

Description

Technical Field

This invention relates generally to reference circuits and, more particularly, to a circuit which provides reference voltages for bias current generators and the like.

Background Art

In general, bias reference circuits can be classified by the source of the voltage standard by which the bias currents are established. As noted in *Analysis and Design of Analog Integrated Circuits* by Paul R. Grey and Robert G. Meyer (John Wiley & Sons, 1977, pages 239—261), the most convenient standards are the V_{BE} of a transistor, the thermal voltage, V_T , and the breakdown voltage of a reverse-biased emitter-base junction of a transistor. While each of these voltage reference elements may be readily fabricated using conventional bipolar integrated circuit fabrication processes, it is significantly more difficult to fabricate the open-collector bipolar devices utilized in common V_{BE} reference circuits using conventional MOS integrated circuit fabrication processes. On the other hand, the reverse-biased emitter-base junction or Zener diode reference circuit, although manufacturable in most MOS fabrication processes, generally requires supply voltages exceeding 7 to 8 volts, and tends to introduce significant amounts of noise under reverse-breakdown conditions.

A circuit in accordance with the precharacterising portion of claim 1 has been disclosed in EP0052553, state of the art by virtue of Article 54(3) EPC. This patent utilises a diode connected MOS transistor as a reference voltage generator.

Brief Summary of Invention

It is an object of the present invention to provide an MOS bias current reference circuit which generates a bias voltage which is substantially supply voltage independent, using the V_{BE} of a bipolar transistor.

An object of an embodiment of the present invention is to provide a self-biasing MOS bias current reference circuit capable of generating complementary bias voltages even when used with relatively low supply voltages.

In accordance with the present invention there is provided; a bias current reference circuit comprising:

reference voltage means for providing a reference voltage proportional to a bias current;

reference current means coupled to reference voltage means, for providing a reference current proportional to the reference voltage;

bias voltage means coupled to the reference current means, for providing a bias voltage proportional to the reference current; and

bias current means coupled to the bias voltage means and to the reference voltage means, for providing the bias current proportional to the bias voltage for said reference voltage means characterised in that the reference voltage means

comprises a bipolar transistor having a base and collector thereof coupled together to a power supply voltage and an MOS transistor having the source thereof coupled to the emitter of the bipolar transistor.

Brief Description of the Drawing

The Figure illustrates in schematic form a bias current reference circuit constructed in accordance with the preferred embodiment of the present invention.

Description of the Preferred Embodiment

Shown in the drawing is a bias current reference circuit 10 construed in accordance with the preferred embodiment of the present invention. The reference circuit 10 is comprised generally of a reference voltage portion 12, a reference current portion 14, a bias voltage portion 16 and a bias current portion 18. In the reference voltage portion 12, an NPN bipolar transistor 20 has the base and collector thereof connected to a positive supply V_{DD} , and the emitter thereof connected to the source of a P-channel MOS transistor 22 which has the gate and drain thereof connected to the reference current portion 14 and to the bias current portion 18. In this configuration, a reference voltage with respect to the positive supply V_{DD} will be developed on the gate of the transistor 22 which is the sum of the V_{BE} of the diode-connected transistor 20 and the V_{GS} of the diode-connected transistor 22, the latter being proportional to a bias current directed therethrough by the bias current portion 18.

In the reference current portion 14, a P-channel MOS transistor 24 has the source thereof connected to the positive supply V_{DD} via a resistor 26, the gate thereof connected to the gate and drain of the transistor 22, and the drain thereof connected to the bias voltage portion 16. By constructing the transistor 24 to have the same ratio of channel width to channel length as the transistor 22 and thus the same current density, the gate to source voltage V_{GS} of the transistor 24 will be substantially the same as that of the transistor 22. Thus, the base-emitter voltage V_{BE} of the transistor 20 will be reflected across the resistor 26. The reference current portion 14 will therefore provide a reference current which is proportional to the reference voltage provided by the reference voltage portion 12.

In the bias voltage portion 16, an N-channel MOS transistor 28 has the source thereof connected to a negative supply V_{SS} , and the gate and drain thereof connected to the drain of the transistor 24 of the reference current portion 14. In this configuration, the diode-connected transistor 28 will develop a gate to source voltage V_{GS} which is proportional to the reference current. This voltage, indicated as V_{NB} , is suitable for biasing other N-channel MOS transistors used as constant bias current sinks.

In the bias current portion 18, an N-channel MOS transistor 30 as the source thereof connected to the negative supply V_{SS} , the gate there-

of connected to the gate and drain of the transistor 28, and the drain thereof connected to the gate and drain of the transistor 22. In this configuration, the transistor 30 will allow a bias current proportional to the bias voltage V_{NB} to flow through the transistors 20 and 22 of the reference voltage portion 12.

In operation, a shift in the voltage at the emitter of the transistor 20 caused by a shift in the positive supply V_{DD} relative to the negative supply V_{SS} will be reflected by the transistors 22 and 24 as a corresponding shift in the voltage across the resistor 26. With a constant applied voltage, the current provided by the resistor 26 will remain constant even in the presence of significant shifts in the positive supply V_{DD} . So long as the current provided by the resistor 26 remains constant, the bias voltage V_{NB} developed by the transistor 28 tends to remain constant relative to the negative supply V_{SS} , even in the presence of significant shifts in the voltage thereof. Thus, the bias voltage V_{NB} , although referenced to the V_{BE} of the transistor 20, remains substantially independent of shifts in the supply voltages V_{DD} and V_{SS} .

In some applications, it may be desirable to provide a P-channel bias voltage V_{PB} , as a counterpart for the N-channel bias voltage V_{NB} . In the illustrated embodiment, this is accomplished using a second bias current portion 18' and a second bias voltage portion 16'. In the second bias current portion 18', an N-channel MOS transistor 32 has the source thereof connected to the negative supply V_{SS} , the gate thereof connected to the gate and drain of the transistor 28 of the bias voltage portion 16, and the drain thereof connected to the second bias voltage portion 16'. In the second bias voltage portion 16', a P-channel MOS transistor 34 has the gate and drain thereof connected to the drain of the transistor 32, and the source thereof connected to the positive supply V_{DD} . In this configuration, the transistor 32 will allow a bias current proportional to the N-channel bias voltage V_{NB} to flow through the transistor 34. In response to the bias current, the diode-connected transistor 34 develops a gate to source voltage V_{GS} which is proportional to the bias current, but referenced to the positive supply V_{DD} rather than the negative supply V_{SS} . This voltage, indicated as V_{PB} , is suitable for biasing other P-channel MOS transistors used as constant current sources.

Upon initial application of power, the bias current reference circuit 10 may assume either an inactive or an active state. For example, if no current flows through the reference voltage portion 12 during power-up, no reference voltage will be developed for application to the reference current portion 14. Thus, no reference current will be provided by the reference current portion 14. Without reference current, the bias voltage portion 16 will be unable to establish the bias voltage V_{NB} and enable the bias current portion 18 to direct bias current through the reference voltage portion 12. The bias current reference circuit 10 will therefore remain in the inactive state.

In the illustrated embodiment, however, a start-up portion 36 is provided to allow start-up current to flow through the reference voltage portion 12 when the P-channel bias voltage V_{PB} with respect to the positive supply V_{DD} is less than a predetermined threshold. In the start-up portion 36, a P-channel MOS transistor 38 has the source thereof connected to the positive supply V_{DD} and the gate thereof connected to the gate and drain of the transistor 34 of the second bias voltage portion 16'. The drain of the transistor 38 is connected to the source of a P-channel MOS transistor 40 which has the gate and drain thereof connected to the negative supply V_{SS} . The drain of the transistor 38 is also connected to the gate of a P-channel MOS transistor 42 which has the source thereof connected to the gate and drain of the transistor 22, and the drain thereof connected to the negative supply V_{SS} . In this configuration, the transistor 38 provides bias current for the diode-connected transistor 40 only when the P-channel bias voltage V_{PB} applied to the gate of the transistor 38 is at least one V_{GS} below the positive supply V_{DD} . By constructing the transistor 40 to have a smaller ratio of channel width to channel length than the transistor 38 and thus a higher current density, the gate to source voltage V_{GS} of the transistor 40 will be relatively high when the transistor 38 is turned on. Thus, the transistor 42 will be turned on only when the transistor 38 is turned off, i.e. when the bias current reference circuit 10 is in the passive state. When the transistor 42 turns on, the voltage on the gate and drain of the transistor 22 of the reference voltage portion 12 is pulled toward the negative supply V_{SS} .

When the transistor 42 has pulled the voltage on the gate of the transistor 22 one V_{GS} below the V_{BE} of the transistor 20, start-up current begins to flow through the transistors 20 and 22. Simultaneously, the transistor 24 of the reference current portion 14 will turn on, allowing reference current to flow to the transistor 28 of the bias voltage portion 16. The transistor 28, being connected as a diode, establishes the N-channel bias voltage V_{NB} one V_{GS} above the negative supply V_{SS} . Simultaneously, the transistor 30 assumes the task of directing the flow of bias current through the reference voltage portion 12 by maintaining the transistors 20 and 22 in the forward-biased condition. The bias current reference circuit 10 will thereafter remain in the active state.

With the N-channel bias voltage V_{NB} established, the transistor 32 provides a path for current to flow through the transistor 34. The transistor 34, being diode-connected, establishes the P-channel bias voltage V_{PB} one V_{GS} below the positive supply V_{DD} . Simultaneously, the transistor 38 turns the transistor 42 off by pulling the gate thereof toward the positive supply V_{DD} . Thus, the start-up portion 36 becomes inactive once the bias current reference circuit 10 assumes the active state. On the other hand, the start-up portion 36 automatically becomes active if, for

any reason, the bias current reference circuit 10 should try to return to the inactive state.

Claims

1. A bias current reference circuit comprising:
reference voltage means (12) for providing a reference voltage proportional to a bias current;
reference current means (14) coupled to reference voltage means (12), for providing a reference current proportional to the reference voltage;

bias voltage means (16) coupled to the reference current means (14), for providing a bias voltage (V_{NB}) proportional to the reference current; and

bias current means (18) coupled to the bias voltage means (16) and to the reference voltage means (12), for providing the bias current proportional to the bias voltage for said reference voltage means (12) characterised in that the reference voltage means (12) comprises a bipolar transistor (20) having a base and collector thereof coupled together to a power supply voltage (V_{DD}) and an MOS transistor (22) having the source thereof coupled to the emitter of the bipolar transistor (20).

2. The bias current reference circuit of claim 1 further comprising:

second bias current means (32) coupled to the bias voltage means (16), for providing a second bias current proportional to the bias voltage (V_{NB}).

3. The bias current reference circuit of claim 2 wherein the second bias current means comprises a second MOS transistor (32) having the bias voltage coupled to the gate thereof, said second transistor (32) providing said second bias current.

4. The bias current reference circuit of claim 2 further comprising:

second bias voltage means (34) coupled to the second bias current means (32), for providing a second bias voltage (V_{PB}) proportional to the second bias current.

5. The bias current reference circuit of claim 4 wherein the second bias voltage means comprises a diode-connected third MOS transistor (34) having the second bias current means (32) coupled thereto, said third transistor developing the second bias voltage on the gate thereof.

6. The bias current reference circuit of claim 4 further comprising:

start-up means (36) coupled to the reference voltage means (12) and to the second bias voltage means (34), for providing the bias current for said reference voltage means (12) in response to the second bias voltage V_{PB} being less than a predetermined threshold.

Revendications

1. Circuit de référence de courant de polarisation comprenant:

un moyen de tension de référence (12) qui

produit une tension de référence proportionnelle à un courant de polarisation;

un moyen de courant de référence (14) couplé au moyen de tension de référence (12), afin de produire un courant de référence proportionnel à la tension de référence;

un moyen de tension de polarisation (16) couplé au moyen de courant de référence (14), afin de produire une tension de polarisation (V_{NB}) proportionnelle au courant de référence; et

un moyen de courant de polarisation (18) couplé au moyen de tension de polarisation (16) et au moyen de tension de référence (12), afin de produire le courant de polarisation proportionnellement à la tension de polarisation pour ledit moyen de tension de référence (12), caractérisé en ce que le moyen de tension de référence (12) comprend un transistor bipolaire (20) dont la base et le collecteur sont couplés ensemble à une alimentation en tension électrique (V_{DD}) et un transistor MOS (22) dont la source est connectée à l'émetteur du transistor bipolaire (20).

2. Circuit de référence de courant de polarisation selon la revendication 1, comprenant en outre:

un deuxième moyen de courant de polarisation (32) couplé au moyen de tension de polarisation (16), afin de produire un deuxième courant de polarisation proportionnel à la tension de polarisation (V_{NB}).

3. Circuit de référence de courant de polarisation selon la revendication 2, où le deuxième moyen de courant de polarisation comprend un deuxième transistor MOS (32) dont la grille reçoit la tension de polarisation, ledit deuxième transistor (32) produisant ledit deuxième courant de polarisation.

4. Circuit de référence de courant de polarisation selon la revendication 2, comprenant en outre:

un deuxième moyen de tension de polarisation (34) couplé au deuxième moyen de courant de polarisation (32), afin de produire une deuxième tension de polarisation (V_{PB}) proportionnelle au deuxième courant de polarisation.

5. Circuit de référence de courant de polarisation selon la revendication 4, où le deuxième moyen de tension de polarisation comprend un troisième transistor MOS connecté en diode (34) auquel est couplé le deuxième moyen de courant de polarisation (32), ledit troisième transistor créant sur sa grille la deuxième tension de polarisation.

6. Circuit de référence de courant de polarisation selon la revendication 4, comprenant en outre:

un moyen de mise en marche (36) couplé au moyen de tension de référence (12) et au deuxième moyen de tension de polarisation (34), afin de produire le courant de polarisation pour ledit moyen de tension de référence (12) en réponse au fait que la deuxième tension de polarisation V_{PB} est inférieure à un seuil prédéterminé.

any reason, the bias current reference circuit 10 should try to return to the inactive state.

Claims

1. A bias current reference circuit comprising:
reference voltage means (12) for providing a reference voltage proportional to a bias current;
reference current means (14) coupled to reference voltage means (12), for providing a reference current proportional to the reference voltage;

bias voltage means (16) coupled to the reference current means (14), for providing a bias voltage (V_{NB}) proportional to the reference current; and

bias current means (18) coupled to the bias voltage means (16) and to the reference voltage means (12), for providing the bias current proportional to the bias voltage for said reference voltage means (12) characterised in that the reference voltage means (12) comprises a bipolar transistor (20) having a base and collector thereof coupled together to a power supply voltage (V_{DD}) and an MOS transistor (22) having the source thereof coupled to the emitter of the bipolar transistor (20).

2. The bias current reference circuit of claim 1 further comprising:

second bias current means (32) coupled to the bias voltage means (16), for providing a second bias current proportional to the bias voltage (V_{NB}).

3. The bias current reference circuit of claim 2 wherein the second bias current means comprises a second MOS transistor (32) having the bias voltage coupled to the gate thereof, said second transistor (32) providing said second bias current.

4. The bias current reference circuit of claim 2 further comprising:

second bias voltage means (34) coupled to the second bias current means (32), for providing a second bias voltage (V_{PB}) proportional to the second bias current.

5. The bias current reference circuit of claim 4 wherein the second bias voltage means comprises a diode-connected third MOS transistor (34) having the second bias current means (32) coupled thereto, said third transistor developing the second bias voltage on the gate thereof.

6. The bias current reference circuit of claim 4 further comprising:

start-up means (36) coupled to the reference voltage means (12) and to the second bias voltage means (34), for providing the bias current for said reference voltage means (12) in response to the second bias voltage V_{PB} being less than a predetermined threshold.

Revendications

1. Circuit de référence de courant de polarisation comprenant:

un moyen de tension de référence (12) qui

produit une tension de référence proportionnelle à un courant de polarisation;

un moyen de courant de référence (14) couplé au moyen de tension de référence (12), afin de produire un courant de référence proportionnel à la tension de référence;

un moyen de tension de polarisation (16) couplé au moyen de courant de référence (14), afin de produire une tension de polarisation (V_{NB}) proportionnelle au courant de référence; et

un moyen de courant de polarisation (18) couplé au moyen de tension de polarisation (16) et au moyen de tension de référence (12), afin de produire le courant de polarisation proportionnellement à la tension de polarisation pour ledit moyen de tension de référence (12), caractérisé en ce que le moyen de tension de référence (12) comprend un transistor bijonction (20) dont la base et le collecteur sont couplés ensemble à une alimentation en tension électrique (V_{DD}) et un transistor MOS (22) dont la source est connectée à l'émetteur du transistor bijonction (20).

2. Circuit de référence de courant de polarisation selon la revendication 1, comprenant en outre:

un deuxième moyen de courant de polarisation (32) couplé au moyen de tension de polarisation (16), afin de produire un deuxième courant de polarisation proportionnel à la tension de polarisation (V_{NB}).

3. Circuit de référence de courant de polarisation selon la revendication 2, où le deuxième moyen de courant de polarisation comprend un deuxième transistor MOS (32) dont la grille reçoit la tension de polarisation, ledit deuxième transistor (32) produisant ledit deuxième courant de polarisation.

4. Circuit de référence de courant de polarisation selon la revendication 2, comprenant en outre:

un deuxième moyen de tension de polarisation (34) couplé au deuxième moyen de courant de polarisation (32), afin de produire une deuxième tension de polarisation (V_{PB}) proportionnelle au deuxième courant de polarisation.

5. Circuit de référence de courant de polarisation selon la revendication 4, où le deuxième moyen de tension de polarisation comprend un troisième transistor MOS connecté en diode (34) auquel est couplé le deuxième moyen de courant de polarisation (32), ledit troisième transistor créant sur sa grille la deuxième tension de polarisation.

6. Circuit de référence de courant de polarisation selon la revendication 4, comprenant en outre:

un moyen de mise en marche (36) couplé au moyen de tension de référence (12) et au deuxième moyen de tension de polarisation (34), afin de produire le courant de polarisation pour ledit moyen de tension de référence (12) en réponse au fait que la deuxième tension de polarisation V_{PB} est inférieure à un seuil prédéterminé.

Patentansprüche

1. Polarisationsstromreferenzkreis, enthaltend:
eine Referenzspannungseinrichtung (12) zum Bereitstellen einer einem Polarisationsstrom proportionalen Referenzspannung;
eine Referenzstromeinrichtung (14), die mit der Referenzspannungseinrichtung (12) verbunden ist, um einen Referenzstrom bereitzustellen, der proportional der Referenzspannung ist;
eine Polarisationsspannungseinrichtung (16), die mit der Referenzstromeinrichtung (14) verbunden ist, um eine Polarisationsspannung (V_{NB}) bereitzustellen, die proportional dem Referenzstrom ist; und
eine Polarisationsstromeinrichtung (18), die mit der Polarisationsspannungseinrichtung (16) und der Referenzspannungseinrichtung (12) verbunden ist, um den Polarisationsstrom für die Referenzspannungseinrichtung (12) bereitzustellen, der proportional der Polarisationsspannung ist, dadurch gekennzeichnet, daß die Referenzspannungseinrichtung (12) enthält:
einen bipolaren Transistor (20), dessen Basis und Kollektor zusammen mit einer Versorgungsspannung (V_{DD}) verbunden sind, und einen MOS-Transistor (22), dessen Source-Elektrode mit dem Emitter des bipolaren Transistors (20) verbunden ist.
2. Polarisationsstromreferenzkreis nach Anspruch 1, weiterhin enthaltend:
eine zweite Polarisationsstromeinrichtung (32), die mit der Polarisationsspannungseinrichtung (16) verbunden ist, um einen zweiten

Polarisationsstrom bereitzustellen, der proportional der Polarisationsspannung (V_{NB}) ist.

3. Polarisationsstromreferenzkreis nach Anspruch 2, bei dem die zweite Polarisationsstromeinrichtung einen zweiten MOS-Transistor (32) enthält, dessen Gate-Elektrode mit der Polarisationsspannung verbunden ist, wobei der zweite Transistor (32) den zweiten Polarisationsstrom liefert.

4. Polarisationsstromreferenzkreis nach Anspruch 2, weiterhin enthaltend:
eine zweite Polarisationsspannungseinrichtung (34), die mit der zweiten Polarisationsstromeinrichtung (32) verbunden ist, um eine zweite Polarisationsspannung (V_{PB}) zu liefern, die proportional dem zweiten Polarisationsstrom ist.

5. Polarisationsstromreferenzkreis nach Anspruch 4, bei dem die zweite Polarisationsspannungseinrichtung einen zu einer Diode geschalteten dritten MOS-Transistor (34) enthält, mit dem die zweite Polarisationsstromeinrichtung (32) verbunden ist, wobei der dritte Transistor die zweite Polarisationsspannung an seiner Gate-Elektrode entwickelt.

6. Polarisationsstromreferenzkreis nach Anspruch 4, weiterhin enthaltend:
eine Anlaßeinrichtung (36), die mit der Referenzspannungseinrichtung (12) und der zweiten Polarisationsspannungseinrichtung (34) verbunden ist, um den Polarisationsstrom für die genannte Referenzspannungseinrichtung (12) in Abhängigkeit davon zu liefern, daß die zweite Polarisationsspannung (V_{PB}) niedriger als ein vorbestimmter Schwellenwert ist.
