed with as much dual fiber textile or gauze as required to fill the injury site. Pressure was
5 then held for six minutes, and then the sites were unpacked and the degree of hemostasis was judged as complete (with no visible hemorrhage), partial (with less than three ml of blood loss per minute) or uncontrolled (with more than three ml of blood loss per minute). The blood loss onto packing materials and any shed blood was measured from each wound site. The contralateral brachial plexus injury sites were then re-packed with dual fiber
10 textile so as to stabilize the animal for the second set of femoral injuries. Contralateral femoral arteries were exposed, and then completely transected in a near simultaneous manner to initiate an exsanguinating hemorrhage. As with the brachial plexus injuries, the injury sites were immediately packed with dual fiber textile or gauze. After holding pressure for six minutes the sites were unpacked and the degree of hemostasis was judged
15 as described for the brachial injuries. An important feature of this large vessel transection model is that the animals were not in hemorrhagic shock. Because the injuries were immediately packed with pressure, the mean arterial pressure was maintained in the 45 to 55 mm Hg range and total blood loss was not more than ~ 5% of the total blood volume. The total amount of blood loss with the dual fiber material was approximately half as with
20 gauze with both brachial plexus and femoral injuries as shown in Figure 7. In Figure 7, the total amount of material-absorbed and shed blood from the six minute pressure period was measured from the brachial (Left Panel A) and femoral (Right Panel B). Error bars represent the standard deviation of the blood loss from similar injuries in five animals. As shown in Figure 7, there was a marked tendency for gauze to pull off the hemostatic plug
25 (to the extent that there was one), while the dual fiber textile did not strongly incorporate into the hemostatic zone.

The above results show that fundamental principles of hemostasis can be used to design economical materials for surface hemostasis. The glass/specialty rayon textile outperformed gauze in porcine models of both capillary and large vessel injury; bleed
30 times and blood loss were reduced by approximately halve when the fiber component of the textile was optimized with respect to thrombogenicity.

While the invention has been described above with reference to specific embodiments thereof, it is apparent that many changes, modifications, and variations can

be made without departing from the inventive concept disclosed herein. Accordingly, it is intended to embrace all such changes, modifications, and variations that fall within the spirit and broad scope of the appended claims.

CLAIMS

1. A packaged hemostatic textile comprising a textile material comprising glass fibers co-woven or knitted with secondary fibers, wherein said textile material is within a sterilized package, said glass fibers have a diameter from 5 nanometers to 15 microns, and said secondary fibers comprise raw or regenerated bamboo fibers.

2. The packaged hemostatic textile of claim 1, wherein the glass fibers are in the warp and the secondary fibers are in the fill.

3. The packaged hemostatic textile of claim 1, wherein the textile material is capable of activating hemostatic systems in an animal when the textile material is applied to a wound.

4. The packaged hemostatic textile of claim 1, wherein the relative amounts of the glass fibers and the secondary fibers range from about 0.1% to about 99.9% by weight glass fibers and from about 99.9% to about 0.1% by weight secondary fibers, based on the total weight of the textile.

5. The packaged hemostatic textile of claim 1, wherein the relative amounts of the glass fibers and the secondary fibers range from about 50% to about 80% by weight glass fibers and from about 20% to about 50% by weight secondary fibers, based on the total weight of the textile.

6. The packaged hemostatic textile of claim 1, wherein the glass fibers comprise an alumino-borosilicate glass.

7. The packaged hemostatic textile of claim 1, wherein the raw or regenerated bamboo fibers comprise bamboo rayon fibers.

8. The packaged hemostatic textile of claim 1, wherein the package contains a wound dressing bandage comprising the textile material.

9. A packaged hemostatic textile comprising a textile material comprising glass fibers co-woven or knitted with secondary fibers, wherein said textile material is within a sterilized package, said glass fibers are continuous filaments, and said secondary fibers comprise raw or regenerated bamboo fibers.

10. The packaged hemostatic textile of claim 9, wherein the glass fibers have a diameter from 5 nanometers to 15 microns.

11. The packaged hemostatic textile of claim 9 or 6, wherein said raw or regenerated bamboo fibers comprise bamboo rayon fibers.

12. A packaged hemostatic textile comprising a textile material comprising glass fibers co-woven or knitted with secondary fibers, wherein said textile material is within a sterilized package and said secondary fibers comprise raw or regenerated bamboo fibers.

13. A hemostatic textile, comprising a textile material comprising glass fibers co-woven or knitted with raw or regenerated bamboo fibers, further comprising platelets bound to the glass fibers, the raw or regenerated bamboo fibers, or a combination thereof.

14. The hemostatic textile of claim 13, wherein the raw or regenerated bamboo fibers comprise bamboo rayon fibers.

15. The hemostatic textile of claim 13, wherein the relative amounts of the glass fibers and the raw or regenerated bamboo fibers range from about 65% by weight glass fibers and from about 35% by weight raw or regenerated bamboo fibers, based on the total weight of the textile.

16. A hemostatic textile comprising a textile material comprising glass fibers co-woven or knitted with raw or regenerated bamboo fibers, wherein the glass fibers have a diameter from 5 nanometers to 15 microns.

17. The hemostatic textile of claim 16, wherein the glass fibers comprise alumino-borosilicate glasses.

18. The hemostatic textile of claim 16, further comprising platelets bound to the glass fibers, the raw or regenerated bamboo fibers, or a combination thereof.

19. A hemostatic textile, comprising a textile material comprising glass fiber co-woven or knitted with raw or regenerated bamboo fibers, wherein when said textile material is in

contact with a wound on an animal or human and blood from the wound, hemostatic systems are activated in the animal or human, and wherein the glass fibers have a diameter from 5 nanometers to 15 microns.

20. The hemostatic textile of claim 19, wherein the textile material is a nonwoven textile.

21. The hemostatic textile of claim 19, wherein the relative amounts of the glass fibers and the raw or regenerated bamboo fibers range from about 50% to about 80% by weight glass fibers and from about 20% to about 50% by weight raw or regenerated bamboo fibers, based on the total weight of the textile.

22. The hemostatic textile of claim 19, wherein the glass fibers comprise an alumino-borosilicate glass.

23. A hemostatic textile, comprising a textile material comprising glass fibers co-woven or knitted with raw or regenerated bamboo fibers, wherein when said textile material is in contact with a wound on an animal or human and blood from the wound, hemostatic systems are activated in the animal or human, and wherein the glass fibers are continuous filaments.

24. The hemostatic textile of claim 23, wherein the glass fibers have a diameter from 5 nanometers to 15 microns.

25. The hemostatic textile of claim 13, 16, 19, or 23, wherein said raw or regenerated bamboo fibers comprise bamboo rayon fibers.

26. A hemostatic textile, comprising a textile material comprising glass fibers co-woven or knitted with rayon fibers, wherein when said textile material is in contact with a wound on an animal or human and blood from the wound, hemostatic systems are activated in the animal or human, and wherein the textile material further comprises platelets bound to the glass fibers, rayon fibers, or a combination thereof.

27. A hemostatic textile comprising a textile material comprising glass fibers co-woven or knitted with secondary fibers, wherein the relative amounts of the glass fibers and the secondary fibers are 65% by weight glass fibers and 35% by weight secondary fibers, based on the total weight of the textile material.

28. The hemostatic textile of claim 27, wherein the secondary fibers comprise rayon fibers.
