

Description

The present invention relates generally to form-fill-seal machines and, more particularly, to certain new and useful improvements in the manufacture of such machines in an unusually compact size capable of producing sealed cups and other sealed package structures with increased efficiency.

"Form-fill-seal" is the generic name for a type of machine in which a first thermoformable plastics web is indexed (in most cases, intermittently) to a heating station where the web is brought to forming temperature and then indexed to a forming station where the heated plastics web is drawn by vacuum or pressed by air pressure, or both, either over or into one or more forming dies thereby to form the web into the desired configuration, usually a cup-like cavity.

During the time of forming at the forming station, the web is normally clamped continuously about the periphery of each forming die. Also, the forming dies typically are retractably mounted so that, once the desired formation is made in the web, the die retracts and the formed web is then able to advance to a filling station, which delivers a discrete predetermined amount of product into each cup-like formation.

Simultaneous with the formation and filling of the aforesaid first web, a second web, usually in an upper position and printed, either in a continuous pattern, which requires no registration, or in a design which must be in accurate registration with the bottom web formation so that a complete single pattern or design, will be located over each cup or other formation in the first web.

The second upper web, by means of various rollers, is brought into parallel proximity with the formed and filled lower web and then indexed simultaneously in printed register therewith, where necessary, to a sealing station. At the sealing station, retractable heated sealing dies clamp and seal the lower formed and filled web to the upper web and then withdraw to permit further indexing of the sealed packages to a final station where the individual packages are separated and delivered to a packing or loading station.

In general, previously known form-fill-seal machines for packages are large, unwieldy, and extremely expensive. For example, a widely used machine for producing plastics cups of butter, margarine and the like is approximately 25 ft. (7.62 m) long and costs in the neighbourhood of \$400-\$500 Thousand (U.S.), yet only produces on the order of 500 cups per minute of 5-gram size.

It is therefore an object of this invention to provide a new and improved machine for automatically producing filled and sealed cups or other package structures.

Another object of this invention is to provide a new and improved machine for automatically producing filled and sealed cups or other package structures,

which is more compact in size and produces package structures more efficiently than previously known machines.

Another object of this invention is to provide a new and improved machine for automatically producing filled and sealed cups or other package structures, which is cheaper to manufacture than previously known machines and yet has approximately equal production capabilities.

Accordingly there is provided a machine for automatically simultaneously producing a predetermined number of filled and sealed finished packages, including:

pneumatically driven adjustable indexing drive means for driving a main shaft member;

sprocket means mounted to said main shaft for engaging and adapted intermittently to advance and rest a pair of web transporting roller chains in response to movement of said main shaft, said web transporting roller chains including a series of upstanding pin members;

rotary impaler cylinder means driven by said roller chains;

roller means for transporting a bottom thermoformable web material from a supply roll to said impaler cylinder, said impaler cylinder impaling each of the opposed longitudinal edges of said bottom web onto said roller chain pin members;

means for intermittently indexing said bottom web material to a heating station for heating said web to thermoformability;

means for intermittently indexing said heated web to a forming station, said forming station including retractable forming die means for forming a series of cup-like pockets in said bottom web;

means for intermittently indexing the formed bottom web to a filler station, said filler station including means for filling each of said cup-like pockets with an equal amount of a product supplied to said filler station;

driven roller means for simultaneously advancing a thermoformable top web material in timed sequence with the intermittent advance, forming and filling of said bottom web member, said top web driven roller means transporting said top web into substantially parallel closely adjacent proximity to said bottom web after the cup-like pockets formed therein are filled;

means for intermittently indexing both said bottom web and said top web together to a sealing station, said sealing station including retractable heat sealing die and clamping means for heat sealing the top and bottom webs together;

means for intermittently indexing said sealed top and bottom web members to a punch station, said station including a series of punch dies which punch rounded openings in the sealed web members at the location of the corners of the individual packages to be formed;

means for intermittently indexing and pulling said sealed top and bottom web members to a longitudinal cutting station wherein knife means slit said top and bottom web members along first opposed sides of said cup-like pockets and adjacent the pin engaging edge portions of said bottom web;

transverse cutting means for slitting said top and bottom web members along second opposed side of said cup-like pockets thereby to separate the individual finished packages from one another.

means for transporting said finished packages away from said machine; and

take up roller means for removing the bottom web trim from said roller chain pins.

The invention consists in the novel parts, constructions, arrangements, combinations, steps and improvements herein shown and described.

The accompanying drawings, referred to herein and constituting a part thereof, illustrate preferred embodiments of the invention, and together with the description, serve to explain the principles of the invention. In the drawings:

Figure 1 is a side elevation, partly schematic, of a form-fill-seal machine construction embodying the present invention capable of producing a sealed package structure having a fault line extending across a stress concentrating protrusion member formed in the top surface of the package; Figure 2 is an enlarged fragmentary view in side elevation, partly sectional, illustrating the bottom web heating and vacuum and air pressure forming means forming cup-like cavities in the bottom web member;

Figure 3 is a top plan taken along line 3-3 of Figure 1, illustrating the pin chain drive, female forming dies and formed and filled bottom web cup-like configurations, the view further illustrating a multiple of four package configurations being formed simultaneously in the bottom web, each package having a double-cup cavity configuration;

Figure 4 is an end elevational view, partly sectional, taken along line 4-4 of Figure 1, illustrating the female forming dies and vacuum and air pressure platens for forming the double cup-like configurations in the bottom web;

Figure 5 is an enlarged view in side elevation, partly sectional, of the filler mechanism for depositing a desired flowable substance in equal amounts into each cup-like cavity formed in the bottom web;

Figure 6 is a top plan, partly sectional, taken along line 6-6 of Figure 5, illustrating the product entry ports of the filler bar;

Figure 7 is a sectional view taken along line 7-7 of Figure 5, illustrating the product exit ports of the filler bar;

Figure 8 is an enlarged fragmentary view in side

elevation, illustrating the top web supply, fault line scoring knife and micrometer adjusting means for locating the depth of the knife score, shown in Figure 1;

Figure 9 is a fragmentary bottom plan taken along line 9-9 of Figure 8, illustrating a multiple of four scoring knives simultaneously forming a fault line for each sealed package being produced;

Figure 10 is an enlarged fragmentary view in side elevation, partly sectional, illustrating the differential and constant drive rollers drawing the top web material past the stress concentrator heating and forming means and into register with the formed and filled bottom web cup-like cavities, the top and bottom heat sealing unit sealing the top web onto the bottom web, the punch die which punches the web at the corner locations for the individual packages, and the photoelectric eye which scans registration of the top and bottom web and transmits a signal to the differential drive roller control for correcting register error;

Figure 11 is an enlarged fragmentary view taken along line 11-11 of Figure 10, illustrating the stress concentrator forming dies;

Figure 12 is an enlarged fragmentary view taken along line 12-12 of Figure 10, illustrating the punch openings, stress concentrator locations and fault lines formed in the top web member;

Figure 13 is an enlarged fragmentary view in side elevation, partly sectional and partly schematic of the indexer drive of Figure 1, the view also showing the longitudinal and transverse cutters for separating the individual finished packages, an inclined ramp for receiving the finished packages and the take up roll for the trim waste;

Figure 14 is an end elevation taken along line 14-14 of Figure 13, illustrating the transverse cutting blades separating the individual sealed packages;

Figure 15 is a top plan view taken along line 15-15 of Figure 13;

Figure 16 is a perspective view of a finished package produced by the machine construction shown in Figures 1-15, and

Figure 17 is a perspective view of an alternate embodiment of the package structure of Figure 16 which may be produced by an alternate embodiment of the machine construction of Figures 1-15.

Figures 1-16 illustrate a preferred embodiment of a form-fill-seal machine constructed in accordance with the present invention. In this embodiment, the machine is advantageously adapted for simultaneously forming, filling and sealing four sealed packages, in the configuration of the dispenser package described in Redmond et al U.S. Patent Nos. 4,493,574 and 4,611,715, the disclosures of which are hereby incorporated by reference.

While the apparatus as here embodied is particu-

larly adapted to and was designed for use in the production of the dispenser package structures disclosed in the above mentioned U.S. Patents, the principles underlying the operation of the present invention are not limited to such usage. However, since the invention is particularly adaptable to such usage, reference will be made hereinafter thereto in order to provide an example of a practical and useful embodiment of the invention.

It will also be understood that the invention is not limited to the simultaneous production of four packages, but may be readily adapted to the simultaneous production of more or less packages as desired. Further, while the present invention is not limited to the production of any particular size package, it is particularly well suited for the production of relatively small packages, containing on the order of a few grams to of the order of 4 oz. (0.1134 kg) of product.

Turning now to the drawings, it will be seen that a bottom thermoformable plastics web 21 is indexed intermittently to a heating station 22 where it is brought to forming temperature and thereafter indexed to a forming station 25 which has one or more female forming dies 39.

It will be seen that the bottom web 21 is transported (indexed) to the various stations by a pair of "pin" chains 26, which are simply roller chains with a series of sharp pins 40 mounted on them along their entire length. The bottom web 21 is impaled on the pins 40 by an impaling drum 27 along the selvage (edge) on both sides of the bottom web material 21. It will be understood that other alternative means of gripping the bottom web 21 may be used, such as clamping clips mounted on a roller chain, but these are expensive and have not been found to hold any advantage over the use of simple pins which have been found to grip the web securely.

At the forming station 25, either a vacuum 31 is drawn through very small holes in the female dies 29, which draws the heated plastics web into the configuration of the female dies, or alternatively, air pressure 42 may be applied from above the web to press the heated web into the die configuration. Also, as a further alternative, a combination of pressure and vacuum may be used.

During the time of forming, the web is normally clamped continuously about the periphery of each female die 39. This female die 39 is kept cool by either air or liquid coolant. If desired, the clamping mechanism 28 can also drive a preforming plug into the heated plastics material to assist and control the web thickness after forming by a variety of means. For example, such a plug may be heated or cooled, and may be made of a variety of materials, ranging from aluminium to Teflon plastics material to achieve a broad range of effects and results.

The forming dies 39 and clamping mechanism 28 are retractably mounted, and once the cup-like pocket

formations 43 are formed in the bottom web, the die 39 retracts downwardly while the clamping mechanism 28 rises, enabling the formed web to advance to a filling station 29, where the filler mechanism delivers a predetermined amount of product into each cup-like pocket formation 43.

Simultaneous with the formation and filling of the bottom web 21 an upper web 44, usually printed, either in a continuous pattern which requires no registration or in design which must be accurately registered to the bottom web formation so that a total single pattern or design will be located on each individual package being produced. As more fully described hereinafter, the machine as here preferably embodied, has the capability of producing such registered location of print design when a thermoformable plastics upper web material is used, although it can operate equally well with continuous pattern designs. The upper web is brought, by means of a differential drive roller 31 and a constant drive roller 32, into parallel proximity with the now formed and filled bottom web. It is then indexed simultaneously with the bottom web, in printed register, where necessary, to a sealing station 33. This sealing station by means of heated sealing dies 45 and a clamp mechanism seals the lower formed and filled web to the upper web again by retractable heated sealing dies which withdraw to permit further indexing of the sealed packages.

To separate the individual packages, longitudinal cutting means 34 preferably comprised of sharpened tungsten carbide blades, slit the package from the pin chain as well as between the packages longitudinally. In addition to the pin chain, a set of upper and lower driven draw rollers 35, 36 are mounted so as to pull the web through the slitting blades. The packages are then indexed to a final station 37 where they are chopped off crosswise by guillotine type knife blades. In order to create rounded or beveled corners on the packages after the longitudinal and transverse slitting operations, a die punching station 38 (Fig. 10) is preferably located in the index sequence just before the first slitting takes place after the upper and lower webs are sealed. Alternatively, if just the lower web is desired to be punched, the punch die could be located at an earlier station, either before or after forming but before the filling station (29).

A machine as here embodied has been constructed on the order of 60" (1.524 m) long, as compared to the previously mentioned approximately 25 foot (7.62 m) long commercial machine, and yet has the same or a somewhat higher output and can be manufactured to sell for less than one-half the price of the aforesaid machine.

A key feature and reason behind the unexpected small size and efficient operation of the machine of this invention is believed to be that a basic physics concept has been overlooked in the development of the prior machine, namely, the formula for inertia, MV^2

(Mass times Velocity squared). Thus, the aforesaid prior machine makes 30 cups per cycle in a 5 x 6 configuration while the present machine has a configuration of 10 x 2, or 20 cups per cycle. The essence of the cycling rates is the V^2 factor (velocity squared). Running the 10 x 2 configuration at 30 to 40 cycles per minute, $2 \times 1\frac{1}{2} = 2\frac{1}{2}$ " (63.5 mm) ($2\frac{1}{2}$ inches (63.5 mm) per cycle) is much easier than moving $7\frac{1}{2}$ " (190.5 mm) per cycle:

$$\begin{aligned}(7\frac{1}{2})^2 &= 56.25 \\ (2\frac{1}{2})^2 &= 6.25\end{aligned}$$

It becomes clear that the acceleration/deceleration forces for a $7\frac{1}{2}$ " (190.5 mm) index is 9 times greater than for a $2\frac{1}{2}$ " (63.5 mm) index. Much greater power input, much heavier construction, and much greater breaking force all contribute to operating inefficiency.

If the portion of cycling movement time is 33% of the entire cycle, then

$$1/3 \times 9 = 3$$

Thus, mechanical efficiency on this phase alone of the entire machine is 3:1. If 20 cups are produced at 3 times the efficiency that 30 cups are produced, 60 cups are, in effect, produced on the small machine for every 30 cups produced on the large machine, with the attendant savings. Add to this other similar savings throughout the machine and it will be seen that significant size and cost reductions can be made (certainly at least 50%).

Referring now to certain specifics of the machine as here illustrated and preferably embodied, the bottom forming web 21 generally ranges from 4-8 mils (101.6 - 203.2 μ m) in thickness, depending on the desired size of the package, depth of draw, desired barrier qualities, etc. The materials from which this web can be made may range for example from simple polystyrene, polypropylene, polyvinylchlorides or polyesters, to multilayer coextrusions. This web is threaded over the pin impaler roller 27 and as the machine is indexed, this bottom forming web 21 is impaled along both its edges onto the two indexing pin chains 26. These chains index forward in precise increments, controlled by an indexing drive 46 (Fig. 13) and the illustrated unique positive chain locating system.

The bottom web 21 is first indexed under the radiant or contact heating station 22 where it is brought to forming temperature. It is then indexed forward to a forming station 25 where it is clamped and, where necessary or desirable, plugged, while either air pressure or vacuum or both are applied to the heated web to force it into the cooled female die 39 to achieve the desired formation. The formed web is then indexed to a filling station 29 where flowable product is filled into the formed cavities.

As best seen in Figures 8-10, while the bottom web 21 is being formed and filled, the top web 44 is being drawn by a pair of pull rollers and indexed simultaneously by the same drive means that indexes the

lower web. The upper web is drawn from a supply roll 47 after which it passes over a hard roller directly opposing this roller, where there are a series of very sharp hard blades 48 each independently mounted on a micrometer controlled member 49. The purpose of these blades is to score the heavier top plastics web 44 creating a fault line 50.

The aforesaid pair of draw rollers is connected to the main drive through a differential drive system which can slow or increase the amount of top web movement (which is the printed web) in response to a signal from a photoelectric cell 51 which reads a printed spot on the top web to tell whether the print is in register. The upper drive rollers are located so as to draw the top web 44 from the roll through the fault line blades 48 and feed it vertically downwardly to a second draw roller system advantageously approximately 12 inches (0.3048 m) below.

Located in the gap between the two draw roller systems is a radiant heater 52 as well as a horizontal series of diamond-shaped contact heaters 53. The centre of each diamond heater is in line with the fault lines, followed one index below by a horizontal row of pyramidally-shaped punches and dies 54. When the web is indexed by the two sets of draw rollers, the diamond heaters 53, which have a properly preset temperature, are compressed against the top web 44 causing a series of horizontal diamond shaped formable areas on the upper web. At the next index, the pyramidal punch presses these formable diamond areas into the female dies creating a horizontal line 50 of small pyramidal-shaped formations 56, with the fault line passing through their centre. The lower draw roller system has relief areas so that these raised pyramidal protrusions can pass through them without being crushed. As the top web passes through the lower draw roller system, it is transported around the lower roller and travels horizontally above the lower web with its pyramids in register with the bottom web cup-like pocket formations 43.

The top and bottom webs are thereafter indexed to a sealing station 45 (Fig. 10), comprised of a heated lower sealing die which moves vertically to compress the lower web to the upper web. As the lower web sealing die rises, an upper pressure pad descends and both webs are compressed, heated and sealed between these two pads and the lower sealing die retracts to permit the now formed, filled and sealed stress concentrator package to advance to the punch station 38.

At the punch station 38 a series of hard steel punches and dies advantageously punch a "star"-shaped hole in the web (see Fig. 12) at the locations of the corners of the individual packages, trimming the corners of the packages so that they become round. The star-shaped trim is removed by suitable vacuum means.

At the next station, best shown in Figures 13 and 15, a series of hard sharp blades 34, preferably tung-

sten carbide, slit the individual packages apart into long strips, and a pair of upper and lower auxiliary rollers 35, 36 aid the pin chain in pulling the strip of packages through the blades.

In a final index, a transverse bar 37 containing a series of hard sharp blades (again tungsten carbide) chops through the strips of packages to create a series of individual finished sealed packages 56. There is left on each pin chain 26 a thin strip of plastics material which is rolled up on reels 62 driven by an air motor which slips when the pin chains are at rest or drawn through rollers and chopped into pieces.

The aforesaid machine has a number of other features which give it its extreme flexibility, small size, and economical but high precision construction.

It is completely controlled by a commercially available programmable controller, which is effectively a small computer, such as, for example, that manufactured by the Allen-Bradley company. It is basically a pneumatic machine so that a huge variety of motions and timings may be accomplished by controlling air valves, air pressure, etc. by the programmable controller.

An alternate method of putting precise depth scores (fault lines) over the stress concentrator and eliminating the sharp hard blades, each mounted on a micrometer controller, is to have a controlled heated blade indent the fault line at the position where it transverses the stress concentrator. This method of indenting the fault line has been used on other machines previously and is not of itself claimed as patentable herein.

Also, as here embodied (see Figs 5 to 7) the filler means is unique in that it loads diaphragms 57 which in turn are depressed by pistons (58) loosely fitted into cylinders which are attached to a bar which is driven up and down by an air piston compressing the diaphragms. These diaphragms are attached or clamped to a filler bar 60 on which the air cylinders also are mounted, one for each diaphragm.

The filler bar is bored across its full width to relatively large bores. For ketchup, as an example, the holes are about 1" (25.4 mm) diameter. One bore is the product entry port and the product is delivered to it under pressure. When the diaphragms are fully filled with product, a valve is actuated by the programmable computer, shutting off the pressure. A rotating valve shaft 61, traversing the other bore, is then pivoted approximately 30 degrees, aligning cross-drilled holes in it with the outlet nozzles and with holes drilled in the filler bar. The pistons 58 thereupon collapse and press against the filled diaphragms, forcing the product out of the outlet nozzles and into the cup-like pockets 43 formed in the bottom web. Retraction of the piston 58 thereafter creates suction on the nozzles to prevent drip. The valve shaft 61 which traverses the filler bar is suitably sealed at each end with "O" rings or the like to prevent product leak.

The entire filler assembly is mounted in such a manner that it may be flushed in place for cleaning by raising it and placing a special cleaning cap on the bottom of it to direct flushing water and detergent into an outlet hose and not all over the machine.

The invention in its broader aspects is not limited to the specific embodiments herein shown and described but departures may be made therefrom within the scope of the accompanying claims without departing from the principles of the invention and without sacrificing its chief advantages.

Thus, for example, the top forming system which forms a stress concentrator protrusion member in the top web may be adapted to form any suitable protrusion shape such as, for example, disclosed in U.S. Patents 4,493,574 and 4,611,715. As an alternative to the described integral filler for flowable products, an open station for a commercial filler may be provided which could drop nuts and bolts or other solid products, ranging from candies to machine parts to pills, into the cup-like pockets formed in the bottom web.

Finally, it will be understood that the illustrated machine structure could be readily modified to produce a more conventional cup-like package structure as shown in Figure 17. Such a configuration could be readily produced, for example, by utilizing different web stock and/or thicknesses in the top and bottom supply rolls, modifying the forming die configuration, and eliminating the stress concentrator former.

Claims

1. A machine for automatically simultaneously producing a predetermined number of filled and sealed finished packages, including:

pneumatically driven adjustable indexing drive means (46) for driving a main shaft member;

sprocket means mounted to said main shaft for engaging and adapted intermittently to advance and rest a pair of web transporting roller chains (26) in response to movement of said main shaft, said web transporting roller chains (26) including a series of upstanding pin members (40);

rotary impaler cylinder means (27) driven by said roller chains;

roller means for transporting a bottom thermoformable web material from a supply roll to said impaler cylinder (27), said impaler cylinder impaling each of the opposed longitudinal edges of said bottom web onto said roller chain pin members;

means for intermittently indexing said bottom web material to a heating station (22) for heating said web to thermoformability;

means for intermittently indexing said heated web to a forming station (25), said forming station including retractable forming die means (39) for forming a series of cup-like pockets in said bottom web;

sten carbide, slit the individual packages apart into long strips, and a pair of upper and lower auxiliary rollers 35, 36 aid the pin chain in pulling the strip of packages through the blades.

In a final index, a transverse bar 37 containing a series of hard sharp blades (again tungsten carbide) chops through the strips of packages to create a series of individual finished sealed packages 56. There is left on each pin chain 26 a thin strip of plastics material which is rolled up on reels 62 driven by an air motor which slips when the pin chains are at rest or drawn through rollers and chopped into pieces.

The aforesaid machine has a number of other features which give it its extreme flexibility, small size, and economical but high precision construction.

It is completely controlled by a commercially available programmable controller, which is effectively a small computer, such as, for example, that manufactured by the Allen-Bradley company. It is basically a pneumatic machine so that a huge variety of motions and timings may be accomplished by controlling air valves, air pressure, etc. by the programmable controller.

An alternate method of putting precise depth scores (fault lines) over the stress concentrator and eliminating the sharp hard blades, each mounted on a micrometer controller, is to have a controlled heated blade indent the fault line at the position where it transverses the stress concentrator. This method of indenting the fault line has been used on other machines previously and is not of itself claimed as patentable herein.

Also, as here embodied (see Figs 5 to 7) the filler means is unique in that it loads diaphragms 57 which in turn are depressed by pistons (58) loosely fitted into cylinders which are attached to a bar which is driven up and down by an air piston compressing the diaphragms. These diaphragms are attached or clamped to a filler bar 60 on which the air cylinders also are mounted, one for each diaphragm.

The filler bar is bored across its full width to relatively large bores. For ketchup, as an example, the holes are about 1" (25.4 mm) diameter. One bore is the product entry port and the product is delivered to it under pressure. When the diaphragms are fully filled with product, a valve is actuated by the programmable computer, shutting off the pressure. A rotating valve shaft 61, traversing the other bore, is then pivoted approximately 30 degrees, aligning cross-drilled holes in it with the outlet nozzles and with holes drilled in the filler bar. The pistons 58 thereupon collapse and press against the filled diaphragms, forcing the product out of the outlet nozzles and into the cup-like pockets 43 formed in the bottom web. Retraction of the piston 58 thereafter creates suction on the nozzles to prevent drip. The valve shaft 61 which traverses the filler bar is suitably sealed at each end with "O" rings or the like to prevent product leak.

The entire filler assembly is mounted in such a manner that it may be flushed in place for cleaning by raising it and placing a special cleaning cap on the bottom of it to direct flushing water and detergent into an outlet hose and not all over the machine.

The invention in its broader aspects is not limited to the specific embodiments herein shown and described but departures may be made therefrom within the scope of the accompanying claims without departing from the principles of the invention and without sacrificing its chief advantages.

Thus, for example, the top forming system which forms a stress concentrator protrusion member in the top web may be adapted to form any suitable protrusion shape such as, for example, disclosed in U.S. Patents 4,493,574 and 4,611,715. As an alternative to the described integral filler for flowable products, an open station for a commercial filler may be provided which could drop nuts and bolts or other solid products, ranging from candies to machine parts to pills, into the cup-like pockets formed in the bottom web.

Finally, it will be understood that the illustrated machine structure could be readily modified to produce a more conventional cup-like package structure as shown in Figure 17. Such a configuration could be readily produced, for example, by utilizing different web stock and/or thicknesses in the top and bottom supply rolls, modifying the forming die configuration, and eliminating the stress concentrator former.

Claims

1. A machine for automatically simultaneously producing a predetermined number of filled and sealed finished packages, including:

pneumatically driven adjustable indexing drive means (46) for driving a main shaft member;

sprocket means mounted to said main shaft for engaging and adapted intermittently to advance and rest a pair of web transporting roller chains (26) in response to movement of said main shaft, said web transporting roller chains (26) including a series of upstanding pin members (40);

rotary impaler cylinder means (27) driven by said roller chains;

roller means for transporting a bottom thermoformable web material from a supply roll to said impaler cylinder (27), said impaler cylinder impaling each of the opposed longitudinal edges of said bottom web onto said roller chain pin members;

means for intermittently indexing said bottom web material to a heating station (22) for heating said web to thermoformability;

means for intermittently indexing said heated web to a forming station (25), said forming station including retractable forming die means (39) for forming a series of cup-like pockets in said bottom web;

means for intermittently indexing the formed bottom web to a filler station (29), said filler station including means for filling each of said cup-like pockets with an equal amount of a product supplied to said filler station;

driven roller means for simultaneously advancing a thermoformable top web material (44) in timed sequence with the intermittent advance, forming and filling of said bottom web member (21), said top web driven roller means transporting said top web into substantially parallel closely adjacent proximity to said bottom web after the cup-like pockets formed therein are filled;

means for intermittently indexing both said bottom web and said top web together to a sealing station (45), said sealing station including retractable heat sealing die and clamping means for heat sealing the top and bottom webs together;

means for intermittently indexing said sealed top and bottom web members to a punch station (38), said station including a series of punch dies which punch rounded openings in the sealed web members at the location of the corners of the individual packages to be formed;

means for intermittently indexing and pulling said sealed top and bottom web members to a longitudinal cutting station wherein knife means (34) slit said top and bottom web members (21,44) along first opposed sides of said cup-like pockets and adjacent the pin engaging edge portions of said bottom web;

transverse cutting means (37) for slitting said top and bottom web members along second opposed side of said cup-like pockets thereby to separate the individual finished packages from one another.

means for transporting said finished packages away from said machine; and

take up roller means (62) for removing the bottom web trim from said roller chain pins (40).

2. A machine as claimed in claim 1, including solid state programmable controller means for controlling said indexing drive means (46).

3. A machine as claimed in claim 1 or 2, wherein said forming means includes vacuum means (31) drawing said bottom web material into a female forming die (39) and air pressure means (42) simultaneously pressing said web into said forming die.

4. A machine as claimed in any preceding claim, wherein said top web driven rollers include:

a differential drive roller (31), and

a constant index drive roller (32), and further comprising scoring means (48) adapted to indent said top web with a fault line extending partially through the thickness of said web material and oriented in parallel to the direction of motion of said top web;

said differential drive and constant index rollers transporting said scored top web past heat means and stress concentrator former means (54),

said stress concentrator former means adapted

to form a series of protrusions in said top web member at intervals essentially equal to the index step length thereby to displace said fault line from the surface of said web; and registration scanner means (51) adapted to detect lack of register between said top web and said cup-like pockets formed in said bottom web,

said scanner means including means for sending a control signal to said differential drive means to correct improper register.

5. A machine as claimed in any preceding claim, wherein said filter station (29) is adapted to fill a flowable product into the cup-like pockets formed in said bottom web, said filter station including:

a filler bar (60) comprising:

a series of product exit ports (64) located in registry with each cup-like pocket formed in said bottom web,

each product exit port (64) communicating with an expandible diaphragm chamber and including valve means for closing said communication,

a product entry port (63) communicating with each of said expandible diaphragm chambers,

means introducing product to each of said chambers under pressure,

means shutting off pressure to said product when each of said chambers is full, and

means closing communication between each of said chambers and said exit port (64) when product is being filled into said chamber; and

piston means (58) adapted to depress the diaphragm (57) when full to force the product in each of said chambers out said product exit port.

Patentansprüche

1. Vorrichtung zur automatischen und gleichzeitigen Herstellung einer vorbestimmten Anzahl von gefüllten und versiegelten Fertigpackungen, umfassend:

pneumatisch angetriebene, einstellbare Schaltgetriebemittel (46) zum Antreiben einer Hauptwelle,

auf der Hauptwelle angeordnete einrückbare Zahnelemente, mit Hilfe derer ein Paar von Bahntransportrollenketten (26) in Reaktion auf eine Bewegung der Hauptwelle intermittierend vorwärts bewegt und ruhig gehalten werden können, wobei die Bahntransportrollenketten (26) eine Reihe von nach oben stehenden Stiftelementen (40) aufweisen,

durch die Rollenketten angetriebene rotierende Zylindermittel (27) zum Aufspießen,

Rollensmittel für den Transport eines wärmeformbaren unteren Bahnmaterials von einer Vorratsrolle zu dem Aufspießzylinder (27), wobei der Aufspießzylinder jede der einander entgegengesetzten Längskanten der unteren Bahn auf die Rollenkett-

tenstiftelemente aufspießt,

Mittel zum intermittierenden Zuführen des unteren Bahnmaterials zu einer Heizstation (22) zum Erwärmen der Bahn, bis diese wärmeformbar ist,

Mittel zum intermittierenden Zuführen der erwärmten Bahn zu einer Formgebungsstation (25), wobei diese Formgebungsstation einziehbares Umformgesenkmittel (39) zum Bilden einer Reihe von becherförmigen Taschen in der unteren Bahn aufweist,

Mittel zum intermittierenden Zuführen der umgeformten unteren Bahn zu einer Füllstation (29), wobei diese Füllstation Mittel zum Befüllen jeder der becherförmigen Taschen mit einer gleich großen Menge eines dieser Füllstation zugeführten Produkts aufweist,

angetriebene Rollenmittel für den Vorschub eines wärmeformbaren oberen Bahnmaterials (44) in zeitlich gesteuerter Sequenz mit dem intermittierenden Vorschub, und zum gleichzeitigen Ausformen und Befüllen des unteren Bahnelements (21), wobei die angetriebenen Rollenmittel für die obere Bahn diese obere Bahn in einer im wesentlichen parallelen dicht angrenzenden Nähe zu der unteren Bahn transportieren, nachdem die darin ausgebildeten becherförmigen Taschen befüllt sind,

Mittel zum intermittierenden Zuführen der unteren Bahn zusammen mit der oberen Bahn zu einer Verschleißstation (45), wobei diese Verschleißstation einziehbarer Heißsiegelstempel und Klemmeinrichtungen zum Verbinden der oberen und unteren Bahnen durch Heißsiegeln aufweist, Mittel zum intermittierenden Zuführen der versiegelten oberen und unteren Bahnelemente (21, 44) zu einer Stanzstation (38), wobei diese Station einer Reihe von Stanzmatrizen aufweist, die runde Öffnungen in die versiegelten Bahnelemente an Stellen an den Ecken der einzelnen zu bildenden Packungen einstanzt,

Mittel zum intermittierenden Zuführen und Ziehen der versiegelten oberen und unteren Bahnelemente zu einer Längsschneidstation, in der Messermittel (34) die oberen und unteren Bahnelemente entlang erster entgegengesetzten Seiten der becherförmigen Taschen und nahe der mit den Stiften in Eingriff gebrachten Kantenabschnitte der unteren Bahn einschneiden,

Querschneidmittel (37) zum Einschneiden der oberen und unteren Bahnelemente entlang zweiter entgegengesetzter Seiten der becherförmigen Taschen, um dadurch die einzelnen Fertigpackungen voneinander zu trennen,

Mittel zum Abtransport der Fertigpackungen von der Vorrichtung, und

Aufwickelwalzenmittel (62) zum Entfernen des Randes der unteren Bahn von den Rollenkettenstiften (40).

2. Vorrichtung nach Anspruch 1, die fest programmierbare Steuerungsmittel zum Steuern der Schalt-

getriebemittel (46) umfaßt.

3. Vorrichtung nach Anspruch 1 oder 2, in der die Formgebungsmittel Vakuummittel (31), die das untere Bandmaterial in ein aufnehmendes Umformgesenk (39) ziehen, und Druckluftmittel (42) umfassen, die das Band gleichzeitig in das Umformgesenk drücken.

4. Vorrichtung nach einem der vorhergehenden Ansprüche, in der die angetriebenen Rollen für das obere Band umfassen:

eine Differentialantriebsrolle (31), und

eine Konstantantriebsrolle (32), und desweiteren Kerbschnittmittel (48), mit Hilfe derer in die obere Bahn eine Bruchlinie eingekerbt werden kann, die sich teilweise durch die Dicke des Bahnmaterials erstreckt und parallel zu der Bewegungsrichtung der oberen Bahn ausgerichtet ist,

wobei die Differentialantriebs- und Konstantantriebsrollen die mit der Einkerbung versehene obere Bahn an den Heizmitteln und den Spannungskonzentrationsbildungsmitteln (54) vorbei transportieren,

wobei mit Hilfe der Spannungskonzentrationsbildungsmittel eine Reihe von Vorsprüngen in dem oberen Bahnelement in Abständen, die im wesentlichen den Indexschrittlängen entsprechen, ausgebildet werden können, um so die Bruchlinie von der Oberfläche der Bahn zu verschieben, und Lagegenauigkeitsabtastrmittel (51), mit Hilfe derer eine fehlende Lagegenauigkeit zwischen der oberen Bahn und den in der unteren Bahn ausgebildeten becherförmigen Taschen erfaßt werden kann,

wobei die Abtastrmittel Mittel zum Senden eines Steuersignals an die Differentialantriebsmittel zur Korrektur der unpassenden Lagegenauigkeit umfassen.

5. Vorrichtung nach einem der vorhergehenden Ansprüche, in der mit Hilfe der Füllstation (29) ein fließfähiges Produkt in die in der unteren Bahn ausgebildeten becherförmigen Taschen gefüllt werden kann, wobei die Füllstation umfaßt:

eine Füllereinheit (60) mit

einer Reihe von Produktausgabeöffnungen (64), die sich in Lagegenauigkeit mit jeder der in dem unteren Band ausgebildeten becherförmigen Taschen befinden,

wobei jede Produktausgabeöffnung (64) mit einer ausdehnbaren Membrankammer in Verbindung steht und Ventilmittel zur Unterbrechung dieser Verbindung aufweist,

einer Produkteintrittsöffnung (63), die mit jeder der ausdehnbaren Membrankammern in Verbindung steht,

Mitteln zum Eingeben des Produkts in diese Kammern unter Druckbeaufschlagung,

Mitteln zum Absperren des auf dieses Produkt einwirkenden Druckes, wenn die Kammern gefüllt sind, und mit Mitteln zum Schließen des Verbindungs-

wegs zwischen jeder der Kammern und der Ausgabeöffnung (64), wenn das Produkt in diese Kammern gefüllt ist, und mit Kolbenmitteln (58), mit Hilfe derer die Membran (57) gedrückt werden kann, wenn diese voll ist, um das in den Kammern befindliche Produkt durch die Produktausgabeöffnung hinauszudrücken.

Revendications

1. Une machine pour produire simultanément et automatiquement un nombre prédéterminé d'emballages terminés, remplis et scellés incluant :

des moyens réglables (46) d'entraînement en avance entraînés pneumatiquement pour entraîner un élément servant d'arbre principal ;

des moyens à chaîne montés en liaison d'engagement sur ledit arbre principal et adaptés pour faire avancer de manière intermittente et pour arrêter une paire de chaînes à rouleaux de transfert de bande (26) en réponse au mouvement dudit arbre principal, lesdites chaînes à rouleaux de transfert (26) de bande incluant une série d'éléments formant des pattes verticales (40) ;

des moyens (27) en forme de cylindres crantés rotatifs entraînés par lesdites chaînes à rouleaux ;

des moyens en forme de rouleaux pour transférer une matière thermoformable servant de bande de dessous à partir d'un rouleau d'alimentation vers ledit cylindre cranté (27), ledit cylindre cranté engageant ses crans à travers chacun des bords longitudinaux opposés de ladite bande de dessous sur les éléments constituant des pattes sur ladite chaîne à rouleaux ;

des moyens pour faire avancer de manière intermittente ladite matière servant de bande de dessous vers une station (22) de chauffage pour chauffer ladite bande pour la thermoformer ;

des moyens pour faire avancer de manière intermittente ladite bande chauffée vers une station (25) de formage, ladite station de formage comprenant des moyens (39) en forme de matrices de formage relevables pour former une série de poches en forme de barquettes dans ladite bande de dessous ;

des moyens pour faire avancer de manière intermittente la bande de dessous formée vers une station (29) de remplissage, ladite station de remplissage comprenant des moyens pour remplir chacune des poches en forme de barquettes avec une quantité égale d'un produit fourni à ladite station de remplissage ;

des moyens servant de rouleaux d'entraînement pour faire avancer simultanément une matière (44) thermoformable servant de bande de dessus en séquence synchronisé avec l'avance intermittente, pour former et pour remplir ledit élément en forme de bande de dessus (21), lesdits moyens servant de rouleaux d'entraînement de la bande de dessus transfé-

rant ladite bande de dessus très proche de, et pratiquement parallèlement à, ladite bande de dessous après le remplissage des poches formées en forme de barquettes ;

des moyens pour faire avancer de manière intermittente à la fois ladite bande de dessous et ladite bande de dessus ensemble vers une station de scellage, ladite station (45) de scellage comprenant une matrice de scellage à chauffage pour relevable et des moyens de serrage pour sceller ensemble à chaud les bandes de dessus et de dessous ;

des moyens pour faire avancer de manière intermittente lesdits éléments en forme de bandes de dessus et de dessous scellés vers une station (38) de perforation, ladite station comportant une série de matrices de perforation qui perforent des ouvertures arrondies dans les éléments de bandes scellés au voisinage des coins des emballages individuels à former ;

des moyens pour faire avancer et tirer de manière intermittente lesdits éléments de bandes de dessus et de dessous scellés vers une station de découpe longitudinale dans laquelle des moyens en forme de couteaux (34) fendent lesdits éléments en forme de bande de dessus et de dessous (21, 44) le long de premiers côtés opposés desdites poches en forme de barquettes et au voisinage des parties de bord de ladite bande de dessous qui s'engagent dans les pattes ;

des moyens de découpe transverse (37) pour trancher lesdits élément en forme de bande de dessus et de dessous le long des seconds côtés opposés desdites poches en forme de barquettes de façon à séparer les uns des autres les emballages individuels terminés ;

des moyens pour transférer lesdits emballages terminés loin de ladite machine ; et

des moyens servant de rouleaux de prélèvement (62) pour retirer les restes de la bande de dessous desdites pattes des chaînes à rouleaux (40).

2. Une machine selon la revendication 1, comprenant des moyens servant de contrôleur programmable électronique, pour commander lesdits moyens d'entraînement en avance (46).

3. Une machine selon la revendication 1 ou 2, dans laquelle lesdits moyens de formage comportent des moyens de mise sous vide (31), tirant ladite matière en forme de bande de dessous dans une matrice de formage femelle (39), des moyens d'air sous pression (42) étant prévus pour presser simultanément ladite bande dans ladite matrice de formage.

4. Une machine selon une revendication précédente quelconque, dans laquelle lesdits rouleaux d'entraînement de la bande de dessus comprennent :
un rouleau d'entraînement différentiel (31) et
un rouleau d'entraînement en avance constante (32) et comprenant de plus des moyens (44)

destinés à réaliser des entailles, prévus pour former des indentations dans ladite bande de dessus sur une ligne de défauts s'étendant partiellement à travers l'épaisseur de ladite matière en bande et orientées en parallèle au sens du mouvement de ladite bande de dessus ; 5

lesdits rouleaux d'entraînement différentiel et d'indexation constante transférant ladite bande de dessous entaillée à travers des moyens de chauffage et des moyens servant de conformateur de concentration d'efforts (54) ; 10

lesdits moyens servant de conformateur de concentration d'efforts étant adaptés à former une série de saillies dans ledit élément en forme de bande de dessus à des intervalles essentiellement égaux au pas d'avance en longueur, de façon à déplacer ladite ligne de défauts de la surface de ladite bande ; et 15

des moyens de surveillances de mise en coïncidence (51) adaptés à détecter la perte de coïncidence entre ladite bande de dessus et lesdites poches en forme de barquettes formées dans ladite bande de dessous, lesdits moyens de surveillance comprenant des moyens pour émettre un signal de contrôle vers ledit moyen d'entraînement différentiel pour corriger une coïncidence non convenable. 20 25

5. Une machine selon une revendication précédente quelconque, dans laquelle ladite station de remplissage (29) est destinée à remplir avec un produit fluide les poches en forme de barquettes formées dans ladite bande de dessous, ladite station de remplissage comprenant : 30

une barre de remplissage (60) comportant :

une série d'orifices de sortie de produit (64) disposés en coïncidence avec chacune desdites poches en forme de barquettes formées dans ladite bande de dessous, 35

chaque orifice de sortie de produit (64) communiquant avec une chambre à diaphragme expansible, et comprenant des valves pour fermer ladite communication, 40

un orifice (63) d'entrée de produit communiquant avec chacune desdites chambres à diaphragme expansible,

des moyens pour introduire le produit dans chacune desdites chambres sous pression, 45

des moyens pour annuler la pression sur ledit produit quand chacune desdites chambres est pleine, et

des moyens pour fermer la communication entre chacune desdites chambres et ledit orifice de sortie (64) quand le produit a été rempli dans ladite chambre ; et 50

des moyens en forme de pistons (58) destinés à appuyer sur le diaphragme (57) quand celui-ci est plein pour forcer le produit dans chacune desdites chambres vers l'extérieur desdits orifices de sortie de produit. 55
