

## BIOMEDICAL DEVICES CONTAINING INTERNAL WETTING AGENTS

## RELATED PATENT APPLICATIONS

This patent application claims priority of a provisional application, U.S.  
5 Ser. No. 60/318,536 which was filed on September 10, 2001.

## FIELD OF THE INVENTION

This invention relates to silicone hydrogels that contain internal wetting  
agents, as well as methods for their production and use.

10

## BACKGROUND OF THE INVENTION

Contact lenses have been used commercially to improve vision since  
at least the 1950s. The first contact lenses were made of hard materials and  
as such were somewhat uncomfortable to users. Modern lenses have been  
15 developed that are made of softer materials, typically hydrogels and  
particularly silicone hydrogels. Silicone hydrogels are water-swollen polymer  
networks that have high oxygen permeability and surfaces that are more  
hydrophobic than hydrophilic. These lenses provide a good level of comfort to  
many lens wearers, but there are some users who experience discomfort and  
20 excessive ocular deposits leading to reduced visual acuity when using these  
lenses. This discomfort and deposits has been attributed to the hydrophobic  
character of the surfaces of lenses and the interaction of those surfaces with  
the protein, lipids and mucin and the hydrophilic surface of the eye.

Others have tried to alleviate this problem by coating the surface of  
25 silicone hydrogel contact lenses with hydrophilic coatings. For example, it has  
been disclosed that silicone hydrogel lenses can be made more compatible  
with ocular surfaces by applying plasma coatings to the lens surface.  
However, uncoated silicone hydrogel lenses having low incidences of surface  
deposits have not been disclosed.

30 Incorporating internal hydrophilic agents (or wetting agents) into a  
macromer containing reaction mixture has been disclosed. However, not all  
silicone containing macromers display compatibility with hydrophilic polymers.  
Modifying the surface of a polymeric article by adding polymerizable  
surfactants to a monomer mix used to form the article has also been

disclosed. However, lasting *in vivo* improvements in wettability and reductions in surface deposits are not likely.

Polyvinylpyrrolidone (PVP) or poly-2-ethyl-2-oxazoline have been added to a hydrogel composition to form an interpenetrating network which shows a low degree of surface friction, a low dehydration rate and a high degree of biodeposit resistance. However, the hydrogel formulations disclosed are conventional hydrogels and there is no disclosure on how to incorporate hydrophobic components, such as siloxane monomers, without losing monomer compatibility.

While it may be possible to incorporate high molecular weight polymers as internal wetting agents into silicone hydrogel lenses, such polymers are difficult to solubilize in reaction mixtures which contain silicones. In order to solubilize these wetting agents, silicone macromers or other prepolymers must be used. These silicone macromers or prepolymers must be prepared in a separate step and then subsequently mixed with the remaining ingredients of the silicone hydrogel formulation. This additional step (or steps) increases the cost and the time it takes to produce these lenses.

Therefore it would be advantageous to find a lens formulation that does not require the use of surface treatment to provide on eye wettability and resistance to surface depositions.

## SUMMARY OF THE INVENTION

The present invention relates to a wettable silicone hydrogel comprising the reaction product of at least one siloxane containing macromer; at least one high molecular weight hydrophilic polymer; and at least one compatibilizing component.

The present invention further relates to a method comprising the steps of (a) mixing reactive components comprising at least one high molecular weight hydrophilic polymer, at least one siloxane containing macromer and an effective amount of at least one compatibilizing component and (b) curing the product of step (a) to form a biomedical device.

The present invention further comprises a method comprising the steps of (a) mixing reactive components comprising a high molecular weight hydrophilic polymer and an effective amount of a compatibilizing component and (b)

curing the product of step (a) at or above a minimum gel time, to form a wettable biomedical device.

The present invention yet further relates to an ophthalmic lens comprising a silicone hydrogel which has, without surface treatment, a tear  
5 film break up time of at least about 7 seconds

The present invention still further relates to a silicone hydrogel contact lens comprising at least one oxygen permeable component, at least one compatibilizing component and an amount of high molecular weight hydrophilic polymer sufficient to provide said device, without a surface  
10 treatment, with tear film break up time after about one day of wear of at least about 7 seconds.

A device comprising a silicone hydrogel contact lens which is substantially free from surface deposition without surface modification.

#### DETAILED DESCRIPTION OF THE INVENTION

15 A biomedical device formed from a reaction mixture comprising, consisting essentially of, or consisting of a silicone containing macromer, at least one high molecular weight hydrophilic polymer and a compatibilizing amount of a compatibilizing component.

It has been surprisingly found that biomedical devices, and particularly  
20 ophthalmic devices having exceptional in vivo or clinical wettability, without surface modification may be made by including an effective amount of a high molecular weight hydrophilic polymer and a compatibilizing amount of a compatibilizing component in a silicone hydrogel formulation. By exceptional wettability we mean a decrease in advancing dynamic contact angle of at  
25 least about 10% and preferably at least about 20% in some embodiments at least about 50% as compared to a similar formulation without any hydrophilic polymer. Prior to the present invention ophthalmic devices formed from silicone hydrogels either had to be surface modified to provide clinical wettability or be formed from at least one silicone containing macromer having  
30 hydroxyl functionality.

As used herein, a "biomedical device" is any article that is designed to be used while either in or on mammalian tissues or fluid and preferably on or in human tissues or fluid. Examples of these devices include but are not limited to catheters, implants, stents, and ophthalmic devices such as

intraocular lenses and contact lenses. The preferred biomedical devices are ophthalmic devices, particularly contact lenses, most particularly contact lenses made from silicone hydrogels.

As used herein, the terms "lens" and "ophthalmic device" refer to devices that reside in or on the eye. These devices can provide optical correction, wound care, drug delivery, diagnostic functionality or cosmetic enhancement or effect or a combination of these properties. The term lens includes but is not limited to soft contact lenses, hard contact lenses, intraocular lenses, overlay lenses, ocular inserts, and optical inserts.

As used herein the term "monomer" is a compound containing at least one polymerizable group and an average molecular weight of about less than 2000 Daltons, as measure via gel permeation chromatography refractive index detection.. Thus, monomers, include dimers and in some cases oligomers, including oligomers made from more than one monomeric unit.

As used herein, the phrase "without a surface treatment" means that the exterior surfaces of the devices of the present invention are not separately treated to improve the wettability of the device. Treatments which may be foregone because of the present invention include, plasma treatments, grafting, coating and the like. However, coatings which provide properties other than improved wettability, such as, but not limited to antimicrobial coatings may be applied to devices of the present invention.

Various molecular weight ranges are disclosed herein. For compounds having discrete molecular structures, the molecular weights reported herein are calculated based upon the molecular formula and reported in gm/mol. For polymers molecular weights (number average) are measured via gel permeation chromatography refractive index detection and reported in Daltons or are measured via kinematic viscosity measurements, as described in Encyclopedia of Polymer Science and Engineering, N-Vinyl Amide Polymers, Second edition, Vol 17, pgs. 198-257, John Wiley & Sons Inc. and reported in K-values.

#### High Molecular Weight Hydrophilic Polymer

As used herein, "high molecular weight hydrophilic polymer" refers to substances having a weight average molecular weight of no less than about

100,000 Daltons, wherein said substances upon incorporation to silicone hydrogel formulations, improve the wettability of the cured silicone hydrogels. The preferred weight average molecular weight of these high molecular weight hydrophilic polymers is greater than about 150,000 Daltons; more  
5 preferably between about 150,000 to about 2,000,000 Daltons, more preferably still between about 300,000 to about 1,800,000 Daltons, most preferably about 500,000 to about 1,500,000 Daltons (all weight average molecular weight).

Alternatively, the molecular weight of hydrophilic polymers of the  
10 invention can be also expressed by the K-value, based on kinematic viscosity measurements, as described in Encyclopedia of Polymer Science and Engineering, N-Vinyl Amide Polymers, Second edition, Vol 17, pgs. 198-257, John Wiley & Sons Inc. When expressed in this manner, hydrophilic  
15 monomers having K-values of greater than about 46 and preferably between about 46 and about 150. The high molecular weight hydrophilic polymers are present in the formulations of these devices in an amount sufficient to provide contact lenses, which without surface modification remain substantially free from surface depositions during use. Typical use periods include at least  
20 about 8 hours, and preferably worn several days in a row, and more preferably for 24 hours or more without removal. Substantially free from surface deposition means that, when viewed with a slit lamp, at least about 80% and preferably at least about 90%, and more preferably about 100% of the lenses worn in the patient population display depositions rated as none or slight, over the wear period.

25 Suitable amounts of high molecular weight hydrophilic polymer include from about 1 to about 15 weight percent, more preferably about 3 to about 15 percent, most preferably about 5 to about 12 percent, all based upon the total weight of all reactive components.

Examples of high molecular weight hydrophilic polymers include but  
30 are not limited to polyamides, polylactones, polyimides, poly lactams and functionalized polyamides, polylactones, polyimides, poly lactams, such as DMA functionalized by copolymerizing DMA with a lesser molar amount of a hydroxyl-functional monomer such as HEMA, and then reacting the hydroxyl groups of the resulting copolymer with materials containing radical

polymerizable groups, such as isocyanatoethylmethacrylate or methacryloyl chloride. Hydrophilic prepolymers made from DMA or N-vinyl pyrrolidone with glycidyl methacrylate may also be used. The glycidyl methacrylate ring can be opened to give a diol which may be used in conjunction with other

5 hydrophilic prepolymer in a mixed system to increase the compatibility of the high molecular weight hydrophilic polymer, hydroxyl-functionalized silicone containing monomer and any other groups which impart compatibility. The preferred high molecular weight hydrophilic polymers are those that contain a cyclic moiety in their backbone, more preferably, a cyclic amide or cyclic

10 imide. High molecular weight hydrophilic polymers include but are not limited to poly-N-vinyl pyrrolidone, poly-N-vinyl-2- piperidone, poly-N-vinyl-2- caprolactam, poly-N-vinyl-3-methyl-2- caprolactam, poly-N-vinyl-3-methyl-2- piperidone, poly-N-vinyl-4-methyl-2- piperidone, poly-N-vinyl-4-methyl-2- caprolactam, poly-N-vinyl-3-ethyl-2- pyrrolidone, and poly-N-vinyl-4,5-

15 dimethyl-2-pyrrolidone, polyvinylimidazole, poly-N-N-dimethylacrylamide, polyvinyl alcohol, polyacrylic acid, polyethylene oxide, poly 2 ethyl oxazoline, heparin polysaccharides, polysaccharides, mixtures and copolymers (including block or random, branched, multichain, comb-shaped or star shaped) thereof where poly-N-vinylpyrrolidone (PVP) is particularly preferred.

20 Copolymers might also be used such as graft copolymers of PVP.

The high molecular weight hydrophilic polymers provide improved wettability, and particularly improved in vivo wettability to the medical devices of the present invention. Without being bound by any theory, it is believed that the high molecular weight hydrophilic polymers are hydrogen bond

25 receivers which in aqueous environments, hydrogen bond to water, thus becoming effectively more hydrophilic. The absence of water facilitates the incorporation of the hydrophilic polymer in the reaction mixture. Aside from the specifically named high molecular weight hydrophilic polymers, it is expected that any high molecular weight polymer will be useful in this

30 invention provided that when said polymer is added to a silicone hydrogel formulation, the hydrophilic polymer (a) does not substantially phase separate from the reaction mixture and (b) imparts wettability to the resulting cured polymer. In some embodiments it is preferred that the high molecular weight hydrophilic polymer be soluble in the diluent at processing temperatures.

Manufacturing processes which use water or water soluble diluents may be preferred due to their simplicity and reduced cost. In these embodiments high molecular weight hydrophilic polymers which are water soluble at processing temperatures are preferred.

5

#### Compatibilizing Component

As used herein a "compatibilizing component" is a compound having a number average molecular weight of about less than 5000 Daltons, and preferably less than about 3000 Daltons, and containing at least one  
10 polymerizable group, which is capable of solubilizing the selected reactive components. Without a compatibilizing component the high molecular weight hydrophilic polymer and oxygen permeable components are insufficiently miscible, and cannot, with reasonable processing conditions, form an optically transparent ophthalmic device. The compatibilizing component of the present  
15 invention solubilizes the oxygen permeable component(s) and high molecular weight hydrophilic polymer via hydrogen bonding, dispersive forces, combinations thereof and the like. Thus any functionality which reacts in any of these ways with the hydrophilic polymer may be used as a compatibilizing component. Macromers (number average molecular weights of between  
20 about 5000 and about 15,000 Daltons) may also be used so long as they have the compatibilizing functionality described herein. If a compatibilizing macromer is used it may still be necessary to add an additional compatibilizing component to get the desired level of wettability in the resulting ophthalmic device.

25 One suitable class of compatibilizing components of the present invention comprise at least one active hydrogen and at least one siloxane group. An active hydrogen has the ability to hydrogen bond with the hydrophilic polymer and any hydrophilic monomers present. Hydroxyl groups readily participate in hydrogen bonding and are therefore a preferred source  
30 of active hydrogens. Thus, in one embodiment, the compatibilizing components of the present invention beneficially comprise at least one hydroxyl group and at least one "-Si-O-Si-"group. It is preferred that silicone and its attached oxygen account for more than about 10 weight percent of

said compatibilizing component, more preferably more than about 20 weight percent.

The ratio of Si to OH in the compatibilizing component is also important to providing a compatibilizing component which will provide the desired degree of compatibilization. If the ratio of hydrophobic portion to OH is too high, the compatibilizing component may be poor at compatibilizing the hydrophilic polymer, resulting in incompatible reaction mixtures. Accordingly, in some embodiments, the Si to OH ratio is less than about 15:1, and preferably between about 1:1 to about 10:1. In some embodiments primary alcohols have provided improved compatibility compared to secondary alcohols. Those of skill in the art will appreciate that the amount and selection of compatibilizing component will depend on how much hydrophilic polymer is needed to achieve the desired wettability and the degree to which the silicone containing monomer is incompatible with the hydrophilic polymer.

Examples of compatibilizing components include monomers of Formulae I and II

wherein:

- n is an integer between 3 and 35, and preferably between 4 and 25;  
 R<sup>1</sup> is hydrogen, C<sub>1-6</sub>alkyl,;  
 R<sup>2</sup>, R<sup>3</sup>, and R<sup>4</sup>, are independently, C<sub>1-6</sub>alkyl, triC<sub>1-6</sub>alkylsiloxy, phenyl, naphthyl, substituted C<sub>1-6</sub>alkyl, substituted phenyl, or substituted naphthyl

where the alkyl substituents are selected from one or more members of the group consisting of C<sub>1-6</sub>alkoxycarbonyl, C<sub>1-6</sub>alkyl, C<sub>1-6</sub>alkoxy, amide, halogen, hydroxyl, carboxyl, C<sub>1-6</sub>alkylcarbonyl and formyl, and where the aromatic substituents are selected from one or more

5 members of the group consisting of C<sub>1-6</sub>alkoxycarbonyl, C<sub>1-6</sub>alkyl, C<sub>1-6</sub>alkoxy, amide, halogen, hydroxyl, carboxyl, C<sub>1-6</sub>alkylcarbonyl and formyl;

R<sup>5</sup> is hydroxyl, an alkyl group containing one or more hydroxyl groups, or (CH<sub>2</sub>(CR<sup>9</sup>R<sup>10</sup>)<sub>y</sub>O)<sub>x</sub>-R<sup>11</sup> wherein y is 1 to 5, preferably 1 to 3, x is an integer of 10 1 to 100, preferably 2 to 90 and more preferably 10 to 25; R<sup>9</sup> - R<sup>11</sup> are independently selected from H, alkyl having up to 10 carbon atoms and alkyls having up to 10 carbon atoms substituted with at least one polar functional group;

15 R<sup>6</sup> is a divalent group comprising up to 20 carbon atoms;

R<sup>7</sup> is a monovalent group that can undergo free radical and/or cationic polymerization comprising up to 20 carbon atoms; and

R<sup>8</sup> is a divalent or trivalent group comprising up to 20 carbon atoms.

20 Reaction mixtures of the present invention may include more than one compatibilizing component.

For monofunctional compatibilizing components the preferred R<sup>1</sup> is hydrogen, and the preferred R<sup>2</sup>, R<sup>3</sup>, and R<sup>4</sup>, are C<sub>1-6</sub>alkyl and triC<sub>1-6</sub>alkylsiloxy, most preferred methyl and trimethylsiloxy. For multifunctional (difunctional or 25 higher) R<sup>1</sup>-R<sup>4</sup> independently comprise ethylenically unsaturated polymerizable groups and more preferably comprise an acrylate, a styryl, a C<sub>1-6</sub>alkylacrylate, acrylamide, C<sub>1-6</sub>alkylacrylamide, N-vinylactam, N-vinylamide, , C<sub>2-12</sub>alkenyl, C<sub>2-12</sub>alkenylphenyl, C<sub>2-12</sub>alkenylnaphthyl, or C<sub>2-6</sub>alkenylphenylC<sub>1-6</sub>alkyl.

The preferred R<sup>5</sup> is hydroxyl, -CH<sub>2</sub>OH or CH<sub>2</sub>CHOHCH<sub>2</sub>OH, with 30 hydroxyl being most preferred..

The preferred R<sup>6</sup> is a divalent C<sub>1-6</sub>alkyl, C<sub>1-6</sub>alkyloxy, C<sub>1-6</sub>alkyloxyC<sub>1-6</sub>alkyl, phenylene, naphthalene, C<sub>1-12</sub>cycloalkyl, C<sub>1-6</sub>alkoxycarbonyl, amide, carboxy, C<sub>1-6</sub>alkylcarbonyl, carbonyl, C<sub>1-6</sub>alkoxy, substituted C<sub>1-6</sub>alkyl, substituted C<sub>1-6</sub>alkyloxy, substituted C<sub>1-6</sub>alkyloxyC<sub>1-6</sub>alkyl,

substituted phenylene, substituted naphthalene, substituted C<sub>1-12</sub>cycloalkyl, where the substituents are selected from one or more members of the group consisting of C<sub>1-6</sub>alkoxycarbonyl, C<sub>1-6</sub>alkyl, C<sub>1-6</sub>alkoxy, amide, halogen, hydroxyl, carboxyl, C<sub>1-6</sub>alkylcarbonyl and formyl. The particularly preferred R<sup>6</sup> is a divalent methyl (methylene).

The preferred R<sup>7</sup> comprises a free radical reactive group, such as an acrylate, a styryl, vinyl, vinyl ether, itaconate group, a C<sub>1-6</sub>alkylacrylate, acrylamide, C<sub>1-6</sub>alkylacrylamide, N-vinylactam, N-vinylamide, C<sub>2-12</sub>alkenyl, C<sub>2-12</sub>alkenylphenyl, C<sub>2-12</sub>alkenylnaphthyl, or C<sub>2-6</sub>alkenylphenylC<sub>1-6</sub>alkyl or a cationic reactive group such as vinyl ether or epoxide groups. The particularly preferred R<sup>7</sup> is methacrylate.

The preferred R<sup>8</sup> is a divalent C<sub>1-6</sub>alkyl, C<sub>1-6</sub>alkyloxy, C<sub>1-6</sub>alkyloxyC<sub>1-6</sub>alkyl, phenylene, naphthalene, C<sub>1-12</sub>cycloalkyl, C<sub>1-6</sub>alkoxycarbonyl, amide, carboxy, C<sub>1-6</sub>alkylcarbonyl, carbonyl, C<sub>1-6</sub>alkoxy, substituted C<sub>1-6</sub>alkyl, substituted C<sub>1-6</sub>alkyloxy, substituted C<sub>1-6</sub>alkyloxyC<sub>1-6</sub>alkyl, substituted phenylene, substituted naphthalene, substituted C<sub>1-12</sub>cycloalkyl, where the substituents are selected from one or more members of the group consisting of C<sub>1-6</sub>alkoxycarbonyl, C<sub>1-6</sub>alkyl, C<sub>1-6</sub>alkoxy, amide, halogen, hydroxyl, carboxyl, C<sub>1-6</sub>alkylcarbonyl and formyl. The particularly preferred R<sup>8</sup> is C<sub>1-6</sub>alkyloxyC<sub>1-6</sub>alkyl.

Examples of compatibilizing component of Formula I that are particularly preferred are 2-propenoic acid, 2-methyl-2-hydroxy-3-[3-[1,3,3,3-tetramethyl-1-[trimethylsilyl]oxy]disiloxanyl]propoxy]propyl ester (which can also be named (3-methacryloxy-2-hydroxypropyloxy)propylbis(trimethylsiloxy)methylsilane).

The above compound, (3-methacryloxy-2-hydroxypropyloxy)propylbis(trimethylsiloxy)methylsilane is formed from an

epoxide, which produces an 80:20 mixture of the compound shown above and (2-methacryloxy-3-hydroxypropyloxy)propylbis(trimethylsiloxy)methylsilane.

In the present invention the 80:20 mixture is preferred over pure (3-methacryloxy-2-hydroxypropyloxy)propylbis(trimethylsiloxy)methylsilane. In

- 5 some embodiments of the present invention it is preferred to have some amount of the primary hydroxyl present, preferably greater than about 10 wt% and more preferably at least about 20 wt%

Other suitable hydroxyl-functionalized silicone containing monomers include (3-methacryloxy-2-hydroxypropyloxy)propyltris(trimethylsiloxy)silane

10

bis-3-methacryloxy-2-hydroxypropyloxypropyl polydimethylsiloxane

5

3-methacryloxy-2-(2-hydroxyethoxy)propyloxypropylbis(trimethylsiloxy)methylsilane

10 N-2-methacryloxyethyl-O-(methyl-bis-trimethylsiloxy-3-propyl)silyl carbamate

N,N,N',N'-tetrakis(3-methacryloxy-2-hydroxypropyl)- $\alpha,\omega$ -bis-3-aminopropyl-polydimethylsiloxane

5

The reaction products of glycidyl methacrylate with amino-functional polydimethylsiloxanes may also be used as a compatibilizing components. Other suitable compatibilizing components include those disclosed in columns 6,7 and 8 of US 5,994,488, and monomers disclosed in 4,259,467; 4,260,725; 4,261,875; 4,649,184; 4,139,513, 4,139,692; US 2002/0016383; 4,139,513 and 4,139,692. These and any other patents or applications cited herein are incorporated by reference.

Still additional structures which may be suitable compatibilizing components include those similar to the compounds disclosed in Pro. ACS Div. Polym. Mat. Sci. Eng., April 13-17, 1997, p. 42, and having the following structure:

20

where  $n = 1-50$  and R independently comprise H or a polymerizable unsaturated group), with at least one R comprising a polymerizable group, and at least one R, and preferably 3-8 R, comprising H.

- 5 A second suitable class of compatibilizing components include those having the structure given in Formula III, below:

Wherein x is 1 to 10;

- 10 IWA is a difunctional hydrophilic polymer as defined below, but having a number average molecular weight of between about 1000 and about 50,000 Daltons; and

- HB is a difunctional moiety comprising at least one N which is capable of hydrogen bonding with active hydrogens in the hydrophilic polymer and any  
15 other component having active hydrogens.

Preferred IWA groups may be derived from  $\alpha,\omega$ -hydroxyl terminated PVP and  $\alpha,\omega$ -hydroxyl terminated polyoxyalkylene glycols having number average molecular weights between about 1,000 and about 50,000 Daltons.

- Preferred HB groups include difunctional amides, imides, carbamates  
20 and ureas, combinations thereof and the like.

Compatibilizing components of Formula III may be made by amine terminated polyoxyalkyleneglycols (Jeffamines) reacted with isocyanates, chloroformates or acyl chlorides or anhydrides.

- Additional suitable compatibilizing components are disclosed in U.S.  
25 Patent 4,235,985 which is hereby incorporated by reference.

- Suitable compatibilizing components may also comprise silicone containing macromers which have been modified to include compatibilizing functionality as defined above. Such macromers comprise substantial quantities of both Si and HB groups as defined, above, or active hydrogen  
30 functionality, such as hydroxyl groups. One class of suitable macromers include hydroxyl functionalized macromers made by Group Transfer Polymerization (GTP), or styrene functionalized prepolymers of hydroxyl functional methacrylates and silicone methacrylates and are disclosed in US6,367,929, which is incorporated herein by reference. In the present

vention, these macromers are preferably used with another compatibilizing component, such as a siloxane containing monomer. Other macromers, such as those made by radical polymerization or condensation reaction may also be used independently or in combination with other compatibilizing components so long as the Si to hydrogen molar ratio (OH) of the macromer is less than about 15:1, and preferably between about 1:1 to about 10:1 or the Si to HB molar ratio is less than about 10:1 and preferably between about 1:1 and about 8:1. However, those of skill in the art will appreciate that including difluoromethylene groups will decrease the molar ratio suitable for providing compatibility.

Suitable monofunctional compatibilizing components are commercially available from Gelest, Inc. Morrisville, PA. Suitable multifunctional compatibilizing components are commercially available from Gelest, Inc, Morrisville, PA or may be made using the procedures disclosed in 5,994,488 and 5,962,548. Suitable PEG type monofunctional compatibilizing components may be made using the procedures disclosed in PCT/JP02/02231.

Suitable compatibilizing macromers may be made using the general procedure disclosed in US 5,760,100 (material C) or US 6,367,929.

While compatibilizing components comprising hydroxyl functionality have been found to be particularly suitable for providing compatible polymers for biomedical devices, and particularly ophthalmic devices, any compatibilizing component which, when polymerized and/or formed into a final article is compatible with the selected hydrophilic components may be used. Compatibilizing components may be selected using the following monomer compatibility test. In this test one gram of each of mono-3-methacryloxypropyl terminated, mono-butyl terminated polydimethylsiloxane (mPDMS MW 800-1000) and a monomer to be tested are mixed together in one gram of 3,7-dimethyl-3-octanol at about 20°C. A mixture of 12 weight parts K-90 PVP and 60 weight parts DMA is added drop-wise to hydrophobic component solution, with stirring, until the solution remains cloudy after three minutes of stirring. The mass of the added blend of PVP and DMA is determined in grams and recorded as the monomer compatibility index. Any compatibilizing component

having a compatibility index of greater than 0.5 grams, more preferably greater than about 1 grams and most preferably greater than about 1.5 grams will be suitable for use in this invention. Those of skill in the art will appreciate that the molecular weight of the active compatibilizing component will effect the results of the above test. Compatibilizing components having molecular weights greater than about 800 daltons may need to mix for longer periods of time to give representative results.

An "effective amount" of the compatibilizing component of the invention is the amount needed to compatibilize or dissolve the high molecular weight hydrophilic polymer and the other components of the polymer formulation. Thus, the amount of compatibilizing component will depend in part on the amount of hydrophilic polymer which is used, with more compatibilizing component being needed to compatibilize higher concentrations of high molecular weight hydrophilic polymer. Effective amounts of compatibilizing component in the polymer formulation include about 5% (weight percent, based on the total weight of the reactive components) to about 90 %, preferably about 10% to about 80%, most preferably, about 20% to about 50%.

In addition to the high molecular weight hydrophilic polymers and the compatibilizing components of the invention other hydrophilic monomers, oxygen permeability enhancing components, crosslinkers, additives, diluents, polymerization initiators may be used to prepare the biomedical devices of the invention.

#### Oxygen Permeable Component

The compositions and devices of the present invention may further comprise additional components which provide enhanced oxygen permeability compared to a conventional hydrogel. Suitable oxygen permeable components include siloxane containing monomers, macromers and reactive prepolymers, fluorine containing monomers, macromers and reactive prepolymers and carbon-carbon triple bond containing monomers, macromers and reactive prepolymers and combinations thereof, but exclude the compatibilizing component. For the purposes of this invention, the term macromer will be used to cover both macromers and prepolymers. Preferred

oxygen permeable components comprise siloxane containing monomers, macromers, and mixtures thereof

Suitable siloxane containing monomers include, amide analogs of TRIS described in U.S. 4,711,943, vinylcarbamate or carbonate analogs described in  
5 U.S. Pat. 5,070,215, and monomers contained in U.S. Pat. 6,020,445 are useful and these aforementioned patents as well as any other patents mentioned in this specification are hereby incorporated by reference. More specifically, 3-methacryloxypropyltris(trimethylsiloxy)silane (TRIS), monomethacryloxypropyl terminated polydimethylsiloxanes,  
10 polydimethylsiloxanes, 3-methacryloxypropylbis(trimethylsiloxy)methylsilane, methacryloxypropylpentamethyl disiloxane and combinations thereof are particularly useful as siloxane containing monomers of the invention. Additional siloxane containing monomers may be present in amounts of about 0 to about 75 wt%, more preferably of about 5 and about 60 and most  
15 preferably of about 10 and 40 weight%.

Suitable siloxane containing macromers have a number average molecular weight between about 5,000 and about 15,000 Daltons. Siloxane containing macromers include materials comprising at least one siloxane group, and preferably at least one dialkyl siloxane group and more preferably  
20 at least one dimethyl siloxane group. The siloxane containing macromers may include other components such as urethane groups, alkylene or alkylene oxide groups, polyoxyalkylene groups, arylene groups, alkyl esters, amide groups, carbamate groups, perfluoroalkoxy groups, isocyanate groups, combinations thereof and the like. A preferred class of siloxane containing  
25 macromers may be formed via the polymerization of one or more siloxanes with one or more acrylic or methacrylic materials. Siloxane containing macromers may be formed via group transfer polymerization ("GTP"), free radical polymerization, condensation reactions and the like. The siloxane containing macromers may be formed in one or a series of steps depending  
30 on the components selected and using conditions known in the art. Specific siloxane containing macromers, and methods for their manufacture, include those disclosed in US 5,760,100 as materials A-D (methacrylate functionalized, silicone-fluoroether urethanes and methacrylate functionalized, silicone urethanes), and those disclosed in US 6,367,929 (styrene

functionalized prepolymers of hydroxyl functional methacrylates and silicone methacrylates), the disclosures of which are incorporated herein by reference.

Suitable siloxane containing reactive prepolymers include vinyl carbamate functionalized polydimethylsiloxane, which is further disclosed in  
5 US 5,070,215 and urethane based prepolymers comprising alternating "hard" segments formed from the reaction of short chained diols and diisocyanates and "soft" segments formed from a relatively high molecular weight polymer, which is  $\alpha,\omega$  endcapped with two active hydrogens. Specific examples of suitable siloxane containing prepolymers, and methods for their manufacture,  
10 are disclosed in US 5,034,461, which is incorporated herein by reference.

The hydrogels of the present invention may comprise at least one siloxane containing macromer. The siloxane containing macromer may be present in amounts between about 5 and about 50 weight%, preferably between about 10 and about 50 weight% and more preferably between about  
15 15 and about 45 weight%, all based upon the total weight of the reactive components.

Suitable fluorine containing monomers include fluorine-containing (meth)acrylates, and more specifically include, for example, fluorine-containing  $C_2$ - $C_{12}$  alkyl esters of (meth)acrylic acid such as 2,2,2-trifluoroethyl  
20 (meth)acrylate, 2,2,2,2',2',2'-hexafluoroisopropyl (meth)acrylate, 2,2,3,3,4,4,4-heptafluorobutyl (meth)acrylate, 2,2,3,3,4,4,5,5,6,6,7,7,8,8,8-pentadecafluorooctyl (meth)acrylate, 2,2,3,3,4,4,5,5,6,6,7,7,8,8,9,9-hexadecafluorononyl (meth)acrylate and the like. Fluorine containing macromers and reactive prepolymers include macromers and prepolymers  
25 which include said fluorine containing monomers.

It has been found that wettability of macromer containing silicone hydrogels may be improved by including at least one hydrophilic polymer and a compatibilizing component. Improved wettability includes a decrease in advancing dynamic contact angle of at least about 10%, and preferably at  
30 least about 20% and in some embodiment a decrease of at least about 50%. In certain embodiments it may be preferred to use mixtures of siloxane containing monomers or mixtures of siloxane containing monomers with siloxane containing macromers or prepolymers.

### Hydrophilic Monomers

Additionally, reactive components of the present invention may also include any hydrophilic monomers used to prepare conventional hydrogels. For example monomers containing acrylic groups ( $\text{CH}_2=\text{CROX}$ , where R is hydrogen or  $\text{C}_{1-6}$ alkyl and X is O or N) or vinyl groups ( $-\text{C}=\text{CH}_2$ ) may be used. Examples of additional hydrophilic monomers are N,N-dimethylacrylamide, 2-hydroxyethyl methacrylate, glycerol monomethacrylate, 2-hydroxyethyl methacrylamide, polyethyleneglycol monomethacrylate, methacrylic acid, acrylic acid, N-vinyl pyrrolidone, N-vinyl-N-methyl acetamide, N-vinyl-N-ethyl acetamide, N-vinyl-N-ethyl formamide, N-vinyl formamide and combinations thereof.

Aside the additional hydrophilic monomers mentioned above, polyoxyethylene polyols having one or more of the terminal hydroxyl groups replaced with a functional group containing a polymerizable double bond may be used. Examples include polyethylene glycol, as disclosed in US 5,484,863, ethoxylated alkyl glucoside, as disclosed in US 5,690,953, US 5,304,584, and ethoxylated bisphenol A, as disclosed in US 5,565,539, reacted with one or more molar equivalents of an end-capping group such as isocyanatoethyl methacrylate, methacrylic anhydride, methacryloyl chloride, vinylbenzoyl chloride, and the like, produce a polyethylene polyol having one or more terminal polymerizable olefinic groups bonded to the polyethylene polyol through linking moieties such as carbamate, urea or ester groups.

Still further examples include the hydrophilic vinyl carbonate or vinyl carbamate monomers disclosed in U.S. Pat. Nos. 5,070,215, the hydrophilic oxazolone monomers disclosed in U.S. Pat. No. 4,910,277, and polydextran.

The preferred additional hydrophilic monomers are N,N-dimethylacrylamide (DMA), 2-hydroxyethyl methacrylate (HEMA), glycerol methacrylate, 2-hydroxyethyl methacrylamide, N-vinylpyrrolidone (NVP), polyethyleneglycol monomethacrylate, methacrylic acid, acrylic acid and combinations thereof, with hydrophilic monomers comprising DMA being particularly preferred. Additional hydrophilic monomers may be present in amounts of about 0 to about 70 wt%, more preferably of about 5 and about 60 and most preferably of about 10 and 50 weight%, based upon the total weight of the reactive components.

### Crosslinkers

Suitable crosslinkers are compounds with two or more polymerizable functional groups. The crosslinker may be hydrophilic or hydrophobic and in some embodiments of the present invention mixtures of hydrophilic and hydrophobic crosslinkers have been found to provide silicone hydrogels with improved optical clarity (reduced haziness compared to a CSI Thin Lens®). Examples of suitable hydrophilic crosslinkers include compounds having two or more polymerizable functional groups, as well as hydrophilic functional groups such as polyether, amide or hydroxyl groups. Specific examples include TEGDMA (tetraethyleneglycol dimethacrylate), TrEGDMA (triethyleneglycol dimethacrylate), ethyleneglycol dimethacrylate (EGDMA), ethylenediamine dimethacrylamide, glycerol dimethacrylate and combinations thereof. Examples of suitable hydrophobic crosslinkers include multifunctional compatibilizing component, multifunctional polyether-polydimethylsiloxane block copolymers, combinations thereof and the like. Specific hydrophobic crosslinkers include acryloxypropyl terminated polydimethylsiloxane (n= 10 or 20) (acPDMS), hydroxylacrylate functionalized siloxane macromer, methacryloxypropyl terminated PDMS, butanediol dimethacrylate, divinyl benzene, 1,3-bis(3-methacryloxypropyl)tetrakis(trimethylsiloxy) disiloxane and mixtures thereof. Preferred crosslinkers include TEGDMA, EGDMA, acPDMS and combinations thereof. The amount of hydrophilic crosslinker used is generally about 0 to about 2 weight% and preferably from about 0.5 to about 2 weight % and the amount of hydrophobic crosslinker is about 0 to about 0 to about 5 weight % based upon the total weight of the reactive components, which can alternatively be referred to in mol% of about 0.01 to about 0.2 mmole/gm reactive components, preferably about 0.02 to about 0.1 and more preferably 0.03 to about 0.6 mmole/gm.

Increasing the level of crosslinker in the final polymer has been found to reduce the amount of haze. However, as crosslinker concentration increases above about 0.15 mmole/gm reactive components modulus increases above generally desired levels (greater than about 90 psi). Thus, in the present invention the crosslinker composition and amount is selected to

provide a crosslinker concentration in the reaction mixture of between about 1 and about 10 mmoles crosslinker per 100 grams of reactive components.

Additional components or additives, which are generally known in the art may also be included. Additives include but are not limited to ultra-violet  
5 absorbing compounds and monomer, reactive tints, antimicrobial compounds, pigments, photochromic, release agents, combinations thereof and the like.

### Diluents

The reactive components (compatibilizing component, hydrophilic  
10 polymer, oxygen permeable components, hydrophilic monomers, crosslinker(s) and other components) are mixed and reacted in the absence of water and optionally, in the presence of at least one diluent to form a reaction mixture. The type and amount of diluent used also effects the properties of the resultant polymer and article. The haze and wettability of the  
15 final article may be improved by selecting relatively hydrophobic diluents and/or decreasing the concentration of diluent used. As discussed above, increasing the hydrophobicity of the diluent may also allow poorly compatible components (as measured by the compatibility test) to be processed to form a compatible polymer and article. However, as the diluent becomes more  
20 hydrophobic, processing steps necessary to replace the diluent with water will require the use of solvents other than water. This may undesirably increase the complexity and cost of the manufacturing process. Thus, it is important to select a diluent which provides the desired compatibility to the components with the necessary level of processing convenience. Diluents useful in  
25 preparing the devices of this invention include ethers, esters, alkanes, alkyl halides, silanes, amides, alcohols and combinations thereof. Amides and alcohols are preferred diluents , and secondary and tertiary alcohols are most preferred alcohol diluents. Examples of ethers useful as diluents for this invention include tetrahydrofuran, tripropylene glycol methyl ether,  
30 dipropylene glycol methyl ether, ethylene glycol n-butyl ether, diethylene glycol n-butyl ether, diethylene glycol methyl ether, ethylene glycol phenyl ether, propylene glycol methyl ether, propylene glycol methyl ether acetate, dipropylene glycol methyl ether acetate, propylene glycol n-propyl ether, dipropylene glycol n-propyl ether, tripropylene glycol n-butyl ether, propylene

glycol n-butyl ether, dipropylene glycol n-butyl ether, tripropylene glycol n-butyl ether, propylene glycol phenyl ether dipropylene glycol dimethyl ether, polyethylene glycols, polypropylene glycols and mixtures thereof. Examples of esters useful for this invention include ethyl acetate, butyl acetate, amyl acetate, methyl lactate, ethyl lactate, i-propyl lactate. Examples of alkyl halides useful as diluents for this invention include methylene chloride. Examples of silanes useful as diluents for this invention include octamethylcyclotetrasiloxane.

Examples of alcohols useful as diluents for this invention include those having the formula

wherein Where R, R' and R'' are independently selected from H, a linear, branched or cyclic monovalent alkyl having 1 to 10 carbons which may optionally be substituted with one or more groups including halogens, ethers, esters, aryls, aminos, amides, alkenes, alkynes, carboxylic acids, alcohols, aldehydes, ketones or the like, or any two or all three of R, R' and R'' can together bond to form one or more cyclic structures, such as alkyl having 1 to 10 carbons which may also be substituted as just described, with the proviso that no more than one of R, R' or R'' is H.

It is preferred that R, R' and R'' are independently selected from H or unsubstituted linear, branched or cyclic alkyl groups having 1 to 7 carbons. It is more preferred that R, R', and R'' are independently selected from unsubstituted linear, branched or cyclic alkyl groups having 1 to 7 carbons. In certain embodiments, the preferred diluent has 4 or more, more preferably 5 or more total carbons, because the higher molecular weight diluents have lower volatility, and lower flammability. When one of the R, R' and R'' is H, the structure forms a secondary alcohol. When none of the R, R' and R'' are H,

the structure forms a tertiary alcohol. Tertiary alcohols are more preferred than secondary alcohols. The diluents are preferably inert and easily displaceable by water when the total number of carbons is five or less.

Examples of useful secondary alcohols include 2-butanol, 2-propanol, 5 menthol, cyclohexanol, cyclopentanol and exonorborneol, 2-pentanol, 3-pentanol, 2-hexanol, 3-hexanol, 3-methyl-2-butanol, 2-heptanol, 2-octanol, 2-nonanol, 2-decanol, 3-octanol, norborneol, and the like.

Examples of useful tertiary alcohols include tert-butanol, tert-amyl, alcohol, 2-methyl-2-pentanol, 2,3-dimethyl-2-butanol, 3-methyl-3-pentanol, 1- 10 methylcyclohexanol, 2-methyl-2-hexanol, 3,7-dimethyl-3-octanol, 1-chloro-2-methyl-2-propanol, 2-methyl-2-heptanol, 2-methyl-2-octanol, 2,2-methyl-2-nonanol, 2-methyl-2-decanol, 3-methyl-3-hexanol, 3-methyl-3-heptanol, 4-methyl-4-heptanol, 3-methyl-3-octanol, 4-methyl-4-octanol, 3-methyl-3-nonanol, 4-methyl-4-nonanol, 3-methyl-3-octanol, 3-ethyl-3-hexanol, 3-methyl- 15 3-heptanol, 4-ethyl-4-heptanol, 4-propyl-4-heptanol, 4-isopropyl-4-heptanol, 2,4-dimethyl-2-pentanol, 1-methylcyclopentanol, 1-ethylcyclopentanol, 1-ethylcyclopentanol, 3-hydroxy-3-methyl-1-butene, 4-hydroxy-4-methyl-1-cyclopentanol, 2-phenyl-2-propanol, 2-methoxy-2-methyl-2-propanol, 2,3,4-trimethyl-3-pentanol, 3,7-dimethyl-3-octanol, 2-phenyl-2-butanol, 2-methyl-1- 20 phenyl-2-propanol and 3-ethyl-3-pentanol, and the like.

A single alcohol or mixtures of two or more of the above-listed alcohols or two or more alcohols according to the structure above can be used as the diluent to make the polymer of this invention.

In certain embodiments, the preferred alcohol diluents are secondary and 25 tertiary alcohols having at least 4 carbons. The more preferred alcohol diluents include tert-butanol, tert-amyl alcohol, 2-butanol, 2-methyl-2-pentanol, 2,3-dimethyl-2-butanol, 3-methyl-3-pentanol, 3-ethyl-3-pentanol, 3,7-dimethyl-3-octanol.

Presently, the most preferred diluents are hexanol, heptanol, octanol, 30 nonanol, decanol, tert-butyl alcohol, 3-methyl-3-pentanol, isopropanol, tert amyl alcohol, ethyl lactate, methyl lactate, i-propyl lactate, 3,7-dimethyl-3-octanol, dimethyl formamide, dimethyl acetamide, dimethyl propionamide, N methyl pyrrolidinone and mixtures thereof. Additional diluents useful for this invention

are disclosed in US patent 6,020,445, which is incorporated herein by reference.

In one embodiment of the present invention the diluent is water soluble at processing conditions and readily washed out of the lens with water in a short period of time. Suitable water soluble diluents include 1-ethoxy-2-propanol, 1-methyl-2-propanol, t-amyl alcohol, tripropylene glycol methyl ether, isopropanol, 1-methyl-2-pyrrolidone, N,N-dimethylpropionamide, ethyl lactate, dipropylene glycol methyl ether, mixtures thereof and the like. The use of a water soluble diluent allows the post molding process to be conducted using water only or aqueous solutions which comprise water as a substantial component.

In one embodiment, the amount of diluent is generally less than about 50 weight % of the reaction mixture and preferably less than about 40 weight% and more preferably between about 10 and about 30 weight % based upon the total weight of the components of the reaction mixture.

The diluent may also comprise additional components such as release agents. Suitable release agents are water soluble and aid in lens deblocking

The polymerization initiators includes compounds such as lauryl peroxide, benzoyl peroxide, isopropyl percarbonate, azobisisobutyronitrile, and the like, that generate free radicals at moderately elevated temperatures, and photoinitiator systems such as aromatic alpha-hydroxy ketones, alkoxyoxybenzoin, acetophenones, acyl phosphine oxides, and a tertiary amine plus a diketone, mixtures thereof and the like. Illustrative examples of photoinitiators are 1-hydroxycyclohexyl phenyl ketone, 2-hydroxy-2-methyl-1-phenyl-propan-1-one, bis(2,6-dimethoxybenzoyl)-2,4,4-trimethylpentyl phosphine oxide (DMBAPO), bis(2,4,6-trimethylbenzoyl)-phenylphosphineoxide (Irgacure 819), 2,4,6-trimethylbenzoyldiphenyl phosphine oxide, 2,4,6-trimethylbenzoyl diphenylphosphine oxide, benzoin methyl ester, and a combination of camphorquinone and ethyl 4-(N,N-dimethylamino)benzoate. Commercially available visible light initiator systems include Irgacure 819, Irgacure 1700, Irgacure 1800, Irgacure 1850 (all from Ciba Specialty Chemicals) and Lucirin TPO initiator (available from BASF). Commercially available UV photoinitiators include Darocur 1173 and Darocur 2959 (Ciba Specialty Chemicals). The initiator is used in the reaction

mixture in effective amounts to initiate photopolymerization of the reaction mixture, e.g., from about 0.1 to about 2 parts by weight per 100 parts of reactive monomer. Polymerization of the reaction mixture can be initiated using the appropriate choice of heat or visible or ultraviolet light or other means depending on the polymerization initiator used. Alternatively, initiation can be conducted without a photoinitiator using, for example, e-beam. However, when a photoinitiator is used, the preferred initiator is a combination of 1-hydroxycyclohexyl phenyl ketone and bis(2,6-dimethoxybenzoyl)-2,4,4-trimethylpentyl phosphine oxide (DMBAPO), and the preferred method of polymerization initiation is visible light. The most preferred is bis(2,4,6-trimethylbenzoyl)-phenylphosphineoxide (Irgacure 819).

The preferred range of all silicone containing components (oxygen permeable components and compatibilizing components) is from about 5 to 99 weight percent, more preferably about 15 to 90 weight percent, and most preferably about 25 to about 80 weight percent, based upon the total weight of the reactive components. A preferred range of compatibilizing components is about 5 to about 90 weight percent, preferably about 10 to about 80, and most preferably about 20 to about 50 weight percent. A preferred range of hydrophilic monomer is from about 5 to about 80 weight percent, more preferably about 5 to about 60 weight percent, and most preferably about 10 to about 50 weight percent of the reactive components in the reaction mixture. A preferred range of high molecular weight hydrophilic polymer is about 1 to about 15 weight percent, more preferably about 3 to about 15 weight percent, and most preferably about 5 to about 12 weight percent. A preferred range of macromer is from about 5 to about 50 weight%, preferably from about 10 to about 50 weight % and more preferably from about 15 to about 45 weight %. All of the foregoing ranges are based upon the total weight of all reactive components.

A preferred range of diluent is from about 0 to about 70 weight percent, more preferably about 0 to about 50 weight percent, and still more preferably about 0 to about 40 weight percent and in some embodiments, most preferably between about 10 and about 30 weight percent based upon the weight of all components in the total reaction mixture. The amount of diluent

required varies depending on the nature and relative amounts of the reactive components.

The invention further comprises, consists and consists essentially of a silicone hydrogel, biomedical device, ophthalmic device and contact lenses of the formulations shown below:

| Wt% components |                    |                     |                   |                     |

CC is compatibilizing component

HMWHP is high molecular weight hydrophilic polymer

ASCM is additional siloxane containing monomer

HM is hydrophilic monomer

SCM is a siloxane containing macromer

Thus, the present invention includes silicone hydrogel, biomedical device, ophthalmic device and contact lenses having each of the composition listed in the table, which describes 261 possible compositional ranges. Each of the ranges listed above is prefaced by the word "about". The foregoing range combinations are presented with the proviso that the listed components, and any additional components add up to 100 weight%.

In a preferred embodiment, the reactive components comprise about 28 wt.% SiGMA; about 31 wt.% 800-1000 MW monomethacryloxypropyl terminated mono-n-butyl terminated polydimethylsiloxane, "mPDMS", about 24 wt.% N,N-dimethylacrylamide, "DMA", about 6 wt.% 2-hydroxyethyl methacrylate, "HEMA", about 1.5 wt% tetraethyleneglycoldimethacrylate, "TEGDMA", about 7 wt.% polyvinylpyrrolidone, "K-90 PVP"; with the balance comprising minor amounts of additives and photoinitiators. The polymerization

is most preferably conducted in the presence of about 23% (weight % of the combined monomers and diluent blend) 3,7-dimethyl-3-octanol diluent.

In a second preferred embodiment the reactive components comprise about 30 wt.% SiGMA, about 23 wt.% mPDMS, about 31 wt.% DMA, about 0.5  
5 to about 1 wt.% ethyleneglycoldimethacrylate, "EGDMA", about 6 wt.% K-90 PVP; and about 7.5 wt.% HEMA, with the balance comprising minor amounts of additives and photoinitiators. The polymerization is most preferably conducted in the presence of tert-amyl-alcohol as a diluent comprising about 29 weight percent of the reaction mixture. The diluent may also comprise  
10 about 11 weight % low molecular weight PVP (less than about 5,000 and preferably less than about 3,000  $M_n$ ).

In a third preferred embodiment, the reactive components comprise about 11-18 wt % macromer (the GTP reaction product of about 24 wt.% HEMA; about 3wt% MMA; about 33wt.%  
15 methacryloxypropyltris(trimethylsiloxy)silane and about 32wt.% mono-methacryloxypropyl terminated mono-butyl terminated polydimethylsiloxane functionalized with 8 wt % 3-isopropenyl-  $\alpha,\alpha$ -dimethylbenzyl isocyanate); about 18-30 wt.% mPDMS, about 2-10 wt% acPDMS, about 27-33 wt.% DMA, about 13-15 wt.% TRIS, about 2-5 wt.% HEMA, and about 5-7 wt.% K-  
20 90 PVP; with the balance comprising minor amounts of additives and photoinitiators. The polymerization is most preferably conducted in the presence of 25-30% (weight % of the combined monomers and diluent blend) a diluent comprising 3,7-dimethyl-3-octanol.

In a fourth preferred embodiment, the reactive components comprise  
25 between about 15 to about 40 wt.% macromer (formed from perfluoroether having a mean molecular weight of about 1030 g/mol and  $\alpha$ ,  $\omega$ -hydroxypropyl-terminated polydimethylsiloxane having a mean molecular weight of about 2000 g/mol, isophorone diisocyanate and isocyanatoethyl methacrylate); about 40 to about 52% SiGMA, about 0 to about 5 wt% 3-  
30 tris(trimethylsiloxy)silylpropyl methacrylate, "TRIS", about 22 to about 32 wt.% DMA, about 3 about 8 wt% K-90 PVP with the balance comprising minor amounts of additives and photoinitiators. The polymerization is most preferably conducted in the presence of about 15 to about 40, and preferably

between about 20 and about 40% (weight % of the combined monomers and diluent blend), diluent, which may, in some embodiments preferably be ethanol, 3,7-dimethyl-3-octanol.

## 5 Processing

The biomedical devices of the invention are prepared by mixing the high molecular weight hydrophilic polymer, the compatibilizing component, plus one or more of the following: the oxygen permeability enhancing component, the hydrophilic monomers, the additives ("reactive components"),  
10 and the diluents ("reaction mixture"), with a polymerization initiator and curing by appropriate conditions to form a product that can be subsequently formed into the appropriate shape by lathing, cutting and the like. Alternatively, the reaction mixture may be placed in a mold and subsequently cured into the appropriate article.

15 Various processes are known for curing the reaction mixture in the production of contact lenses, including spincasting and static casting. Spincasting methods are disclosed in U.S. Pat. Nos. 3,408,429 and 3,660,545, and static casting methods are disclosed in U.S. Pat. Nos. 4,113,224 and 4,197,266. The preferred method for producing contact lenses  
20 comprising the polymer of this invention is by the direct molding of the silicone hydrogels, which is economical, and enables precise control over the final shape of the hydrated lens. For this method, the reaction mixture is placed in a mold having the shape of the final desired silicone hydrogel, i.e., water-swollen polymer, and the reaction mixture is subjected to conditions whereby  
25 the monomers polymerize, to thereby produce a polymer/diluent mixture in the shape of the final desired product. Then, this polymer/diluent mixture is treated with a solvent to remove the diluent and ultimately replace it with water, producing a silicone hydrogel having a final size and shape which are quite similar to the size and shape of the original molded polymer/diluent  
30 article. This method can be used to form contact lenses and is further described in U.S. Pat. Nos. 4,495,313; 4,680,336; 4,889,664; and 5,039,459, incorporated herein by reference.

Curing

Yet another feature of the present invention is a process for curing silicone hydrogel formulations to provide enhanced wettability. It has been found that the gel time for a silicone hydrogel may be used to select cure conditions which provide a wettable ophthalmic device, and specifically a contact lens. The gel time is the time at which a crosslinked polymer network is formed, resulting in the viscosity of the curing reaction mixture approaching infinity and the reaction mixture becoming non-fluid. The gel point occurs at a specific degree of conversion, independent of reaction conditions, and therefore can be used as an indicator of the rate of the reaction. It has been found that, for a given reaction mixture, the gel time may be used to determine cure conditions which impart desirable wettability. Thus, in a process of the present invention, the reaction mixture is cured at or above a gel time that provides improved wettability, or more preferably sufficient wettability for the resulting device to be used without a hydrophilic coating or surface treatment ("minimum gel time"). Preferably improved wettability is a decrease in advancing dynamic contact angle of at least 10% compared to formulation with no high molecular weight polymer. Longer gel times are preferred as they provide improved wettability and increased processing flexibility.

Gel times will vary for different silicone hydrogel formulations. Cure conditions also effect gel time. For example the concentration of crosslinker will impact gel time, increasing crosslinker concentrations decreases gel time. Increasing the intensity of the radiation (for photopolymerization) or temperature (for thermal polymerization), the efficiency of initiation (either by selecting a more efficient initiator or irradiation source, or an initiator which absorbs more strongly in the selected irradiation range) will also decrease gel time. Temperature and diluent type and concentration also effect gel time in ways understood by those of skill in the art.

The minimum gel time may be determined by selecting a given formulation, varying one of the above factors and measuring the gel time and contact angles. The minimum gel time is the point above which the resulting lens is generally wettable. Below the minimum gel time the lens is generally not wettable. For a contact lens "generally wettable" is a lens which displays

an advancing dynamic contact angle of less than about 70 and preferably less than about 60° or a contact lens which displays a tear film break up time equal to or better than an ACUVUE® lens. Thus, those of skill in the art will appreciate that minimum gel point as defined herein may be a range, taking  
5 into consideration statistical experimental variability.

In certain embodiments using visible light irradiation minimum gel times of at least about 30, preferably greater than about 35, and more preferably greater than about 40 seconds have been found to be advantageous.

10 Curing may be conducted using heat, ionizing or actinic radiation, for example electron beams, Xrays, UV or visible light, ie. electromagnetic radiation or particle radiation having a wavelength in the range of from about 150 to about 800 nm. Preferable radiation sources include UV or visible light having a wavelength of about 250 to about 700 nm. Suitable radiation  
15 sources include UV lamps, fluorescent lamps, incandescent lamps, mercury vapor lamps, and sunlight. In embodiments where a UV absorbing compound is included in the reaction mixture (for example, as a UV block or photochromic) curing is conducting by means other than UV irradiation (such as by visible light or heat). In a preferred embodiment the radiation source is  
20 selected from UVA (about 315 – about 400 nm), UVB (about 280-about 315) or visible light (about 400 –about 450 nm). In another preferred embodiment, the reaction mixture includes a UV absorbing compound, is cured using visible light. In many embodiments it will be useful to cure the reaction mixture at low intensity to achieve the desired minimum gel time. As used  
25 herein the term “low intensity” means those between about 0.1 mW/cm<sup>2</sup> to about 6 mW/cm<sup>2</sup> and preferably between about 1 mW/cm<sup>2</sup> and 3 mW/cm<sup>2</sup>. The cure time is long, generally more than about 1 minute and preferably between about 1 and about 60 minutes and still more preferably between about 1 and about 30 minutes This slow, low intensity cure is one way to  
30 provide the desired minimum gel times and produce ophthalmic devices which display good wettability.

Initiator concentration also effects gel time. Accordingly, in some embodiments it is preferred to have relatively low amounts of photoinitiator, generally 1% or less and preferably 0.5% or less.

The temperature at which the reaction mixture is cured is also  
5 important. As the temperature is increased above ambient the haze of the resulting polymer decreases. Temperatures effective to reduce haze include temperatures at which the haze for the resulting lens is decreased by at least about 20% as compared to a lens of the same composition made at 25°C. Thus, suitable cure temperatures include those greater than about 25°C,  
10 preferably those between about 25°C and 70°C and more preferably those between about 40°C and 70°C. The precise set of cure conditions (temperature, intensity and time) will depend upon the components of lens material selected and, with reference to the teaching herein, are within the skill of one of ordinary skill in the art to determine. Cure may be conducted in  
15 one or a multiplicity of cure zones.

The cure conditions must be sufficient to form a polymer network from the reaction mixture. The resulting polymer network is swollen with the diluent and has the form of the mold cavity.

## 20 Deblocking

After the lenses have been cured they must be removed from the mold. Unfortunately, the silicone components used in the lens formulation render the finished lenses "sticky" and difficult to release from the lens molds. Lenses can be deblocked (removed from the mold half or tool supporting the lens)  
25 using a solvent, such as an organic solvent. However, in one embodiment of the present invention at least one low molecular weight hydrophilic polymer is added to the reaction mixture, the reaction mixture is formed into the desired article, cured and deblocked in water or an aqueous solution comprising, consisting essentially of and consisting of a small amount of surfactant. The  
30 low molecular weight hydrophilic polymer can be any polymer having a structure as defined for a high molecular weight polymer, but with a molecular weight such that the low molecular weight hydrophilic polymer extracts or leaches from the lens under deblocking conditions to assist in lens release

from the mold. Suitable molecular weights include those less than about 40,000 Daltons and preferably less than about 20,000 Daltons. Those of skill in the art will appreciate that the foregoing molecular weights are averages, and that some amount of material having a molecular weight higher than the  
5 given averages may be suitable, so long as the average molecular weight is within the specified range. Preferably the low molecular weight polymer is selected from water soluble polyamides, lactams and polyethylene glycols, and mixtures thereof and more preferably poly-vinylpyrrolidone, polyethylene glycols, poly 2 ethyl-2-oxazoline (available from Plymer Chemistry  
10 Innovations, Tuscon, AZ), polymethacrylic acid, poly(1-lactic acid), polycaprolactam, polycaprolactone, polycaprolactone diol, polyvinyl alcohol, polyhema, polyacrylic acid, poly(1-glycerol methacrylate), poly(2-ethyl-2-oxazoline), poly(2-hydroxypropyl methacrylate), poly(2-vinylpyridine N-oxide), polyacrylamide, polymethacrylamide and the like.

15 The low molecular weight hydrophilic polymer may be used in amounts up to about 20 wt.% and preferably in amounts between about 5 and about 20 wt% of the reactive components.

Suitable surfactants include non-ionic surfactants including betaines, amine oxides, combinations thereof and the like . Examples of suitable  
20 surfactants include TWEEN® (ICI), DOE 120 (Amerchol/Union Carbide and the like. The surfactants may be used in amounts up to about 10,000 ppm, preferably between about 25 ppm and about 1500 ppm and more preferably between about 100 and about 1200 ppm.

Suitable release agents are low molecular weight, and include 1-  
25 methyl-4-piperidone, 3-morpholino-1,2-propanediol, tetrahydro-2H-pyran-4-ol, glycerol formal, ethyl-4-oxo-1-piperidine carboxylate, 1,3-dimethyl-3,4,5,6-tetrahydro-2(1H)-pyrimidinone and 1-(2-hydroxyethyl)-2-pyrrolidone

Lenses made from reaction mixtures without low molecular weight hydrophilic polymer may be deblocked in an aqueous solution comprising at  
30 least one organic solvent. Suitable organic solvents are hydrophobic, but miscible with water. Alcohols, ethers and the like are suitable, more specifically primary alcohols and more specifically isopropyl alcohol, DPMA, TPM, DPM, methanol, ethanol, propanol and mixtures thereof being suitable examples.

Suitable deblocking temperatures range from about ambient to about 100°C, preferably between about 70°C and 95°C, with higher temperatures providing quicker deblocking times. Agitation, such as by sonication, may also be used to decrease deblocking times. Other means known in the art, such as vacuum nozzles may also be used to remove the lenses from the molds.

#### Diluent replacement/hydration

Typically after curing the reaction mixture, the resulting polymer is treated with a solvent to remove the diluent (if used), unreacted components, byproducts, and the like and hydrate the polymer to form the hydrogel. Alternatively, depending on the solubility characteristics of the hydrogel's components, the solvent initially used can be an organic liquid such as ethanol, methanol, isopropanol, TPM, DPM, PEGs, PPGs, glycerol, mixtures thereof, or a mixture of one or more such organic liquids with water, followed by extraction with pure water (or physiological saline). The organic liquid may also be used as a "pre-soak". After demolding, lenses may be briefly soaked (times up to about 30 minutes, preferably between about 5 and about 30 minutes) in the organic liquid or a mixture of organic liquid and water. After the pre-soak, the lens may be further hydrated using aqueous extraction solvents.

In some embodiments, the preferred process uses an extraction solvent that is predominately water, preferably greater than 90% water, more preferably greater than 97% water. Other components may include salts such as sodium chloride, sodium borate boric acid, DPM, TPM, ethanol or isopropanol. Lenses are generally released from the molds into this extraction solvent, optionally with stirring or a continuous flow of the extraction solvent over the lenses. This process can be conducted at temperatures from 2 to 121°C, preferably from 20 to 98°C. The process can be conducted at elevated pressures, particularly when using temperatures in excess of 100°C, but is more typically conducted at ambient pressures. It is possible to deblock the lenses into one solution (for example containing some release aid) and then transfer them into another (for example the final packing solution),

although it may also be possible to deblock the lenses into the same solution in which they are packaged. The treatment of lenses with this extraction solvent may be conducted for a period of from about 30 seconds to about 3 days, preferably between about 5 and about 30 minutes. The selected

5 hydration solution may additionally comprise small amounts of additives such as surfactants and/or release aids. Suitable surfactants include non-ionic surfactants, such as betaines and amine oxides. Specific surfactants include TWEEN 80 (available from Amerchol), DOE 120 (available from Union Carbide), Pluronics, methyl cellulose, mixtures thereof and the like and may

10 be added in amounts between about 0.01 weight% and about 5% based upon total weight of hydration solution used.

In one embodiment the lenses may be hydrated using a "step down" method, where the solvent is replaced in steps over the hydration process. Suitable step down processes have at least two, at least three and in some

15 embodiments at least four steps, where a percentage of the solvent is replaced with water.

The silicone hydrogels after hydration of the polymers preferably comprise about 10 to about 60 weight percent water, more preferably about 20 to about 55 weight percent water, and most preferably about 25 to about

20 50 weight percent water of the total weight of the silicone hydrogel. Further details on the methods of producing silicone hydrogel contact lenses are disclosed in U.S. Patents 4,495,313; 4,680,336; 4,889,664; and 5,039,459, which are hereby incorporated by reference.

The cured biomedical device of the present invention displays excellent

25 resistance to fouling in vivo, even without a coating. When the biomedical device is an ophthalmic device, resistance to biofouling may be measured by measuring the amount of surface deposits on the lens during the wear period, often referred to as "lipid deposits".

Lens surface deposits are measured as follows: Lenses were put on

30 human eyes and evaluated after 30 minutes and one week of wear using a slit lamp. During the evaluation the patient is asked to blink several times and the lenses are manually "pushed" in order to differentiate between deposits and back surface trapped debris. Front and back surface deposits are graded as being discrete (i.e. jelly bumps) or filmy. Front surface deposits give a bright

reflection while back surface deposits do not. Deposits are differentiated from back surface trapped debris during a blink or a push-up test. The deposits will move while the back surface trapped debris will remain still. The deposits are graded into five categories based upon the percentage of the lens surface which is effected: none (< about 1%), slight (about 1 to about 5%), mild (about 6% to about 15%), moderate (about 16% to about 25%) and severe (greater than about 25%). A 10% difference between the categories is considered clinically significant.

The ophthalmic devices of the present invention also display low haze, good wettability and modulus.

Haze is measured by placing test lenses in saline in a clear cell above a black background, illuminating from below with a fiber optic lamp at an angle 66° normal to the lens cell, and capturing an image of the lens from above with a video camera. The background-subtracted scattered light image was quantitatively analyzed, by integrating over the central 10 mm of the lens, and then compared to a -1.00 diopter CSI Thin Lens®, which is arbitrarily set at a haze value of 100, with no lens set as a haze value of 0.

Wettability is measured by measuring the contact angle or DCA, typically with borate buffered saline, using a Wilhelmy balance at 23°C. The wetting force between the lens surface and borate buffered saline is measured using a Wilhelmy microbalance while the sample is being immersed into or pulled out of the saline. The following equation is used

$$F = 2\gamma p \cos\theta \quad \text{or} \quad \theta = \cos^{-1}(F/2\gamma p)$$

where F is the wetting force,  $\gamma$  is the surface tension of the probe liquid, p is the perimeter of the sample at the meniscus and  $\theta$  is the contact angle. Typically, two contact angles are obtained from a dynamic wetting experiment – advancing contact angle and receding contact angle. Advancing contact angle is obtained from the portion of the wetting experiment where the sample is being immersed into the probe liquid. At least 4 lenses of each composition are measured and the values reported herein.

However, DCA is not always a good predictor of wettability on eye. The pre-lens tear film non-invasive break-up time (PLTF-NIBUT) is one

measure of in vivo or "clinical" lens wettability. The PLTF-NIBUT is measured using a slit lamp and a circular fluorescent tearscope for noninvasive viewing of the tearfilm (Keeler Tearscope Plus). The time elapsed between the eye opening after a blink and the appearance of the first dark spot within the tear film on the front surface of a contact lens is recorded as PLTF-NIBUT. The PLTF-NIBUT was measured 30-minutes after the lenses were placed on eye and after one week. Three measurements were taken at each time interval and were averaged into one reading. The PLTF-NIBUT was measured on both eyes, beginning with the right eye and then the left eye.

Movement is measured using the "push up" test. The patient's eyes are in the primary gaze position. The push-up test is a gentle digital push of the lens upwards using the lower lid. The resistance of the lens to upward movement is judged and graded according to the following scale: 1 (excessive, unacceptable movement), 2 (moderate, but acceptable movement), 3 (optimal movement), 4 (minimal, but acceptable movement), 5 (insufficient, unacceptable movement).

The lenses of the present invention display moduli of at least about 30 psi, preferably between about 30 and about 90 psi, and more preferably between about 40 and about 70 psi. Modulus is measured by using the crosshead of a constant rate of movement type tensile testing machine equipped with a load cell that is lowered to the initial gauge height. A suitable testing machine includes an Instron model 1122. A dog-bone shaped sample having a 0.522 inch length, 0.276 inch "ear" width and 0.213 inch "neck" width is loaded into the grips and elongated at a constant rate of strain of 2 in/min. until it breaks. The initial gauge length of the sample ( $L_0$ ) and sample length at break ( $L_f$ ) are measured. Twelve specimens of each composition are measured and the average is reported. Tensile modulus is measured at the initial linear portion of the stress/strain curve.

The contact lenses prepared by this invention have  $O_2$  Dk values between about 40 and about 300 barrer, determined by the polarographic method. Lenses are positioned on the sensor then covered on the upper side with a mesh support. The lens is exposed to an atmosphere of humidified 2.1%  $O_2$ . The oxygen that diffuses through the lens is measured using a polarographic oxygen sensor consisting of a 4 mm diameter gold cathode and

a silver ring anode. The reference values are those measured on commercially available contact lenses using this method. Balafilcon A lenses available from Bausch & Lomb give a measurement of approx. 79 barrer. Etafilcon lenses give a measurement of 20 to 25 barrer. (1 barrer =  $10^{-10}$  (cm<sup>3</sup> of gas x cm<sup>2</sup>)/(cm<sup>3</sup> of polymer x s x cm Hg).

Gel time was measured using the following method. The photo-polymerization reaction was monitored with an ATS StressTech rheometer equipped with a photo-curing accessory, which consists of a temperature-controlled cell with a quartz lower plate and an aluminum upper plate, and a radiation delivery system equipped with a bandpass filter. The radiation, which originates at a Novacure mercury arc lamp equipped with an iris and computer-controlled shutter, was delivered to the quartz plate in the rheometer via a liquid light guide. The filter was a 420 nm (20 nm FWHM) bandpass filter, which simulates the light emitted from a TL03 bulb. The intensity of the radiation, measured at the surface of the quartz window with an IL1400A radiometer, was controlled to  $\pm 0.02$  mW/cm<sup>2</sup> with an iris. The temperature was controlled at  $45 \pm 0.1^\circ\text{C}$ . After approximately 1 mL of the de-gassed reactive mixture was placed on the lower plate of the rheometer, the 25 mm diameter upper plate was lowered to  $0.500 \pm 0.001$  mm above the lower plate, where it was held until after the reaction reached the gel point. The sample was allowed to reach thermal equilibrium (~4 minutes, determined by the leveling-off of the steady shear viscosity) before the lamp shutter was opened and the reaction begun. During this time while the sample was reaching thermal equilibrium, the sample chamber was purged with nitrogen gas at a rate of 400 sccm. During the reaction the rheometer continuously monitored the strain resulting from an applied dynamic stress (fast oscillation mode), where time segments of less than a complete cycle were used to calculate the strain at the applied programmable stress. The computer calculated the dynamic shear modulus ( $G'$ ), loss modulus ( $G''$ ), and viscosity ( $\eta^*$ ), as a function of exposure time. As the reaction proceeded the shear modulus increased from  $<1$  Pa to  $>0.1$  MPa, and  $\tan \delta$  ( $=G''/G'$ ) dropped from near infinity to less than 1. For measurements made herein the gel time is the time at which  $\tan \delta$  equals 1, (the crossover point when  $G'=G''$ ). At the time

that G' reaches 100 Pa (shortly after the gel point), the restriction on the upper plate was removed so that the gap between the upper and lower plates can change as the reactive monomer mix shrinks during cure.

It will be appreciated that all of the tests specified above have a certain amount of inherent test error. Accordingly, results reported herein are not to be taken as absolute numbers, but numerical ranges based upon the precision of the particular test.

In order to illustrate the invention the following examples are included. These examples do not limit the invention. They are meant only to suggest a method of practicing the invention. Those knowledgeable in contact lenses as well as other specialties may find other methods of practicing the invention. However, those methods are deemed to be within the scope of this invention.

### EXAMPLES

The following abbreviations are used in the examples below:

|           |                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------|
| SiGMA     | 2-propenoic acid, 2-methyl-2-hydroxy-3-[3-[1,3,3,3-tetramethyl-1-[trimethylsilyl]oxy]disiloxanyl]propoxy]propyl ester    |
| DMA       | N,N-dimethylacrylamide                                                                                                   |
| HEMA      | 2-hydroxyethyl methacrylate                                                                                              |
| mPDMS     | 800-1000 MW ( $M_n$ ) monomethacryloxypropyl terminated mono-n-butyl terminated polydimethylsiloxane                     |

|    | IPL       | isopropyl lactate                                                   |
|    | CGI 819   | 2,4,6-trimethylbenzylidiphenyl phosphine oxide                      |

Throughout the Examples intensity is measured using an IL 1400A  
15 radiometer, using an XRL 140A sensor.

#### Examples 1-10

The reaction components and diluent (D30) listed in Table 1 were  
mixed together with stirring or rolling for at least about 3 hours at 23°C, until  
20 all components were dissolved. The reactive components are reported as  
weight percent of all reactive components and the diluent is weight percent of  
reaction mixture. The reaction mixture was placed into thermoplastic contact  
lens molds (made from Topas® copolymers of ethylene and norbornene  
obtained from Ticona Polymers), and irradiated using Philips TL 20W/03T  
25 fluorescent bulbs at 45°C for about 20 minutes N<sub>2</sub>. The molds were opened  
and lenses were extracted into a 50:50 (wt) solution of IPA and H<sub>2</sub>O, and  
soaked in IPA at ambient temperature for about 15 hours to remove residual  
diluent and monomers, placed into deionized H<sub>2</sub>O for about 30 minutes, then  
equilibrated in borate buffered saline for at least about 24 hours and  
30 autoclaved at 122°C for 30 minutes. The properties of the resulting lenses  
are shown in Table 1.

Table 1

| EX. #                            | 1    | 2   | 3    | 4    | 5   | 6   | 7   | 8    | 9   | 10  |

1. Equilibrium water content

2. Dynamic contact angle, measured with physiological borate-buffered saline using a Wilhelmy balance.

5 3. Oxygen permeability, edge corrected, in Barrers.

The results of Examples 1-10 show that the reaction mixture components and their amounts may be varied substantially, while still providing uncoated lenses having an excellent balance of mechanical properties and wettability. The contact angle (DCA) of Example 9 may be too high to form a lens that would be clinically wettable, and the modulus may be lower than desired to provide a mechanically robust lens. Example 9 contained the lowest concentration of SiGMA (20%). Because the SiGMA

10

had been reduced, less PVP could be added to the formulation and still provide a compatible reaction mixture. Thus, these examples show that SiGMA is effective in compatibilizing PVP and that when sufficient SiGMA and PVP are present lenses with desirable wettability and other mechanical properties can be made without any form of surface modification.

#### Example 11

Lenses having the formulation of Example 1 were remade, without controlling cure intensity. The mechanical properties are reported in Table 2, below. These lenses were clinically evaluated using ACUVUE® 2 lenses as controls. The test lenses were worn in one eye and an ACUVUE® 2 lens was worn on the contralateral eye. The lenses were worn by 6 patients in a daily wear mode (nightly removal) for a period of one week. At one week the PLTF-NIBUT was 3.6 ( $\pm 3.0$ ) seconds compared to 5.8 ( $\pm 2.5$ ) seconds for ACUVUE® 2 lenses. The front surface deposition was graded none to slight for 50% of the test lenses and 100% for the control lenses. The movement was acceptable for both test and control lenses.

#### Example 12

Example 11 was repeated except that the cure intensity was reduced to 1.0 mW/cm<sup>2</sup>. The mechanical properties are reported in Table 2, below. These lenses were clinically evaluated using ACUVUE® 2 lenses as controls. The test lenses were worn by 15 patients in a daily wear mode (nightly removal), in one eye for a period of one week and an ACUVUE® 2 lens was worn in the contralateral eye. At one week the PLTF-NIBUT was 8.2 ( $\pm 1.7$ ) seconds compared to 6.9 ( $\pm 1.5$ ) seconds for ACUVUE® 2 lenses. The front surface deposition was graded none to slight for all of the patients for both test and control lenses. The movement was acceptable for both test and control lenses.

**Table 2**

| Ex.#          | 1  | 11 | 12 |
|---------------|----|----|----|
| %EWC          | 36 | 36 | 36 |
| Modulus (psi) | 68 | 74 | 87 |

|            |     |     |     |
|------------|-----|-----|-----|
| Elongation | 301 | 315 | 223 |
| DCA        | 62  | 77  | 56  |
| Dk         | 103 | 127 | 102 |

Generally the mechanical properties for Examples 1, 11 and 12 are consistent results for multiple runs of the same material. However, the clinical results for Examples 11 (uncontrolled cure intensity) and 12 (low, controlled cure intensity) are substantially different. The on eye wettability after one week of wear for Example 11 (measured by PLTF-NIBUT) was worse than the ACUVUE® 2 lenses (3.6 v. 5.8) and half the lenses had more than slight surface depositions. The Example 12 lenses (controlled, low intensity cure) displayed significantly improved on-eye wettability, which was measurably better than ACUVUE® 2 lenses (8.2 v. 6.9) and no surface depositions. Thus, using a low, controlled cure provides an uncoated lens having on-eye wettability which is as good as, and in some cases better than conventional hydrogel lenses.

#### Examples 13-17

Reaction mixtures described in Table 3 and containing low or no compatibilizing component (in these Examples SiGMA) were mixed with constant stirring at room temperature for 16 hours. Even after 16 hours each of the reaction mixtures remained cloudy and some contained precipitates. Accordingly, these reaction mixtures could not be used to produce lenses.

**Table 3**

| Ex. #       | 13  | 14  | 15   | 16  | 17  |
|-------------|-----|-----|------|-----|-----|
| Composition |     |     |      |     |     |
| SiGMA       | 0   | 0   | 0    | 10  | 20  |
| PVP (K90)   | 12  | 12  | 10   | 8.0 | 8.0 |
| DMA         | 10  | 10  | 8.3  | 19  | 19  |
| MPDMS       | 37  | 37  | 30.8 | 35  | 28  |
| TRIS        | 14  | 14  | 11.7 | 17  | 14  |
| HEMA        | 25  | 25  | 37.5 | 8.0 | 8.0 |
| Norbloc     | 0   | 0   | 0    | 0   | 0   |
| CGI 1850    | 0   | 0   | 0    | 0   | 0   |
| TEGDMA      | 1.0 | 1.0 | 0.83 | 2.0 | 2.0 |
| TrEGDMA     | 0   | 0   | 0    | 0   | 0   |
| Blue HEMA   | 0   | 0   | 0    | 0   | 0   |

|              |     |     |      |     |     |
|--------------|-----|-----|------|-----|-----|
| mPDMS-OH     | 0   | 0   | 0    | 0   | 0   |
| Darocur 1173 | 1.0 | 1.0 | 0.83 | 1.0 | 1.0 |
|              |     |     |      |     |     |
| D30 %        | 23  | 31  | 31   | 27  | 27  |

Examples 13 through 15 show that reaction mixtures without any compatibilizing component (SiGMA or mPDMS-OH) are incompatible, and not suitable for making contact lenses. Examples 16 and 17 show that concentrations of compatibilizing component less than about 20 weight% are insufficient to compatibilize significant amounts of high molecular weight PVP. However, comparing Example 17 to Example 9, lesser amounts of high molecular weight PVP (3 weight %) can be included and still form a compatible reaction mixture.

#### Examples 18-26

A solution of 1.00 gram of D3O, 1.00 gram of mPDMS and 1.00 gram of TRIS was placed in a glass vial (Ex. 18). As the blend was rapidly stirred at about 20 to 23 °C with a magnetic stir bar, a solution of 12 parts (wt) PVP (K90) and 60 parts DMA was added dropwise until the solution remained cloudy after 3 minutes of stirring. The mass of the added DMA/PVP blend was determined in grams and reported as the "monomer compatibility index". This test was repeated using SiGMA (Ex. 19), MBM (Ex. 20), MPD (Ex. 21), acPDMS, where n=10 (Ex. 22), acPDMS where n=20 (Ex. 23), iSiGMA-3Me (Ex. 24) and TRIS2-HOEOP2 (Ex. 25) as test silicone monomers in place of TRIS.

**Table 4**

| Ex. # | Test silicone-containing monomer | Monomer compatibility index | Si:OH |
|-------|----------------------------------|-----------------------------|-------|
| 18    | SiGMA                            | 1.8                         | 3:1   |
| 19    | TRIS                             | 0.07                        | 4:0   |
| 20    | MBM                              | 0.09                        | 3:0   |
| 21    | MPD                              | 0.05                        | 2:0   |
| 22    | acPDMS (n=10)*                   | 1.9                         | 11:2  |

|    |                |      |       |
|----|----------------|------|-------|
| 23 | acPDMS (n=20)* | 1    | 21:2  |
| 24 | iSiMAA-3Me     | 0.15 | 4:0   |
| 25 | TRIS2-HOEOP2   | 0.11 | 3:2   |
| 26 | MPDMS-OH       | 0.64 | ~11:2 |

Doug – should we try mPDMS-OH and see what that number is?

Structures for acPDMS, iSiGMA-3Me and TRIS2-HOEOP2 are shown below.

5 acPDMS (n averages 10 or 20):

10 TRIS2-HOEOP2

iSiMAA3-Me

The results, shown in Table 4, show that SiGMA, acPDMS (where n= 10 and 20) and mPDMS-OH more readily incorporate into a blend of a diluent, another silicone containing monomer, a hydrophilic monomer, and an high molecular weight polymer (PVP) than alternative silicone-containing monomers. Thus, compatibilizing silicone containing monomers having a compatibility index of greater than about 0.5 are useful for compatibilizing high molecular weight hydrophilic polymers like PVP.

Example 27 -35

Lenses were made using the reaction mixture formulation of Example 1. The plastic contact lens molds (made from Topas® copolymers of ethylene and norbornene obtained from Ticona Polymers) were stored overnight in nitrogen (<0.5% O<sub>2</sub>) before use. Each mold was dosed with 75 µl reaction mixture. Molds were closed and lenses photocured using the times and cure intensities indicated in Table 5. Lenses were formed by irradiation of the monomer mix using visible light fluorescent bulbs, curing at 45°C. The intensity was varied by using a variable balast or light filters, in two steps of varied intensity and cure time. The step 2 time was selected to provide the same total irradiation energy (about 830 mJ/cm<sup>2</sup>) for each sample.

The finished lenses were demolded use a 60:40 mixture of isopropyl alcohol/DI water. The lenses were transferred to a jar containing 300 g 100% isopropyl alcohol (IPA). The IPA was replaced every 2 hours for 10 hours. At the end of about 10 hours, 50% of the IPA was removed and replaced with DI water and the jar was rolled for 20 minutes. After 20 minutes, 50% of the IPA was removed and replaced with DI water and the jar was rolled for another 20 minutes. The lenses were transferred to packing solution, rolled for 20 minutes and then tested.

**Table 5**

| Ex.# | Step 1 intensity (mW/cm <sup>2</sup> ) | Step 1 time (min:sec) | Step 2 intensity (mW/cm <sup>2</sup> ) | Step 2 time (min:sec) | Advancing Contact Angle |

| 33   | 2.4                                    | 2:52                  | 5.5                                    | 1:28                  | 62 ± 6                  |
| 34   | 2.4                                    | 4:36                  | 5.5                                    | 0:35                  | 76 ± 9                  |
| 35   | 2.4                                    | 1:09                  | 5.5                                    | 0:35                  | 78 ± 6                  |

The contact angles for Examples 27 through 232 are not significantly different, indicating that step 1 cure intensities of less than about 2 mW/cm<sup>2</sup> provide improved wettability for this lens formulation regardless of

the step 1 cure time. However, those of skill in the art will appreciate that shorter step 1 cure times (such as those used in Examples 28 and 31) allow for shorter overall cure cycles. Moreover, it should be noted that even though the contact angles for Examples 33 through 35 are measurably higher than those of Examples 27-32, the lenses of Examples 33-35 may still provide desirable on eye wettability.

#### Examples 36 - 41

The reaction components of Example 1, were blended with either 25% or 40% D3O as diluent in accordance with the procedure of Example 1. The resultant reaction mixtures were charged into plastic contact lens molds (made from Topas® copolymers of ethylene and norbornene obtained from Ticona Polymers) and cured in a glove box under a nitrogen atmosphere, at about 2.5 mW/cm<sup>2</sup> intensity, about 30 minutes and the temperatures shown in Table 6, below. The lenses were removed from the molds, hydrated and autoclaved as describe in Example 1. After hydration the haze values of the lenses were determined. The results shown in Table 6 show that the degree of haziness was reduced at the higher temperatures. The results also show that as the concentration of diluent decreases the haze also decreases.

**Table 6**

| Ex. # | %D3O | Temp. (°C) | % haze   | DCA(°) |
|-------|------|------------|----------|--------|
| 36    | 25   | 25         | 30 (6)   | 99     |
| 37    | 25   | 50-55      | 12 (2)   | 100    |
| 38    | 25   | 60-65      | 14 (0.2) | 59     |
| 39    | 40   | 25         | 50 (10)  | 68     |
| 40    | 40   | 50-55      | 40 (9)   | 72     |
| 41    | 40   | 60-65      | 32 (1)   | 66     |

Haze (std. dev.)

The results in Table 6 show that haze may be reduced by about 20% (Example 41 v. Example 39) and up to as much as about 65% (Example 37 v. Example 36) by increasing the cure temperature. Decreasing diluent concentration from 40 to 25% decrease haze by between about 40 and 75%.

Examples 42-47

Lenses were made from the formulations shown in Table 8 using the procedure of Example 1, with a 30 minute cure time at 25°C and an intensity of about 2.5 mW/cm<sup>2</sup>. Percent haze was measured and is reported in Table

5 7.

10 A comparison of the results for formulations having the same amount of diluent and either TEGDMA or acPDMS (Examples 42 and 46 and Examples 43 and 47) shows that acPDMS is an effective crosslinker and provides lenses with properties which are comparable to those where TEGDMA is used as a crosslinker. Examples 44 and 45 contain both

15 crosslinkers. Haze for these Examples decreased substantially compared to the lenses made from either crosslinker alone. However, modulus and elongation were negatively impacted (likely because the amount of crosslinker was too great).

Examples 48-52

Reaction mixtures were made using the formulations shown in Table 8 with a mixture of 72.5% t-amyl alcohol and 27.5% PVP ( $M_w = 2500$ ) as the diluent. The reaction mixtures were placed into thermoplastic contact lens molds, and irradiated using Philips TL 20W/03T fluorescent bulbs at 45°C, 0.8 mW/cm<sup>2</sup> for about 32 minutes. The molds were opened and lenses were released into deionized water at 95°C over a period of 20 minutes. The lenses were then placed into borate buffered saline solution for 60 minutes and autoclaved at 122°C and 30 minutes. The properties of the resulting lenses are shown in Table 9.

Diluents (weight parts):

A = 72.5% t-amyl alcohol and 27.5 PVP ( $M_w = 2500$ )

B = t-amyl alcohol  
C = 15/38/38% TMP/2M2P/ PVP ( $M_w = 2500$ )  
D = 57/43 2M2P/TMP

5 NT – not tested

Thus, Examples 48, 51 show that formulations comprising both hydrophilic (EGDMA or TEGDMA) and hydrophobic crosslinkers (acPDMS) provide silicone hydrogel compositions which display an excellent balance of properties including good water content, moderate Dk, wettability, modulus and elongation.

#### Example 55

The lenses of Example 48 were clinically evaluated. The lenses were worn by 18 patients in a daily wear mode (nightly removal) for a period of one week. At one week the PLTF-NIBUT was 8.4 ( $\pm 2.9$ ) seconds compared to 7.0 ( $\pm 1.3$ ) seconds for ACUVUE® 2 lenses. The front surface discrete deposition was graded none to slight for 97% of the patients with the test lenses, compared with 89% in control lenses. The movement was acceptable for both test and control lenses.

#### Example 56

The lenses of Example 49 were clinically evaluated. The lenses were worn by 18 patients in a daily wear mode (nightly removal) for a period of one week. At one week the PLTF-NIBUT was 8.4 ( $\pm 2.9$ ) seconds compared to 7 ( $\pm 1.3$ ) seconds for ACUVUE® 2 lenses. The front surface discrete deposition was graded none to slight for 95% of the patients with the test lenses, compared with 89% in control lenses. The movement was acceptable for both test and control lenses.

#### Example 57

The lenses of Example 51 were clinically evaluated. The lenses were worn by 13 patients in a daily wear mode (nightly removal) for a period of one week. At one week the PLTF-NIBUT was 4.3 ( $\pm 1.9$ ) seconds compared to 9.6 ( $\pm 2.1$ ) seconds for ACUVUE® 2 lenses. The front surface discrete deposition was graded none to slight for 70% of the patients with the test lenses, compared with 92% in control lenses. The movement was acceptable for

both test and control lenses. Thus, there is some correlation between contact angle measurements (108° for Example 51 versus 52° for Example 48) and clinical wettability as measure by PLTF-NIBUT (4.3 seconds for Example 51 versus 8.4 seconds for Example 48).

5

#### Examples 58-68

Silicone hydrogel lenses were made using the components listed in Table 9 and the following procedure:

10       The components were mixed together in a jar to for a reaction mixture. The jar containing the reaction mixture was placed on a jar mill roller and rolled overnight.

15       The reaction mixture was placed in a vacuum desiccator and the oxygen removed by applying vacuum for 40 minutes. The desiccator was back filled with nitrogen. Contact lenses were formed by adding approximately 0.10 g of the degassed lens material to the concave front curve side of TOPAS® mold cavities in a glove box with nitrogen purge. The molds were closed with polypropylene convex base curve mold halves. Polymerization was carried out under a nitrogen purge and was photoinitiated with 5 mW cm<sup>2</sup> of visible light generated using 20W fluorescent lights with a TL-03 phosphor. After curing for 25 minutes at 45°C, the molds were opened. The concave front curve portion of the lens mold was placed into a sonication bath (Aquasonic model 75D) containing deionized water under the conditions (temperature and amount of Tween) shown in Table 10. The lens deblock time is shown in Table 10. The lenses were clear and of the proper shape to be contact lenses.

5 Example 69

The lenses of Example 59 which were deblocked in Example 66, were further hydrated in deionized water at 65°C for 20 minutes. The lenses were then transferred into borate buffered saline solution and allowed to equilibrate for at least about 24 hours. The lenses were clear and of the proper shape to be contact lenses. The lenses had a water content of 43%, a modulus of 87 psi, an elongation of 175%, and a Dk of 61 barriers. The lenses were found to have an advancing contact angle of 57 degrees. This indicates the lenses were substantially free of hydrophobic material.

15 Example 70

The concave front curve portion of the lens mold from Example 61 was placed into a sonication bath (Aquasonic model 75D) containing about 5% DOE-120 in deionized water at about 75°C. The lenses deblocked from the frame in 18 minutes.

20

Example 71 (use of an organic solvent)

The concave front curve portion of the lens mold from example 61 was placed into a sonication bath (Aquasonic 75D) containing about 10% of 2-propanol an organic solvent in deionized water at 75°C. The lenses deblocked form the frame in 15 minutes. When Tween was used as the additive (Example 68) the deblock time was 18 minutes. Thus, the present

25

example shows that organic solvents may also be used to deblock lenses comprising low molecular weight hydrophilic polymers.

EXAMPLE 72 (contains no low molecular weight PVP)

5           Silicone hydrogel lenses were made using the formulation and procedure of Example 58, but without any low molecular weight PVP. The following procedure was used to deblock the lenses.

          The concave front curve portion of the lens mold was placed into a sonication bath (Aquasonic model 75D) containing about 850ppm of Tween in  
10       deionized water at about 65°C. The lenses did not release from the mold. The deblock time for the formulation which contained low molecular weight hydrophilic polymer (Example 58 formulation) under similar deblock conditions (Example 62 - 850 ppm Tween and 75°C) was 10 minutes. Thus, the present  
15       Example shows that deblocking cannot be accomplished in water only, in this formulation without including low molecular weight hydrophilic polymer in the formulation.

Example 73

          The concave front curve portion of the lens mold from example 72 was  
20       placed into a sonication bath (Aquasonic 75D) containing about 10% of 2-propanol an organic solvent in deionized water at 75°C. The lenses deblocked from the frame in 20 to 25 minutes. Thus, lenses of the present invention which do not contain low molecular weight hydrophilic polymer may be deblocked using an aqueous solution comprising an organic solvent.

25

Examples 74-76

          Formulations were made according to Example 49, but with varying amounts of photoinitiator (0.23, 0.38 or 0.5 wt.%), curing at 45°C with Philips TL 20W/03T fluorescent bulbs (which closely match the spectral output of the  
30       visible light used to measure gel time) irradiating the molds at 2.0 mW/cm<sup>2</sup>. The advancing contact angles of the resulting lenses are shown in Table 11.

**Table 11**

| Ex. # | Wt% | Advancing DCA | Gel time (sec) |
|-------|-----|---------------|----------------|
|-------|-----|---------------|----------------|

|    |      |        |    |
|----|------|--------|----|
| 74 | 0.23 | 59 (4) | 65 |
| 75 | 0.38 | 62 (6) | 57 |
| 76 | 0.5  | 80 (7) | 51 |

Examples 77-79

Gel times were measured for the formulation of Example 1 at 45°C at  
 5 1.0, 2.5 and 5.0 mW/cm<sup>2</sup>. The results are shown in Table 12.

**Table 12**

| Ex. # | Intensity<br>(mW/cm <sup>2</sup> ) | gel time (sec) |
|-------|------------------------------------|----------------|
| 77    | 1                                  | 52             |
| 78    | 2.5                                | 38             |
| 79    | 5                                  | 34             |

10 The results of Examples 74 through 76 and 77 through 79 compared  
 with Examples 27-35, show that as gel times increase, wettability improves.  
 Thus, gel points can be used, in coordination with contact angle  
 measurements, to determine suitable cure conditions for a given polymer  
 formulation and photoinitiator system.

15

Example 80 (Macromer Preparation)

To a dry container, which was housed in a dry box under nitrogen at  
 ambient temperature was added 30.0 g (0.277 mol) of  
 20 bis(dimethylamino)methylsilane (a water scavenger), a solution of 13.75 ml of  
 a 1M solution of TBACB (386.0 g TBACB in 1000 ml dry THF), 61.39 g (0.578  
 mol) of p-xylene, 154.28 g (1.541 mol) methyl methacrylate (1.4 equivalents  
 relative to initiator), 1892.13 (9.352 mol) 2-(trimethylsiloxy)ethyl methacrylate  
 (8.5 equivalents relative to initiator) and 4399.78 g (61.01 mol) of THF. This  
 25 mixture was charged to a dry, three-necked, round-bottomed flask equipped  
 with a thermocouple and condenser, all connected to a nitrogen source.

The initial mixture was cooled to 15 °C while stirring and purging with  
 nitrogen. After the solution reached 15 °C, 191.75 g (1.100 mol) of 1-  
 trimethylsiloxy-1-methoxy-2-methylpropene (1 equivalent) was injected into  
 30 the reaction vessel. The reaction was allowed to exotherm to approximately  
 62 °C and then 30 ml of a 0.40 M solution of 154.4 g TBACB in 11 ml of dry

THF was metered in throughout the remainder of the reaction. After the temperature of reaction reached 30 °C and the metering began, a solution of 467.56 g (2.311 mol) 2-(trimethylsiloxy)ethyl methacrylate (2.1 equivalents relative to the initiator), 3636.6 g (3.463 mol) n-butyl

- 5 monomethacryloxypropyl-polydimethylsiloxane (3.2 equivalents relative to the initiator), 3673.84 g (8.689 mol) TRIS (7.9 equivalents relative to the initiator) and 20.0 g bis(dimethylamino)methylsilane was added.

- This mixture was allowed to exotherm to approximately 38-42 °C and then allowed to cool to 30 °C. At that time, a solution of 10.0 g (0.076 mol) 10 bis(dimethylamino)methylsilane, 154.26 g (1.541 mol) methyl methacrylate (1.4 equivalents relative to the initiator) and 1892.13 g (9.352 mol) 2-trimethylsiloxy)ethyl methacrylate (8.5 equivalents relative to the initiator) was added and the mixture again allowed to exotherm to approximately 40 °C. The reaction temperature dropped to approximately 30 °C and 2 gallons of 15 THF were added to decrease the viscosity. A solution of 439.69 g water, 740.6 g methanol and 8.8 g (0.068 mol) dichloroacetic acid was added and the mixture refluxed for 4.5 hours to remove the trimethylsiloxy protecting groups on the HEMA. Volatiles were then removed and toluene added to aid in removal of the water until a vapor temperature of 110 °C was reached.

- 20 The reaction flask was maintained at approximately 110 °C and a solution of 443 g (2.201 mol) TMI and 5.7 g (0.010 mol) dibutyltin dilaurate were added. The mixture was reacted until the isocyanate peak was gone by IR. The toluene was evaporated under reduced pressure to yield an off-white, anhydrous, waxy reactive macromer. The macromer was placed into acetone 25 at a weight basis of approximately 2:1 acetone to macromer. After 24 hrs, water was added to precipitate out the macromer and the macromer was filtered and dried using a vacuum oven between 45 and 60 °C for 20-30 hrs.

#### Examples 81- 88]

- 30 Reaction mixtures were made in a nitrogen-filled glove box using the formulations shown in Table 12 with a D3O and/or IPL as the diluent. The reaction mixtures were placed into thermoplastic contact lens molds, and irradiated using Philips TL 20W/03T fluorescent bulbs at 50°C, for about 60 minutes. The molds were opened and lenses were released IPA, leached

and transferred into borate buffered saline. The properties of the resulting lenses are shown in Table 13.

Table 13

5

Example 89

The lenses of Example 83 were clinically evaluated. The lenses were worn by 10 patients in a daily wear mode (nightly removal) for a period of 30 minutes. For each patient, the test lens was worn in one eye and an Bauch & Lomb Purevision lens was worn in the contralateral eye. At thirty minutes the PLTF-NIBUT was 7.5 ( $\pm 1.6$ ) seconds compared to 8.6 ( $\pm 1.6$ ) seconds for the Bausch & Lomb Purevision lens. . The front surface discrete deposition was graded none to slight for 100% of the patients with the test lenses, compared with 100% in control lenses. The movement was acceptable for both test and control lenses. The lenses of the present invention are comparable in performance to the B&L lens, which has a plasma coating. Thus, the present

Example shows that lenses formed from a polymer network comprising a siloxane containing macromer, high molecular weight hydrophilic polymer and a compatibilizing component display good wettability and deposition resistance without a coating.

5

#### Example 90

Trifluoromethane sulfonic acid (2.3 ml) was added to 27.8 g 1,3-bis(hydroxybutyl)tetramethyldisiloxane and 204.4 g octamethylcyclotetrasiloxane. The resulting solution was stirred overnight. 17.0 g Na<sub>2</sub>CO<sub>3</sub> were added and the mixture was stirred for one hour. About 50 ml hexane was added and the mixture was stirred for about one hour, then filtered. The hexane was evaporated under reduced pressure and cyclics were removed by heating to 110°C at < 1 mBar for about one hour to produce hydroxybutyl terminated polydimethylsiloxane.

In a separate flask 12.2 g CH<sub>2</sub>OH terminated Fluorolink® Polymer Modifier D10 with an average equivalent weight of 500 (Ausimont USA, equivalent to Fomblin® ZDOL) was combined with 11.8 mg dibutyltin dilaurate. The resulting solution was evacuated to about 20 mBar twice, each time refilling with dry N<sub>2</sub>. 5.0 ml isophorone diisocyanate was added and the mixture was stirred overnight under N<sub>2</sub> to produce a clear viscous product.

47.7 g of the hydroxybutyl terminated polydimethylsiloxane from above was combined with 41.3 grams anhydrous toluene. This solution was combined with the Fluorolink®-Isophorone diisocyanate product and the resulting mixture was stirred under nitrogen overnight. The toluene was evaporated from the product over about 5 hours at < 1 mBar. 3.6 g 2-isocyanatoethyl methacrylate was added and the resulting mixture was stirred under N<sub>2</sub> for four days to produce a slightly opaque viscous liquid fluorosilicone macromer.

#### Example 91

2.60 g of the fluorosilicone macromer made in Example 90 was combined with 1.12 g ethanol, 1.04 g TRIS, 1.56 g DMA, 32 mg Darocur 1173 to produce a slightly hazy blend containing 18% diluent (ethanol). Contact lenses were made from this blend in plastic molds (Topas) curing 30 minutes under fluorescent UV lamps at room temperature in a N<sub>2</sub> atmosphere. The

molds were opened, and the lenses released (deblocked) into ethanol. The lenses were leached with CH<sub>2</sub>Cl<sub>2</sub> and then IPA for about 30 minutes each at room temperature, then placed into borate buffered saline for about 2 hours and then autoclave at 121°C for 30 minutes. The resulting lenses were tacky to the touch and had a tendency to stick to each other. The advancing DCA of these lenses was measured and is shown in Table 14.

#### Example 92-88

Reaction mixtures were made using the reactive components (amounts based upon reactive components) shown in Table 14 and D3O as a diluent. The amount of D3O is based upon the total amount of reactive components and diluent. The reaction mixture and lenses were made using procedure of Example 91. The resulting lenses were slippery to the touch and did not stick to each other.

The advancing DCA of these lenses was measured and is shown in Table 14, below.

**Table 14**

| Example                  | 92      | 93    | 94     |
|--------------------------|---------|-------|--------|
| Component (wt %)         |         |       |        |
| Fluorosilicone macromer  | 49.7    | 28.5  | 19     |
| TRIS                     | 19.9    | 0     | 0      |
| DMA                      | 29.8    | 24.8  | 24.7   |
| PVP (K90)                | 0       | 5     | 4.9    |
| SiGMA                    | 0       | 40.7  | 50.1   |
| EGDMA                    | 0       | 0.4   | 0.6    |
| Darocur 1173             | 0.6     | 0.6   | 0.6    |
| Diluent                  | Ethanol | D3O   | D3O    |
| % Diluent in final blend | 18      | 18    | 18     |
| Advancing DCA            | 132 (8) | 69(7) | 59 (9) |

Examples 92 through 94 clearly show that hydrophilic polymer may be used to improve wettability. In these Examples contact angles are reduced by up to about 50% (Example 93) and up to about 60% (Example 94). Compositons comprising higher amounts of fluorosilicone macromer and hydrophilic polymer can also be made by functionalizing the fluorosilicone macromer to include active hydrogens.

Examples 95-99

Reaction mixtures were made using reactive components shown in Table 15 and 29% (based upon all reactive components and diluent) t-amyl alcohol as a diluent and 11% PVP 2,500 (based upon reactive components).

- 5 Amounts indicated are based upon 100% reactive components. The reaction mixtures were placed into thermoplastic contact lens molds, and irradiated using Philips TL 20W/03T fluorescent bulb at 60°C, 0.8 mW/cm<sup>2</sup> for about 30 minutes under nitrogen. The molds were opened and lenses were released into deionized water at 95°C over a period of 15 minutes. The lenses were
- 10 then placed into borate buffered saline solution for 60 minutes and autoclaved at 122° C for 30 min. The properties of the resulting lenses are shown in Table 15.

**Table 15**

| Ex. #             | 95     | 96     | 97     | 98    | 99    |
|-------------------|--------|--------|--------|-------|-------|
| Components        |        |        |        |       |       |
| SiGMA             | 30     | 30     | 30     | 30    | 30    |

| HEMA              | 8.5    | 8.5    | 8.5    | 8.5   | 8.5   |
| Norbloc           | 1.5    | 1.5    | 1.5    | 1.5   | 1.5   |
| CGI 819           | 0.25   | 0.25   | 0.25   | 0.25  | 0.25  |
| EGDMA             | 0.75   | 0.75   | 0.75   | 0.75  | 0.75  |
| <u>Properties</u> |        |        |        |       |       |
| DCA (advancing)   | 122(8) | 112(6) | 66(13) | 58(8) | 54(3) |
| Haze              | 18(4)  | 11(1)  | 13(1)  | 14(2) | 12(1) |

15

- Table 15 shows that the addition of PVP dramatically decreases contact angle. As little as 1% decreases the dynamic contact angle by about 10% and as little as 3% decreases dynamic contact angle by about 50%. These improvements are consistent with those observed for macromer based
- 20 polymers, such as those in Examples 92-94.

Example 100

Preparation of mPDMS-OH (used in Examples 3)

96 g of Gelest MCR-E11 (mono-(2,3-epoxypropyl)-propyl ether terminated polydimethylsiloxane(1000 MW)), 11.6 g methacrylic acid, 0.10 g triethylamine and 0.02 g hydroquinone monomethylether were combined and heated to 140°C with an air bubbler and with stirring for 2.5 hours. The product was extracted with saturated aqueous  $\text{NaHCO}_3$  and  $\text{CH}_2\text{Cl}_2$ . The  $\text{CH}_2\text{Cl}_2$  layer was dried over  $\text{Na}_2\text{SO}_4$  and evaporated to give 94 g of product. HPLC/MS was consistent with desired structure:

5

10

What is claimed is

1. A wettable silicone hydrogel comprising the reaction product of  
at least one siloxane containing macromer ;  
at least one high molecular weight hydrophilic polymer; and  
5 at least one compatibilizing component.
2. The hydrogel of claim 1 wherein said siloxane containing macromer is  
present in an amount between about 5% to about 50%.
3. The hydrogel of claim 1 wherein the siloxane containing macromer or  
prepolymer is present in an amount between about 10% to about 50%.
- 10 4. The hydrogel of claim 1 wherein the siloxane containing macromer or  
prepolymer is present in an amount between about 15% to about 45%.
5. The hydrogel of claim 1 wherein said at least one siloxane containing  
macromer comprises at least one siloxane group, and at least one  
second group selected from the group consisting of urethane groups,  
15 alkylene groups, alkylene oxide groups, polyoxyalkylene groups,  
arylene groups, alkyl esters, amide groups, carbamate groups,  
perfluoroalkoxy groups, isocyanate groups, combinations thereof.
6. The hydrogel of claim 5 wherein said at least one siloxane containing  
macromers is formed via polymerizing said siloxane group with at least  
20 one acrylic or methacrylic compound.
7. The hydrogel of claim 5 wherein said at least one siloxane containing  
macromer is selected from the group consisting of methacrylate  
functionalized, silicone-fluoroether urethane macromers, methacrylate  
functionalized, silicone urethane macromers, styrene functionalized  
25 prepolymers of hydroxyl functional methacrylates and silicone  
methacrylates and vinyl carbamate functionalized polydimethylsiloxane
8. The hydrogel of claim 1 comprising about 1% to about 15% high  
molecular weight hydrophilic polymer.
9. The hydrogel of claim 1 comprising about 3% to about 15% high  
30 molecular weight hydrophilic polymer.
10. The hydrogel of claim 1 comprising about 5% to about 12% high  
molecular weight hydrophilic polymer.
11. The silicone hydrogel of claim 14 wherein said hydrophilic polymer is  
selected from the group consisting of polyamides, polylactones,

polyimides, polylactams, functionalized polyamides, functionalized polylactones, functionalized polyimides, functionalized polylactams, and mixtures thereof.

12. The silicone hydrogel of claim 14 wherein said hydrophilic polymer is selected from the group consisting of poly-N-vinyl pyrrolidone, poly-N-vinyl-2- piperidone, poly-N-vinyl-2-caprolactam, poly-N-vinyl-3-methyl-2- caprolactam, poly-N-vinyl-3-methyl-2-piperidone, poly-N-vinyl-4-methyl-2- piperidone, poly-N-vinyl-4-methyl-2-caprolactam, poly-N-vinyl-3-ethyl-2- pyrrolidone, and poly-N-vinyl-4,5-dimethyl-2-pyrrolidone, polyvinylimidazole, poly-N-N-dimethylacrylamide, polyvinyl alcohol, polyacrylic acid, polyethylene oxide, poly 2 ethyl oxazoline, heparin polysaccharides, polysaccharides, mixtures and copolymers thereof
13. The hydrogel of claim 1, wherein the high molecular weight hydrophilic polymer is poly-N-vinylpyrrolidone.
14. The silicone hydrogel of claim 1 wherein said compatibilizing component is a compound of Formula I or II

wherein:

- 25 n is an integer between 3 and 35

R<sup>1</sup> is hydrogen, C<sub>1-6</sub>alkyl,

R<sup>2</sup>, R<sup>3</sup>, and R<sup>4</sup>, are independently, C<sub>1-6</sub>alkyl, triC<sub>1-6</sub>alkylsiloxy, phenyl, naphthyl, substituted C<sub>1-6</sub>alkyl, substituted phenyl, or substituted naphthyl

where the alkyl substituents are selected from one or more members of the group consisting of C<sub>1-6</sub>alkoxycarbonyl, C<sub>1-6</sub>alkyl, C<sub>1-6</sub>alkoxy, amide, halogen, hydroxyl, carboxyl, C<sub>1-6</sub>alkylcarbonyl and formyl, and where the aromatic substituents are selected from one or more members of the group consisting of C<sub>1-6</sub>alkoxycarbonyl, C<sub>1-6</sub>alkyl, C<sub>1-6</sub>alkoxy, amide, halogen, hydroxyl, carboxyl, C<sub>1-6</sub>alkylcarbonyl and formyl;

R<sup>5</sup> is a hydroxyl, an alkyl group containing one or more hydroxyl groups, or (CH<sub>2</sub>(CR<sup>9</sup>R<sup>10</sup>)<sub>y</sub>O)<sub>x</sub>-R<sup>11</sup> wherein y is 1 to 5, preferably 1 to 3, x is an integer of 1 to 100, preferably 2 to 90 and more preferably 10 to 25; R<sup>9</sup> - R<sup>11</sup> are independently selected from H, alkyl having up to 10 carbon atoms and alkyls having up to 10 carbon atoms substituted with at least one polar functional group;

R<sup>6</sup> is a divalent group comprising up to 20 carbon atoms;

R<sup>7</sup> is a monovalent group that can undergo free radicals or cationic polymerization, comprising up to 20 carbon atoms, and

R<sup>8</sup> is a divalent or trivalent group comprising up to 20 carbon atoms.

15. The silicone hydrogel of claim 1 wherein said hydroxyl-functionalized silicone-containing monomer is selected from the group consisting of 2-propenoic acid, 2-methyl-2-hydroxy-3-[3-[1,3,3,3-tetramethyl-1-[trimethylsilyl]oxy]disiloxanyl]propoxy]propyl ester, (3-methacryloxy-2-hydroxypropyloxy)propyltris(trimethylsiloxy)silane, (2-methacryloxy-3-hydroxypropyloxy)propylbis(trimethylsiloxy)methylsilane and mixtures thereof.

16. The hydrogel of claim 1 wherein said compatibilizing component comprises at least one compound of Formula III:

Wherein x is 1 to 10;

IWA is a difunctional hydrophilic polymer having a number average molecular weight of between about 1000 and about 50,000 Daltons; and

HB is a difunctional moiety comprising at least one N which is capable of hydrogen bonding.

17. The hydrogel of claim 16 wherein said IWA is derived from  $\alpha,\omega$ -hydroxyl terminated PVP and  $\alpha,\omega$ -hydroxyl terminated polyoxyalkylene glycols.
18. The hydrogel of claim 16 wherein HB is a difunctional group selected from the group consisting of amides, imides, carbamates ureas, and combinations thereof.
19. The hydrogel of claim 1 wherein said compatibilizing component is present in an amount between about 5 and about 90 weight%.
20. The hydrogel of claim 1 further comprising at least one oxygen permeable component in addition to said siloxane containing macromer or prepolymer.
21. The hydrogel of claim 20 wherein said oxygen permeable component is selected from the group consisting of amide analogs of 3-methacryloxypropyltris(trimethylsiloxy)silane; siloxane vinyl carbamate analogs, siloxane vinyl carbonate analogs, and siloxane containing monomers, combinations and oligomers thereof.
22. The hydrogel claim 20 wherein said oxygen permeable component is selected from the group consisting of 3-methacryloxypropyltris(trimethylsiloxy)silane, monomethacryloxypropyl terminated polydimethylsiloxanes, polydimethylsiloxanes, 3-methacryloxypropylbis(trimethylsiloxy)methylsilane, methacryloxypropylpentamethyl disiloxane and combinations thereof.
23. The hydrogel of claim.20 wherein said oxygen permeable component is present in an amount of 0 to about 80 weight %.
24. The hydrogel of 20 wherein said oxygen permeable component is present in an amount of about 5 to about 60%.
25. The hydrogel of claim.20 wherein said oxygen permeable component is present in an amount of about 10 to about 40%.
26. The hydrogel of claim 1 further comprising at least one hydrophilic monomer.
27. The hydrogel claim 26 wherein said at least one hydrophilic monomer comprises at least one acrylic group, vinyl group or a combination thereof.

28. . The hydrogel of claim 27 wherein said acrylic group has the formula  $\text{CH}_2=\text{CRCOX}$ , where R is hydrogen or  $\text{C}_{1-6}$ alkyl and X is O or N.
29. .The hydrogel of claim 26 wherein said at least one hydrophilic monomer is selected from the group consisting of
- 5 N,N-dimethylacrylamide, 2-hydroxyethyl methacrylate, glycerol methacrylate, 2-hydroxyethyl methacrylamide, polyethyleneglycol monomethacrylate, methacrylic acid, acrylic acid, N-vinyl pyrrolidone, N-vinyl-N-methyl acetamide, N-vinyl-N-ethyl acetamide, N-vinyl-N-ethyl formamide, N-vinyl formamide, hydrophilic vinyl carbonate monomers,
- 10 vinyl carbamate monomers, hydrophilic oxazolone monomers, polydextran and copolymers and combinations thereof.
30. The hydrogel of claim 26 wherein said at least one hydrophilic monomer comprises at least one polyoxyethylene polyols having one or more of the terminal hydroxyl groups replaced with a functional
- 15 group containing a polymerizable double bond.
31. The hydrogel of claim 26 wherein said at least one hydrophilic monomer is selected from the group consisting of polyethylene glycol, ethoxylated alkyl glucoside, and polyethylene polyols having one or more terminal polymerizable olefinic groups bonded to the polyethylene
- 20 polyol.
32. The hydrogel of claim 26 wherein said at least one hydrophilic monomer is selected from the group consisting of N,N-dimethylacrylamide, 2-hydroxyethyl methacrylate, glycerol methacrylate, 2-hydroxyethyl methacrylamide, N-vinylpyrrolidone,
- 25 polyethyleneglycol monomethacrylate, methacrylic acid, acrylic acid and combinations thereof.
33. The hydrogel of claim 26 wherein said at least one hydrophilic monomer comprises N,N-dimethylacrylamide.
34. The hydrogel of claim 26 wherein said at least one hydrophilic
- 30 monomer is present in amounts of about 0 to about 70 weight%.
35. The hydrogel of claim 26 wherein said at least one hydrophilic monomer is present in amounts of about 5 to about 60 weight%.
36. The hydrogel of claim 26 wherein said at least one hydrophilic monomer is present in amounts of about 10 to 50 weight%.

37. The hydrogel of claim 1 comprising about 1 to about 15 weight% high molecular weight hydrophilic polymer and about 5 to about 90 weight % hydroxyl-functionalized silicone-containing monomer.
- 5 38. The hydrogel of claims 1 comprising about 1% to about 15% high molecular weight hydrophilic polymer; about 5 to about 90 weight% compatibilizing component; about 5 to about 50 weight% said siloxane containing macromer, 0 to about 80 weight% siloxane containing monomer and 0 to about 70 weight % hydrophilic monomer.
- 10 39. The hydrogel of claim 1 comprising about 3% to about 15% high molecular weight hydrophilic polymer; about 10 to about 80 weight% compatibilizing component; about 10 to about 50 weight% said siloxane containing macromer or prepolymer, 5 to about 60 weight% siloxane containing monomer and 5 to about 60 weight % hydrophilic monomer.
- 15 40. The hydrogel of claim 1 comprising about 5% to about 12% high molecular weight hydrophilic polymer; about 15 to about 55 weight% compatibilizing component; about 15 to about 45 weight% said siloxane containing macromer, 10 to about 40 weight% oxygen permeable component and 10 to about 50 weight % hydrophilic monomer.
- 20 41. A silicone hydrogel contact lens comprising the hydrogel of claim 1 and wherein said contact lens is not surface modified.
42. The lens of of claim 41, wherein the contact lens is a soft contact lens.
43. The lens of claim 41 wherein said lens has an advancing dynamic
- 25 contact angle of less than about 70°.
- 44.4 The lens of claim 41 wherein said lens has an advancing dynamic contact angle of less than about 60°.
45. The lens of claim 41 wherein said lens, after about one day of wear, has a tear film break up time of at least about 7 seconds.
- 30 46.4 The lens of claim 41 wherein said lens further comprises a modulus of less than about 90 psi.
- 47.4The lens of claims 41 wherein said lens further comprises a water content between about 10 and about 60%.

48. The hydrogel of claim 1 wherein said high molecular weight hydrophilic polymer is present in an amount sufficient to provide an article formed from said hydrogel with an advancing dynamic contact angle which is at least about 10% lower than a hydrogel without said hydrophilic polymer.
49. The hydrogel of claim 1 wherein said hydrogel is an interpenetrating network or a semi-interpenetrating network.
50. A method comprising the steps of (a) mixing reactive components comprising at least one high molecular weight hydrophilic polymer, at least one siloxane containing macromer and an effective amount of at least one compatibilizing component and (b) curing the product of step (a) to form a biomedical device.
51. The method of claim 50 wherein said biomedical device comprises an ophthalmic device.
52. The method of claim 50 wherein said ophthalmic device is a silicone hydrogel contact lens.
53. The method of claim 50 wherein said reactive components are mixed in the presence of a diluent to form a reaction mixture.
54. The method of claim 53 wherein said diluent is selected from the group consisting of ethers, esters, alkanes, alkyl halides, silanes, amides, alcohols and mixtures thereof.
55. The method of claim 53 wherein said diluent selected from the group consisting amides, alcohols and mixtures thereof.
56. The method of claim 53 wherein said diluent selecting the group consisting of tetrahydrofuran, ethyl acetate, methyl lactate, i-propyl lactate, ethylene chloride, octamethylcyclotetrasiloxane, dimethyl formamide, dimethyl acetamide, dimethyl propionamide, N methyl pyrrolidinone mixtures thereof and mixtures of any of the foregoing with at least one alcohol.
57. The method of claim 53 wherein said diluent comprises at least one alcohol having at least 4 carbon atoms.
58. The method of claim 53 wherein said diluent comprises at least one alcohol having at least 5 carbons atoms.

59. The method of claim 53 wherein said diluents are inert and easily displaceable with water.
60. The method of claim 53 wherein said diluent comprises at least one alcohol selected from the group consisting of tert-butanol, tert-amyl alcohol, 2-butanol, 2-methyl-2-pentanol, 2,3-dimethyl-2-butanol, 3-methyl-3-pentanol, 3-ethyl-3-pentanol, 3,7-dimethyl-3-octanol and mixtures thereof.
61. The method of claim 53 wherein said diluent is selected from the group consisting of hexanol, heptanol, octanol, nonanol, decanol, tert-butyl alcohol, 3-methyl-3-pentanol, isopropanol, t amyl alcohol, ethyl lactate, methyl lactate, i-propyl lactate, 3,7-dimethyl-3-octanol, dimethyl formamide, dimethyl acetamide, dimethyl propionamide, N methyl pyrrolidinone and mixtures thereof.
62. The method of claim 53 wherein said diluent is selected from the group consisting of 1-ethoxy-2-propanol, 1-methyl-2-propanol, t-amyl alcohol, tripropylene glycol methyl ether, isopropanol, 1-methyl-2-pyrrolidone, N,N-dimethylpropionamide, ethyl lactate, dipropylene glycol methyl ether and mixtures thereof.
63. The method of claim 53 wherein said diluent is present in an amount less than about 40 weight% based upon the reaction mixture.
64. The method of claim 53 wherein said diluent is present in an amount between about 10 and about 30 weight% based upon the reaction mixture.
65. The method of claim 53 wherein said diluent is water soluble at processing conditions and said process further comprises (c) removing said lens from a mold in which said lens was cured and (d) hydrating said lens, wherein both steps (c) and (d) are performed in aqueous solutions which comprise water as a substantial component.
66. The method of claim 53 wherein said curing is conducted via heat, exposure to radiation or a combination thereof and said reaction mixture further comprises at least one initiator.
67. The method of claim 66 wherein said curing is conducted via irradiation comprises ionizing and/or actinic radiation and said initiator comprises at least one photoinitiator.

68. The method of claim 67 wherein said radiation comprises light having a wavelength of about 150 to about 800nm and said initiator is selected from the group consisting of aromatic alpha-hydroxy ketones, alkoxydoxybenzoin, acetophenones, acyl phosphine oxides, mixtures of tertiary amines and diketones, and mixtures thereof.
69. The method of claim 67 wherein said initiator is selected from the group consisting of 1-hydroxycyclohexyl phenyl ketone, 2-hydroxy-2-methyl-1-phenyl-propan-1-one, bis(2,6-dimethoxybenzoyl)-2,4,4-trimethylpentyl phosphine oxide, bis(2,4,6-trimethylbenzoyl)-phenylphosphineoxide, 2,4,6-trimethylbenzoyldiphenyl phosphine oxide and 2,4,6-trimethylbenzoyl diphenylphosphine oxide, benzoin methyl ester, combinations of camphorquinone and ethyl 4-(N,N-dimethylamino)benzoate and mixtures thereof.
70. The method of claim 67 wherein said initiator is present in the reaction mixture in amounts from about 0.1 to about 2 weight percent based upon said reactive components.
71. The method of claim 67 wherein said curing is conducted via visible light irradiation.
72. The method of claim 71 wherein said initiator comprises 1-hydroxycyclohexyl phenyl ketone, bis(2,6-dimethoxybenzoyl)-2,4,4-trimethylpentyl phosphine oxide and mixtures thereof.
73. The method of claim 71 wherein said initiator comprises bis(2,4,6-trimethylbenzoyl)-phenylphosphineoxide.
74. The method of claims 67 wherein said reactive components further comprises at least one UV absorbing compound.
75. The method of claim 71 wherein said curing step is conducted at a cure intensity between about 0.1 and about 6 mW/cm<sup>2</sup>.
76. The method of claim 71 wherein said curing step is conducted at a cure intensity of between about 0.2 mW/cm<sup>2</sup> to about 3 mW/cm<sup>2</sup>.
77. The method of claims 75 wherein said curing step further comprises a cure time of at least about 1 minute.
78. The method of claims 75 wherein said curing step further comprises a cure time of between about 1 and about 60 minutes.

79. The method of claim 75 wherein said curing step further comprises a cure time of between about 1 and about 30 minutes.
80. The method of claim 75 wherein said curing step is conducted at a temperature greater than about 25°C.
- 5 81. The method of claim 75 wherein said curing step is conducted at a temperature between about 25°C and 70°C.
82. The method of claim 75 wherein said curing step is conduct at a temperature between about 40°C and 70°C.
- 10 83. The method of claim 53 wherein said reaction mixture is cured in a mold and said method further comprises the step deblocking said ophthalmic device from said mold.
84. The method of claim 83 wherein said reaction mixture further comprises at least one low molecular weight hydrophilic polymer.
- 15 85. The method of claim 84 wherein said low molecular weight hydrophilic polymer has a number average molecular weight of less than about 40,000 Daltons.
86. The method of claim 84 wherein said low molecular weight hydrophilic polymer has a number average molecular weight of less than about 20,000 Daltons.
- 20 87. The method of claim 84 wherein the low molecular weight polymer is selected from the group consisting of water soluble polyamides, lactams and polyethylene glycols, and mixtures thereof.
88. The method of claim 84 wherein the low molecular weight polymer is selected from the group consisting poly-vinylpyrrolidone, polyethylene glycols, poly 2 ethyl-2-oxazoline and mixtures thereof.
- 25 89. The method of claim 84 wherein the low molecular weight hydrophilic polymer is present in amounts up to about 20 weight% based upon the reaction mixture.
90. The method of claim 84 wherein the low molecular weight hydrophilic polymer is present in amounts between about 5 and about 20 weight% based upon the reaction mixture.
- 30 91. The method of claim 84 wherein said deblocking is conducted using an aqueous solution.

92. The method of claim 84 wherein said aqueous solution further comprises at least one surfactant.
93. The method of claim 92 wherein said surfactant comprises at least one non-ionic surfactant.
- 5 94. The method of claim 92 wherein said surfactant comprises TWEEN®, or DOE120.
95. The method of claim 92 wherein said surfactant is present in amounts up to about 10,000 ppm.
- 10 96. The method of claim 92 wherein said surfactant is present in amounts between about 100 and about 1200 ppm.
97. The method of claim 83 wherein said aqueous solution comprises at least one organic solvent.
98. The method of claim 83 wherein said deblocking is conducted at a temperature between about ambient and about 100°C.
- 15 99. The method of claim 83 wherein said deblocking is conducted at a temperature between about 70°C and about 95°C.
100. The method of claim 83 wherein said deblocking is conducted using agitation.
- 20 101. The method of claim 83 wherein said agitation comprises sonication.
102. A method comprising the steps of (a) mixing reactive components comprising a high molecular weight hydrophilic polymer and an effective amount of a compatibilizing component and (b) curing the product of step (a) at or above a minimum gel time, to form a wettable biomedical device.
- 25 103. The method of claim 102 wherein said device is a ophthalmic lens.
104. The method of claim 103 wherein said device is a contact lens.
105. The method of claim 103 wherein said lens comprises an advancing dynamic contact angle of about 80° or less.
- 30 106. The method of claim 103 wherein said lens comprises an advancing dynamic contact angle of about 70° or less.

107. The method of claim 103 wherein said lens comprises a tear film break up time of at least about 7 seconds.
108. The method of claim 103 wherein said reactive components further comprises at least one initiator
- 5 109. The method of claim 108 wherein said cure is conducted via irradiation and said conditions comprise an initiator concentration and cure intensity effective to provide said minimum gel time.
110. The method of claim 109 wherein said initiator is present in an amount up to about 1% based upon all reactive components.
- 10 111. The method of claim 109 wherein said initiator is present in an amount less than about 0.5% based upon all reactive components.
112. The method of claim 109 wherein said cure is conducted via irradiation at an intensity of less than about 5 mW/cm<sup>2</sup>.
113. The method of claim 109 wherein said gel time is at least about  
15 30 seconds.
114. The method of claim 109 wherein said gel time is at least about 35 seconds.
115. The method of claim 102 wherein said compatibilizing component is not a hydroxyl functionalized macromer made by group  
20 transfer polymerization.
116. The method of claim 102 wherein said reactive components further comprise at least one macromer.
117. The method of claim 50 wherein said compatibilizing component is not a hydroxyl functionalized macromer made by group transfer  
25 polymerization.
118. A method for improving the wettability of an ophthalmic device formed from a reaction mixture comprising adding at least one high molecular hydrophilic weight polymer and a compatibilizing effective amount of at least one compatibilizing component to said reaction  
30 mixture, wherein said compatibilizing component is not a styrene functionalized prepolymer made from hydroxyl functional methacrylates.
119. The method of claim 118 wherein said compatibilizing component has a compatibility index of greater than about 0.5.

120. The method of claim 118 wherein said compatibilizing component has a compatibility index of greater than about 1.
121. The method of claim 118 wherein said compatibilizing component comprises at least one siloxane group.
- 5 122. The method of claim 121 wherein said compatibilizing component further comprises hydroxyl functionality and has a Si to OH ratio of less than about 15:1.
123. The method of claim 121 wherein said compatibilizing component has a Si to OH ratio of between about 1:1 to about 10:1.
- 10 124. An ophthalmic lens comprising a silicone hydrogel which has, without surface treatment, a tear film break up time of at least about 7 seconds
125. A silicone hydrogel contact lens comprising at least one oxygen permeable component, at least one compatibilizing component and an amount of high molecular weight hydrophilic polymer sufficient to provide said device, without a surface treatment, with tear film break up time after about one day of wear of at least about 7 seconds.
- 15 126. A device comprising a silicone hydrogel contact lens which is substantially free from surface deposition without surface modification.
