

40

Description

This invention relates in general to a lockset and more particularly to a lockset assembly in which the latch bolt is extendable into a dead bolt function.

With the usual latch bolt type lockset, the bolt extends about 12 mm ($\frac{1}{2}$ ") from the front of the lock. Taking into consideration the gap that exists between the door jamb and the door, even less of the length of the latch bolt is available for engagement with the door jamb. Accordingly, with this type of lock, one possible way of obtaining unlawful entry is to spread the door jamb further away from the door to have the latch bolt clear the striker and the lock will not longer serve to maintain the door closed.

In view of the above, it has become increasingly popular to add an auxiliary dead bolt lock to the door. However, the use of such an auxiliary dead bolt does present some problems. For example, its use requires a second hole to be drilled in the door as well as requiring the mounting of an additional mechanism. Also it may require the use of a separate key if the latch bolt cylinder and the auxiliary dead bolt cylinder are not keyed alike. In addition, the latch bolt mechanism as well as the auxiliary dead bolt are normally capable of being locked on the inside. In an emergency situation, it would take two actions by the person in the inside to retract the latch bolt and auxiliary dead bolt to open the door and have egress therefrom.

US Patent No. 4,333,324 describes a spring/dead bolt assembly in which one part of the key-in-knob lock set functions in a normal manner such that when the lock set is unlocked, either the outside or inside knob can be manipulated to open the door by withdrawing the latch bolt from a normal spring latch extended position. When, instead, the lock set is locked, the latch bolt is extended an exceptionally long distance into the frame to a dead bolt position. Extension and retraction of the latch bolt to and from the dead bolt position is accomplished by manipulation of a main cam through the agency of a key in the outside or a turn button on the inside. The features of the pre-characterising part of the present independent claim are known from this document.

In view of the above, it is an object of the present invention to provide an improved lockset assembly which functions both as a latch bolt and a dead bolt.

More specifically, it is an object of the present invention to provide a lockset assembly in which the latch bolt is extendable into a dead bolt position.

Yet another object of the present invention is to provide a lockset assembly in which the latch bolt is movable from a latching position into a dead bolt position and in which a panic release from the inside of the door is provided whereby the bolt can be released or retracted from its dead bolt position merely by turning the hand-operated

mechanism. The present invention provides: A lockset for a door which comprises a latch bolt assembly including a bolt movable between a partially extended latching position, a fully extended dead bolt position, and a retracted position, a spindle extending through said latch bolt assembly in a direction transverse of the direction of movement of said bolt, means connecting said spindle to said bolt for moving said bolt between its positions upon rotation of said spindle, and an operating assembly comprising a hand operator having a locking means therein, a first plate mounted for linear movement in a direction transverse to the axis of said spindle, an actuating member connected to said hand operator for moving said first plate and rotatable drive means attached to said spindle characterised in that said operating assembly further comprises a second plate having linear movement transverse to the axis of said spindle and adapted to be moved by said first plate, so that said actuating member can be locked in a dead bolt position to prevent movement of said latch bolt from said fully extended position to said retracted position and that said rotatable drive means is adapted to be rotated by said second plate.

In a preferred embodiment of the lockset according to the present invention, a lockset includes a lock front which can be mounted on a door having either a bevelled or flat front surface.

In a further preferred embodiment of the lockset of the present invention, the lockset assembly is able to compensate for differences in door thicknesses.

It is further preferred that the latch bolt assembly of the present invention is provided with a wear strip to provide relatively more durable action.

A lockset for a door characterised by a latch bolt assembly comprising:

a bolt movable between a partially extended latching position, a fully extended dead bolt position, and a retracted position,

spring means biasing said bolt toward its dead bolt position,

a spindle extending through said latch assembly in a direction transverse of the direction of movement of said bolt,

means connecting said spindle to said bolt for moving said bolt between its positions upon rotation of said spindle,

means for normally biasing said latch bolt in its latching position, including means for holding said latch bolt in its latching position when said door is open, and

means effective in response to closing of said door when said lockset is in a locked state, to cause the latch bolt to be moved automatically into its dead bolt position, is described and claimed in our co-pending European Patent Application No. 0136891.

The invention will now be further described with reference to the accompanying drawings.

In the accompanying drawings:

Figure 1 is a plan view looking down upon the lockset assembly showing it mounted within the door and its association with the door jamb;

Figure 2 is a horizontal sectional view taken along the horizontal axis of the lockset showing the lockset mounted within a metal door frame;

Figure 3 is a horizontal exploded plan view showing the various subassemblies of the lockset of the present invention;

Figure 4 is a perspective exploded view showing the various subassemblies of the lockset of the present invention;

Figure 5 is a perspective exploded view of the outside actuating assembly of the lockset of the present invention;

Figure 6 is a perspective exploded view of the inside actuating assembly of the lockset of the present invention;

Figure 7 is a view taken along the lines 7-7 of Figure 2 with the rose removed showing the position of the elements of the outside operating cassette when the lockset is in its dead bolt position;

Figure 8 is a view similar to that of Figure 7 but showing the outside cassette with the rack plate removed;

Figure 9 is a view similar to Figure 7 but showing the position of the components of the outside operating cassette when the latch bolt is in the latching position;

Figure 10 is a view similar to that of Figure 7 but showing the position of the components of the outside operating cassette when the latch bolt has been retracted into its open or retracted position by the hand-operated mechanism;

Figure 11 is a view taken along the lines 11-11 of Figure 2 with the rose removed and showing the positions of the components of the elements of the inside cassette when the lockset is in its dead bolt position;

Figure 12 is a transverse sectional view taken along the lines 12-12 of Figure 11;

Figure 13 is a view similar to Figure 11 but showing the components of the inside operating cassette when the latch bolt is in the latching position;

Figure 14 is a view similar to that of Figure 11 but showing the position of the components of the inside operating cassette when the latch bolt has been retracted into its open or retracted position by the hand-operated mechanism;

Figure 15 is a perspective view of the turn button assembly used in connection with the inside operating assembly of the lockset;

Figure 16 is a vertical sectional view taken along the lines 16-16 of Figure 3 and showing the cross-section of the latch bolt assembly with the latch bolt in its dead bolt or fully extended position;

Figure 17 is a view similar to that of Figure 16 but showing the latch bolt in its latching position;

Figure 18 is a view similar to that of Figure 16 but showing the latch bolt in its open or fully retracted position;

Figure 19 is a view taken along the lines 19-19 of Figure 2 and showing the relationship of the turn

button actuator with respect to the pinion extension when the latch bolt is in its dead bolt position;

Figure 20 is a view similar to Figure 19 but showing the relative position of the turn button actuator with respect to the pinion extension when the latch bolt is positioned in its latching position;

Figure 21 is a view similar to Figure 19 but showing the relative position of the turn button actuator with respect to the pinion extension when the latch bolt is in its fully retracted or open position;

Figure 22 is a view taken along the lines 22-22 of Figure 1 showing the mounting of the lock within a metal door frame;

Figure 23 is a vertical cross-sectional view showing the connection of the front of the lock with respect to a metal door;

Figure 24 is a view showing the inside of the front plate looking outwardly therefrom from within the door;

Figure 25 is a horizontal cross-sectional view through the tip of the latch bolt assembly.

Referring to the drawings and in particular Figure 1, the lockset mechanism 1 of the present invention is shown mounted in a door 2 and includes an outside hand-operated member 4 and an inside hand-operated member 6 which in the preferred embodiment are an outside lever 8 and an inside lever 10. The outside and inside levers 8 and 10 are used to retract a latch bolt 12 of the latch bolt assembly 14 of the lockset mechanism from a striker box 16 and striker plate 18 mounted on the door jamb 20 in conventional fashion. According to the embodiment shown herein, the outside operating assembly 27 of the lockset may be provided with a key-operated lock cylinder 22 mounted within the outside lever 8 and the inside operating assembly 44 of the lockset may be provided with a turn button 26 mounted within the inside lever 10. The lock cylinder 22 and turn button 26 may be used to move the latch bolt 12 between its extended dead bolt position shown in full lines in Figure 1 and its latching position shown by the dotted lines in Figure 1.

Referring now to Figures 2, 3, and 4, the outside operating assembly 27 includes the outside lever 8 which is rotatably mounted within an outside rose 28 and includes a generally square-shaped projection 30 extending into the outside rose 28 and is held in place for rotational motion with respect thereto by a retaining ring 31. Positioned within the outside rose 28 is an outside operating cassette 32 having upper and lower ear-like projections 34 and 36 respectively extending therefrom which fit into suitable grooves 38 and 40 respectively on the outer surface of a latch bolt assembly holder 42 which is positioned within the door 2. A generally circular raised portion 43 is provided on the inside surface of the outside rose 28 which extends into a mating circular groove 45 in the outside surface of the outside operating cassette 32 to provide radial alignment of the two members. The latch bolt assembly holder 42

provides a mechanism for mounting the latch bolt assembly 14 which contains the latch bolt 12 and includes a suitable slot 47 into which the latch bolt assembly 14 may be inserted.

In a similar manner, an inside operating assembly 44 includes the inside lever 10 which is pivotally mounted within an inside rose 46 and includes a generally square-shaped projection 48 extending thereinto and which has a retaining ring 50 attached thereto so that the inside lever 10 is mounted for relative rotation with respect to the inside rose 46 in a like manner as the outside operating assembly 27. An inside operating cassette 52 is mounted within the inside rose 46 and includes upper and lower ear-like projections 54 and 56 respectively which extend into the grooves 38 and 40 on the latch bolt assembly holder 42. A generally circular raised portion 57 is provided on the inside surface of the inside rose 46 which extends into a mating circular groove 59 in the outside surface of the inside operating cassette to provide radial alignment of the two members. A spindle 58 extends through the latch bolt assembly 14 and between the inside and outside operating cassettes 32 and 52 in a direction perpendicular to the axis of movement of the latch bolt 12.

Before going into the details of the respective inside and outside operating assemblies 27 and 32 as well as the latch bolt assembly 14, the basic assembly of the lockset within the door 2 will be described. Assuming that the lockset 1 is to be mounted on a metal door 2, such as shown in Figures 1 and 2, and that the proper openings have been provided in the door, the lockset 1 of the present invention may be mounted as follows. It should be noted that although the lockset 1 of the present invention is shown mounted in a left-handed door 2, it is applicable to doors of any configuration.

The outside operating cassette 32 is mounted on the latch bolt assembly holder 42 with the projections 34 and 36 received within the grooves 38 and 40 respectively of the holder 42. A roll pin extends through the lower projection 36 into slot 62 formed in the bottom of the groove 40. This permits the outside operating cassette 32 to have limited relative movement with respect to the latch bolt assembly holder 42 while maintaining the outside operating cassette 32 and the latch bolt holder 42 together as a subassembly. With the outside operating cassette 32 positioned against the surface outside of the door 2 and the latch bolt assembly holder 42 positioned within the frame of the door 2, the latch bolt assembly 14 may be inserted into the latch bolt assembly holder 42 and secured thereto by means of a screw 64. After the spindle 58 is inserted through the latch bolt assembly 14, the inside operating cassette 52 is positioned on the inside surface of the door 2 with its projections 54 and 56 extending into the grooves 38 and 40 on the latch bolt assembly holder 42.

The outside rose 28 to which the outside lever 8 is attached includes upper and lower internally

threaded posts 66 extending in a direction perpendicular to the axis of movement of the latch bolt assembly 14. When the outside rose 28 is mounted over the outside operating cassette 22, the posts 66 extend into openings 68 in the outside operating cassette 32. The inside rose 46 has upper and lower openings 70 therein which align with openings 72 in the inside operating cassette 52 when the inside rose 46 is mounted thereon. Screw members 74 extend through the openings 70, 72 in the inside rose 42 and the inside operating cassette 48 into threaded engagement with the posts 66 on the outside rose 28.

As it is typical in the art, the lever portion 75 of each of the lever handles 8 and 10 extends horizontally in a direction opposite to the extension of the latch bolt 12. As the inside and outside operating cassettes 32 and 52 are moveable relative to the latch bolt assembly holder 42 in a direction perpendicular to the axis of the latch bolt assembly 14, the lockset 1 will mount properly on doors regardless of variations in door thicknesses. It should also be noted that the latch bolt assembly 14 is positively mounted with the latch bolt assembly holder 42 by means of the screw 64 and also the inside and outside operating cassettes 32 and 52 are held in proper alignment with the latch bolt assembly holder 28 by means of the projections 34, 36 and 54, 56 mating with the grooves 38 and 40 in the latch bolt assembly holder 42. This helps ensure proper alignment of the various components for insertion of the spindle 58.

Referring to Figures 2 and 22, the inside operating cassette 52 includes a cover 76 and outside operating cassette 32 includes a cover 78 both of which are provided with two spaced tabs members 80 extending inwardly therefrom into engagement with a mating slot 82 in the metal frame of the door 2 adjacent the opening therein. The engagement of the tabs 80 with the slots 82 help prevent the roses 28 and 46 and the inside and outside operating cassettes 32 and 52 from rotating relative to the door.

Referring now to Figures 2 and 5, the outside operating cassette 32 includes a housing 84 which has a central opening 86 into which the projection 30 of the outside lever 8 extends. The inside of the housing 84 includes a counterbore 88 concentric with the opening 86 and spaced wall portions 90 and 92 extending forwardly from the counterbore 88 in the direction of the extension of the latch bolt 14. The wall portions 90 and 92 taper outwardly and away from each other forming a V-shaped outer guideway 94. The inside surface of the housing 84 is also formed with a second set of opposed wall portions 96 and 98 spaced axially inwardly of said wall portions 90 and 92. The forward portions of the wall portions 96 and 98 are spaced apart a greater distance than the rearward portions forming upper and lower stop shoulders 100 (see Fig. 8). A rear wall portion 101 closes the end of an inner guideway 103 formed by the wall portions 96 and 98.

An actuating member 102 is mounted in the inner guideway 94 with a boss 105 thereof mounted in the opening 86 in the housing 84 and includes a generally square-shaped opening 104 into which extends the generally square-shaped projection 30 of the outside lever 8. The actuating member 102 includes a base portion 106 and a reduced elongated tail portion 110 which extends from the base portion 106 and is positioned within the V-shaped outer guideway 94. The forward end of the tail portion 110 is provided with a raised V-shaped cam surface 112 extending inwardly past the plane of the inner surface of the tail portion 110.

A spring plate 114 is mounted within the housing 84 of the outside operating cassette 32 in the inner guideway 103 in overlapping relationship with the actuating member 102. At its forward end the spring plate 114 includes two spaced fingers 116 and 118 each having a cam follower surface 120 thereon adapted to be engaged by the V-shaped cam surface 112 on the actuator member 102. The spring plate 114 is biased forwardly in the direction of extension of the latch bolt 14 into engagement with the cam surface 112 on the actuating member 102 by means of two lever springs 122 and 124 each of which is positioned in a suitable groove 126 provided in the housing 84 and extends from the rear wall portion 101 to the rearward end 128 of the spring plate 114.

The spring plate 114 has a cutout portion 130 in both its upper and lower side edges which form tab-engaging surfaces 132. The side edges ride between the wall portions 96 and 98 (see Fig. 8) with the forward end of the spring plate 114 being wider than the rearward end. The shoulders 134 formed between the wider forward portion and narrow rearward portion of the spring plate 114 form stop surfaces 135 for abutting the stop shoulders 100 formed in the housing 84.

A generally flat rack plate 136 is mounted within the housing 84 in the guideway 103 in overlapping relationship with the spring plate 114. The upper and lower edges of the rack plate 136 have outward extending tab portions 138 extending outward into the cutout portions 130 in the spring plate 114 in a position to be engaged by the tab-engaging surfaces 132 provided on the spring plate 114. The rack plate 136 also has a generally rectangular internal cutout 140, with the longer sides extending parallel to the axis of the latch bolt assembly 14. Gear teeth 142 are provided on the rack plate 136 adjacent one of the longer sides of the cutout 140 forming a rack which extends parallel to axis of the latch bolt assembly 14. Similar to the spring plate 114, the rack plate 136 is wider at its forward end between which and its narrower rearward end are formed stop shoulders 144 (see Fig. 7) adapted to abut the stop shoulders 100 formed in the housing 84. The forward end of the rack plate is provided with a notch 146 into which extends a lug portion 148 extending inwardly from the

forward end of the actuating member 102 when the rack plate is in its forward position shown in Figure 7 to prevent rotation of the actuating member 102. The rack plate 136 is biased into its forward position by a spring member 149 positioned in suitable groove 151 in the housing 84 and extending between the rear wall portion 101 of the housing 84 and the rearward end of the rack plate 136.

A pinion member 150 extends perpendicular to the axis of the latch bolt assembly 14 and is mounted within the outer operating cassette 32 and includes a set of gear teeth 152 which are in mating engagement with the gear teeth 142 on the rack plate 136. The pinion member 150 also includes a tubular extension portion 154 which extends through the spring plate 114, actuating member 102, and housing 84 into an opening 155 in the outside lever 8.

The pinion member 150 includes a head portion 156 which is contained within the inside of a boss 158 which extends inwardly on the cover member 76 which provides a bearing surface for the head portion 156. The head portion 156 of the pinion member 150 has a generally rectangular slot 160 therein of a mating cross-section with that of the spindle 58 which extends there-through. The tubular extension portion 154 includes opposed ribs 162 therein which are engagable by a drive member 164 connected to the lock cylinder 22 in the outside lever 8 to rotate the pinion member 150 between its unlocked and dead bolt positions.

In accordance with the above described arrangement, the actuating member 102 has pivotable movement about the axis of the spindle 58 and is operably attached to the outside lever 8. The spring plate 114 and rack plate 136 are mounted within the housing 84 for rectilinear motion in a direction parallel to the motion of the latch bolt 12 of the latch bolt assembly 14. To provide for a smooth action, the wall portions 96 and 98 of the housing 84 include wear pads 165 inserted therein which guide the spring plate 114 and rack plate 136 as shown in particular in Figures 7 and 8. The wear pads 165 may be fabricated from a suitable antifriction material such as Delrin which is a polyacetal.

The cover member 76 for the outside operating cassette 36 is provided with suitable cutout portions 166 through which the projections 34 and 36 extend to contain the operative parts of the operating housing as a unit. The cover member 76 is attached to the housing 84 by means of screws 168 extending through the cover member 76 into threaded bores 170 within the housing 84.

Referring to Figures 2 and 6 in particular, the inside operating assembly 44 includes the inside rose 46 and the inside lever 10 attached thereto in a similar manner as the outside operating assembly by a retaining ring 50. The inside operating cassette 52 includes basically the same elements and is constructed similar to that of the outside operating cassette 32 which has been

described above. Accordingly, the description of the various components of the inside operating cassette 52 will be relatively brief except for the differences between it and the outside operating cassette 32, which will be pointed out in more explicated detail below.

The inside operating cassette 52 includes a housing 172 having the projections 54 and 56 extending therefrom and in which is mounted for pivotal movement an inside actuating member 174 in a guideway 176 similar to that described above in connection with the outside actuating member 102. The inside actuating member 174 includes a central generally square-shaped opening 178 into which the square-shaped projection 48 of the inside lever 10 projects as well as a raised V-shaped cam portion 180. A spring plate 182 having cam surfaces 183 for engagement with the cam surface 180 on the actuating member 174 is mounted in a guideway 184 in the housing 172. As in the case of the outside operating mechanism, the spring plate 182 is spring-biased forwardly by spring members 186. The spring plate 182 also includes a cutout portion 188 in each of its side edges forming tab-engaging surfaces 190 and stop shoulders 192 adapted to engage stop shoulders 194 (see Fig. 11) in the housing 172.

A rack plate 196 having gear teeth 198 provided adjacent a rectangular cutout 200 forming a rack 202 is mounted in the guideway 184 overlapping the spring plate 182. The rack plate 196 is spring-biased forwardly by a spring member 204. The rack plate 196, also includes stop shoulders 205 adapted to engage the stop shoulder 194 in the housing 172 and outwardly extending tabs 206 extending into the cutout portions 188 in a position to be engaged by the tab-engaging portions 190 of the spring plate 182.

The guideway 184 also includes wear inserts 207 of the same type as described in connection above in connection with the outside housing 84. However, in contrast to the rack plate 136 of the outside operating assembly 27, the forward end of the rack plate 196 of the inside operating assembly 44 is foreshortened and does not include a notch so that when it is in its forward dead bolt position as shown in Figure 11 and the tabs 206 are in engagement with the tab-engaging surfaces 190 of the spring plate, the forward end does not come into engagement with the lug portion 209 on the actuating member 174. As a result, the actuating member 174 is free to pivot when the rack plate 196 is in its forward dead bolt position.

A pinion member 210 includes gear teeth 212 thereon in mating engagement with the teeth 198 on the rack plate 196. The pinion member 210 includes a tubular extension 213 having opposed ribs 214, 216 therein which extend through the inside operating cassette 52 into an opening 218 in the inside lever 10. The pinion member 210 further includes a head portion 220 which is contained within the boss 221 of the inside cover 78. The cover 78 is attached to the housing 172 by

means of screws 222 which are threadedly engaged with the housing 172. The head portion 220 of the pinion member 210 also includes a slot 224 through which one end of the spindle 58 extends.

Referring to Figures 2 and 15, the turn button 26 includes a knob 226 having a rod 228 extending inwardly therefrom. The end of the rod 228 includes two opposed radial extending ear portions 230 and 232 for engaging the opposed ribs 214 and 216 in the tubular extension 212 of the inside pinion member 210. A cam member 234 is mounted on the rod 228 having a cam slot 236 therein. A cam follower 238 in the form of a roll pin extends radially out from the rod into the cam slot 236. A spring 240 is provided between the cam member 234 and the knob 226 to bias the knob 226 outwardly.

The cam member 234 includes a bump 242 on its circumference which mates with an indentation 244 in the opening 218 in the inside lever 10 to prevent rotation of the cam member 234 with respect to the lever 10. The cam member 234 also includes inwardly projecting tongues 246 having shoulders 248 thereon. The turn button 26 is mounted in the opening 218 of the inside lever 10 with the body 250 of the cam member 234 engaging an outwardly facing shoulder 252 in the lever 10 and the shoulder 248 on the tongues 246 engaging an inwardly facing shoulder 254 in the lever 10. When mounted in the lever 10, the rod 228 extends into the pinion member 210 of the inside operating assembly.

The cam slot 236 extends partially around the circumference of the body 250 of the cam member and includes a generally straight portion 256 and an outwardly extending detent portion 258 which acts as a detent for the cam follower 238. When the knob 226 is rotated from its locked position to its unlocked position, the cam follower 238 will reach the outwardly extending detent portion 258. At this point, the knob 226 and rod 228 will move outwardly under the force of the spring 240, releasably holding the knob 226 in the unlocked position.

Referring to Figures 2 and 16-18, the latch bolt 12 of the latch bolt assembly 14 is shown movable between an extended position in Figure 16, a latching position in Figure 17 and an open position in Figure 18. The latch bolt assembly 14 includes a latch case 260 having two spaced latch plates 262 and 264 (Figure 2) extending rearwardly therefrom. The latch plates 262 and 264 are held mounted together by means of bushings 266. The latch bolt assembly 14 is mounted within the slot 43 in the latch bolt assembly holder 42 with the screw 64 which attaches the latch bolt assembly 14 to the latch bolt assembly holder 42 extending through the rearward one of the bushings 266.

A hub member 268 upon which two lever plates 270 are mounted for rotation therewith is mounted between the two latch plates 262 and 264 in suitable openings 272 therein. The hub member 268 has a generally rectangular bore 274

therethrough of a shape to receive the spindle 58. The bolt 12 is mounted within the latch case 260 and has an arm 276 extending rearwardly therefrom toward the lever plates 270. The arm 276 is pivotally attached at its forward end to the bolt 12 and at its rearward end has a pivot pin 278 extending through an elongated slot 280 in the lever plate 270. A guide 282 having opposed side walls in which the arm 276 is positioned is also pivotally attached to the rearward end of the bolt. A spring-biased dowel 284 is mounted in the bolt head and has its end face engaging one corner on the forward portion of the arm 276. This serves to bias the arm 276 in a direction such that the pivot pin 278 will engage the edge 286 of the latch plates 262 and 264 in a cutout portion 288. At the forward end of the cutout portion 288 there is a deeper cutout portion 290 forming a detent into which the pivot pin 278 is moved when the latch bolt 12 is moved into its extended dead bolt position.

The latch bolt 12 includes a bevelled forward portion 292 in a manner known in the art. The latch bolt 12 also includes a wear strip 294 of suitable wear resistance material (see Figure 25) of the type mentioned in connection with the wear pads 165 which extends about the exposed portions of the latch bolt 12 thereof including the bevelled forward portion 292 as well as the front and rear sides 296 and 298.

The wear strip 294 is mounted in a groove 300 in the latch bolt 12 and includes at the end of its front side a raised portion 302 which extends into the body of the latch bolt 12 and which is staked thereover. The spindle 58 extends between the two pinions 150 and 210 and through the hub member 268 of the latch bolt assembly 14.

In operation, when the latch bolt 12 is in its extended, dead bolt functioning position, the position of the various components of the outer operating cassette 32 are shown in Figures 7 and 8 and the position of the various components of the inside operating cassette 52 is shown in Figure 11. The spring plate 114 is urged radially forward in the housing 84 into engagement with the inner tip of the cam portion 112 of the actuating member 102. Likewise the spring 149 urges the rack plate 136 radially forward so that the tab portions 138 thereon engage the tab-engaging surfaces 132 on the spring plate 114. The lug portion 148 on the actuating member 102 is positioned in the notch 146 in the rack plate 136. This arrangement prevents the outside lever 8 from being turned since the actuating member 102 cannot be rotated. The components of the inside operating cassette 52 are in substantially the same position as the outside components with the spring plate 182 biased forwardly in the housing 172 by the springs 186 against the cam surface 180 on the actuating member 174. The rack plate 196 is spring-biased outwardly until its tabs 206 abut the tab-engaging portions 190 on the spring plate 182. In the case of the inside operating cassette however, the rack plate 196 does not engage the lug portion 208 on the

actuating member 174 and there is no blocking engagement thereof. Thus, the inside lever 10 is free to turn enabling the latch bolt 12 to be retracted. Upon rotating the inside lever 10, the actuating member 174 pivots about the axis of the spindle 58 and the cam surfaces 180 thereof engage the cam surfaces 183 on the end of the spring plate 182 causing the spring plate 182 to move rearwardly in a linear direction. Due to the engagement of the tab-engaging surfaces 190 on the spring plate 182 with the tabs 206 on the rack plate 196, the rack plate 196 will also be moved rearwardly in a linear direction. The rearward movement of the rack plate 196 causes the pinion member 210 to rotate thereby rotating the spindle 58 and the hub member 268 of the latch bolt assembly 14 causing complete retraction of the latch bolt 12. When the operator releases the lever 10, the spring plate 182 will move forward under the force of its associated springs 186 and the cam surfaces 183 will engage the cam surface 180 of the actuating member 174 moving the actuating member into its central position and thereby returning the lever 10 to its horizontal position and maintaining the lever 10 in that position. However, the spindle 58 and latch bolt 12 will not return to the dead bolt position, but rather to the latching position, wherein they are held there by means of the connection of the turn button 26 with the pinion member 210, as will be explained below. It is to be noted that since the pinions are directly linked by the spindle 58, rotation of one pinion will cause the rotation of the other with the result that the two rack plates always move together. However, the two spring plates are independently operated by their respective levers.

When the latch bolt 12 is in its latching or partially extended position, the components of the outer operating cassette 32 are positioned as shown in Figure 9. In this case, the spring plate 114 is forced by its associated springs 186 into its forward position wherein the cam surfaces 120 abut the cam surface 112 on the actuating member 102 and maintains the actuating member 102 in its central position in the guideway 94 and the outside lever 8 horizontal. The spring plate 182 and actuator member 174 in the inside cassette 52 are similarly positioned (see Fig. 13).

The rack plates 114 and 182 are held in the latching position by means of the inside pinion member 210 being held from rotation into its dead bolt position by means of the ribs 214, 216 in the extension 213 thereof engaging the ear portions 230, 232 on the rod of the turn button as shown in Figure 20 when the turn button 26 is in its unlocked position with the cam follower 258 positioned in the detent portion 258 of the cam slot 236. It is to be noted that the movement of the rack plates 114 and 182 from their open to their intermediate positions under the influence of their springs 149 and 204 serves to move the latch bolt from its retracted position to its latching position. This eliminates the need for a spring in the latch bolt assembly 14.

Due to the lost motion connection between the turn button 26 and pinion-member 210, the pinion member 210 is able to rotate from its latching position to its open position relative to the turn button thereby permitting the latch bolt 12 to be retracted when the door closes.

The turn button 26 and lock member 22 are connected to their respective pinion members 210 and 150 to drive them from their intermediate latching position into the dead bolt position merely by turning the turn button or rotating the lock with the key. This causes the pinions 210 and 150 to rotate the spindle 58 which in turn turns the hub member 268 of the latch bolt assembly 14 which drives the latch bolt 12 forward. If the key member is turned, the connection of the ear portions 230 and 232 of the turn button 26 with the ribs 214, 216 of the extension portion 213 of the inside pinion 210 causes the turn button 26 to move into its locked position (Fig. 19) wherein the cam follower 238 is moved out of the detent portion 258 in the cam surface 236 onto the flat portion 256 thereof. However, in the event of turning the knob 226 from its unlocked to locked position, there is sufficient lost motion between the driver 164 of the lock cylinder 22 and the internal ribs 162 in the pinion member 150 to permit the pinion member 150 to rotate into its dead bolt position without engaging the driver 164.

With reference to Figures 1, 2, 22 and 23, the lockset of the present invention includes a latch front 304 which is adaptable for both a bevelled door and a straight front door. In this connection, the latch front 304 has enlarged recesses 306 on its inside surface 308 to accommodate the tabs 310 of the casing of the lock assembly 14. The latch front 304 is held in the door by means of screw members 312 and includes an opening 314 therein through which the latch bolt 12 extends. The opening 314 of the front 304 is bevelled outwardly on both sides 3° with a flat in the middle.

While reference has been made above to a specific embodiment, it will be apparent to those skilled in the art that various modifications and alterations may be made thereto without departing from the scope of the present invention as defined by the appended claims.

Claims

1. A lockset for a door which comprises:
 - a latch bolt assembly (14) including a bolt (12) movable between a partially extended latching position, a fully extended dead bolt position, and a retracted position,
 - a spindle (58) extending through said latch assembly (14) in a direction transverse of the direction of movement of said bolt (12),
 - means (268, 270) connecting said spindle (58) to said bolt (12) for moving said bolt (12) between its positions upon rotation of said spindle (58), and
 - an operating assembly (27; 44) comprising a hand operator (8; 10) having a locking means (22;

26) therein, a first plate (114; 182) mounted for linear movement in a direction transverse to the axis of said spindle (58), an actuating member (102; 174) connected to said hand operator (8; 10) for moving said first plate (114; 182), and rotatable drive means (150; 210) attached to said spindle (58) characterised in that said operating assembly (27; 44) further comprises a second plate (136; 196) having linear movement transverse to the axis of said spindle (58) and adapted to be moved by said first plate (114, 182), so that said actuating member (102; 174) can be locked in a dead bolt position to prevent movement of said latch bolt (12) from said fully extended position to said retracted position and that said rotatable drive means (150; 210) is adapted to be rotated by said second plate (136; 196).

2. A lockset according to Claim 1 characterised in that the second plate (136; 196) has gear teeth (142; 198) thereon and said rotatable drive means (150; 210) includes a pinion (152; 212) in engagement with said gear teeth (142; 198).

3. A lockset according to Claim 1 or Claim 2 characterised in that the locking means (22; 26) rotates said rotatable drive means (150; 210) to move the bolt (12) to its fully extended position.

4. A lockset according to any one of the preceding Claims characterised in that the first plate (114; 182) includes a cam surface (120; 183) and the actuating member (102; 174) is pivotably mounted and includes a cam surface (112; 180) for engaging the cam surface (120; 183) on the first plate (114; 182) to move said first plate linearly when the actuating member (102; 174) is pivoted.

5. A lockset according to any one of the preceding Claims characterised in that the drive means (150; 210) is rotatable in one direction to move the bolt (12) from its retracted position to its partially extended position and its fully extended position, and further in that means (214, 216, 230, 232) is provided for preventing said drive means (150; 210) from rotating to move the bolt (12) from its partially extended position to its fully extended position when the locking means (22; 26) is unlocked, but permitting said drive means (150; 210) to be rotated in the other direction to move the bolt (12) from its partially extending position to its retracted position.

6. A lockset according to any one of the preceding Claims wherein two operating assemblies (27, 44) are provided, one (27) for mounting on the outside and the other (44) on the inside of a door (2).

7. A lockset according to Claim 6 when tied to Claim 5 characterised in that the locking means (26) of the inside operating assembly (44) is a turn button (26) mounted in the hand operator (10) for movement between an unlocked position and a locked position, and the means (214, 216, 230, 232) for preventing rotation of the drive means (210) includes means (214, 216, 230, 232) interconnecting said turn button (26) and said drive means (210).

8. A lockset according to Claim 7 characterised

Due to the lost motion connection between the turn button 26 and pinion-member 210, the pinion member 210 is able to rotate from its latching position to its open position relative to the turn button thereby permitting the latch bolt 12 to be retracted when the door closes.

The turn button 26 and lock member 22 are connected to their respective pinion members 210 and 150 to drive them from their intermediate latching position into the dead bolt position merely by turning the turn button or rotating the lock with the key. This causes the pinions 210 and 150 to rotate the spindle 58 which in turn turns the hub member 268 of the latch bolt assembly 14 which drives the latch bolt 12 forward. If the key member is turned, the connection of the ear portions 230 and 232 of the turn button 26 with the ribs 214, 216 of the extension portion 213 of the inside pinion 210 causes the turn button 26 to move into its locked position (Fig. 19) wherein the cam follower 238 is moved out of the detent portion 258 in the cam surface 236 onto the flat portion 256 thereof. However, in the event of turning the knob 226 from its unlocked to locked position, there is sufficient lost motion between the driver 164 of the lock cylinder 22 and the internal ribs 162 in the pinion member 150 to permit the pinion member 150 to rotate into its dead bolt position without engaging the driver 164.

With reference to Figures 1, 2, 22 and 23, the lockset of the present invention includes a latch front 304 which is adaptable for both a bevelled door and a straight front door. In this connection, the latch front 304 has enlarged recesses 306 on its inside surface 308 to accommodate the tabs 310 of the casing of the lock assembly 14. The latch front 304 is held in the door by means of screw members 312 and includes an opening 314 therein through which the latch bolt 12 extends. The opening 314 of the front 304 is bevelled outwardly on both sides 3° with a flat in the middle.

While reference has been made above to a specific embodiment, it will be apparent to those skilled in the art that various modifications and alterations may be made thereto without departing from the scope of the present invention as defined by the appended claims.

Claims

1. A lockset for a door which comprises:
 - a latch bolt assembly (14) including a bolt (12) movable between a partially extended latching position, a fully extended dead bolt position, and a retracted position,
 - a spindle (58) extending through said latch assembly (14) in a direction transverse of the direction of movement of said bolt (12),
 - means (268, 270) connecting said spindle (58) to said bolt (12) for moving said bolt (12) between its positions upon rotation of said spindle (58), and
 - an operating assembly (27; 44) comprising a hand operator (8; 10) having a locking means (22;

26) therein, a first plate (114; 182) mounted for linear movement in a direction transverse to the axis of said spindle (58), an actuating member (102; 174) connected to said hand operator (8; 10) for moving said first plate (114; 182), and rotatable drive means (150; 210) attached to said spindle (58) characterised in that said operating assembly (27; 44) further comprises a second plate (136; 196) having linear movement transverse to the axis of said spindle (58) and adapted to be moved by said first plate (114, 182), so that said actuating member (102; 174) can be locked in a dead bolt position to prevent movement of said latch bolt (12) from said fully extended position to said retracted position and that said rotatable drive means (150; 210) is adapted to be rotated by said second plate (136; 196).

2. A lockset according to Claim 1 characterised in that the second plate (136; 196) has gear teeth (142; 198) thereon and said rotatable drive means (150; 210) includes a pinion (152; 212) in engagement with said gear teeth (142; 198).

3. A lockset according to Claim 1 or Claim 2 characterised in that the locking means (22; 26) rotates said rotatable drive means (150; 210) to move the bolt (12) to its fully extended position.

4. A lockset according to any one of the preceding Claims characterised in that the first plate (114; 182) includes a cam surface (120; 183) and the actuating member (102; 174) is pivotably mounted and includes a cam surface (112; 180) for engaging the cam surface (120; 183) on the first plate (114; 182) to move said first plate linearly when the actuating member (102; 174) is pivoted.

5. A lockset according to any one of the preceding Claims characterised in that the drive means (150, 210) is rotatable in one direction to move the bolt (12) from its retracted position to its partially extended position and its fully extended position, and further in that means (214, 216, 230, 232) is provided for preventing said drive means (150; 210) from rotating to move the bolt (12) from its partially extended position to its fully extended position when the locking means (22; 26) is unlocked, but permitting said drive means (150, 210) to be rotated in the other direction to move the bolt (12) from its partially extending position to its retracted position.

6. A lockset according to any one of the preceding Claims wherein two operating assemblies (27, 44) are provided, one (27) for mounting on the outside and the other (44) on the inside of a door (2).

7. A lockset according to Claim 6 when tied to Claim 5 characterised in that the locking means (26) of the inside operating assembly (44) is a turn button (26) mounted in the hand operator (10) for movement between an unlocked position and a locked position, and the means (214, 216, 230, 232) for preventing rotation of the drive means (210) includes means (214, 216, 230, 232) interconnecting said turn button (26) and said drive means (210).

8. A lockset according to Claim 7 characterised

in that the locking means (22) of the outside operating assembly (27) is a cylinder lock (22) which, when locked, causes the turn button (26) of the inside operating assembly (44) to move to its locked position and thus to cause the bolt (12) to be moved to its fully extended position.

9. A lockset according to Claim 6 or Claim 7 characterised in that means (146, 148) is provided whereby pivoting of the outside actuating member (8) is prevented when the bolt (12) is in its fully extended position.

10. A lockset according to Claim 9 characterised in that the means (146, 148) preventing pivoting of the outside actuating member (8) comprises a lug (148) extending inwardly from the outside actuating member (102) and the outside second plate (136) has a notch (146) in its end portion engagable with said lug (148) when said second plate (136) is in an advanced position corresponding to the fully extended position of the bolt (12).

11. A lockset according to any of Claims 1 to 10 characterised in that the latch bolt assembly (14) is mounted within a latch bolt holder (42), the outside operating assembly (27) has at least one inwardly extending projection (34; 36) extending therefrom, the inside operating assembly (44) has at least one inwardly extending projection (54; 56) extending therefrom, said latch bolt holder (42) has at least one groove (38; 40) therein, and the projections (34; 36, 54; 56) of said outside and inside operating assemblies (27, 44) are received within said groove (38; 40).

12. A lockset according to any of Claims 7 to 11 characterised in that said hand operator (10) has an opening (218) therein including an inwardly facing surface (254) and an outwardly facing surface (252), and said turn button (26) has associated therewith a body portion (250) engaging said outward facing surface (254) and tongue members (246) having shoulders (248) engaging said inwardly facing surface (254), movement of said turn button (26) from an unlocked to a locked position thus causing the latch bolt (12) to be moved into its fully extended position.

13. A lockset according to Claim 12 characterised in that the turn button (26) comprises an actuator member (228) having a cam follower (234) therein, said body portion (250) having a cam slot (236) into which said cam follower (234) extends and which comprises a detent portion (258) to releasably hold the turn button (26) in its unlocked position.

14. A lockset according to any one on the preceding Claims characterised in that the latch bolt (12) has a continuous groove (300) which extends on the inside surface, front surface and outside surface thereof and in which a wear strip (294) is positioned.

Patentansprüche

1. Schloß für eine Tür, welches eine Verriegelungsanordnung (14) mit einem Bolzen (12) umfaßt, der zwischen einer teilweise ausge-

fahrenen Verriegelungslage, einer vollständig ausgefahrenen Totlage und einer zurückgezogenen Lage bewegbar ist, mit einer Spindel (58), die sich durch die Verriegelungsanordnung (14) in einer Richtung erstreckt, die quer zur Bewegungsrichtung des Bolzens (12) verläuft, mit einer Einrichtung (268, 270), welche die Spindel (58) mit dem Bolzen (12) verbindet, um letzteren bei Drehen der Spindel (58) zwischen seinen Lagen zu bewegen, und mit einer Betätigungsanordnung (27; 44), die einen eine Sperreinrichtung (8; 10) aufweisenden Betätiger (22; 26), eine erste Platte (114; 182), die in einer Richtung quer zur Achse der Spindel (58) linear bewegbar ist, ein Betätigungsglied (102; 174), welches mit dem Betätiger (8; 10) verbunden ist, um diese erste Platte (114; 182) zu bewegen, und eine drehbare Antriebseinrichtung (150; 210) umfaßt, welche an der Spindel (58) befestigt ist, dadurch gekennzeichnet, daß die Betätigungsanordnung (27; 44) eine zweite Platte (136; 196) umfaßt, die quer zur Achse der Spindel (58) linear und von der ersten Platte (114, 182) bewegbar ist, so daß das Betätigungsglied (102; 174) in der Bolzentotlage gesperrt werden kann, um ein Bewegen des Verriegelungsbolzens (12) aus seiner vollständig ausgefahrenen Lage in die zurückgezogene Lage zu verhindern, und daß die drehbare Antriebseinrichtung (150; 210) von der zweiten Platte (136; 196) drehbar ist.

2. Schloß nach Anspruch 1, dadurch gekennzeichnet, daß die zweite Platte (136; 196) Zähne (142; 198) aufweist, und daß die drehbare Antriebseinrichtung (150; 210) ein Ritzel (152; 212) einschließt, das mit den Zähnen (142; 198) kämmt.

3. Schloß nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß die drehbare Antriebseinrichtung (150; 210) von der Sperreinrichtung (22; 26) drehbar ist, um den Bolzen (12) in seine vollständig ausgefahrene Lage zu bewegen.

4. Schloß nach einem der vorhergehenden Ansprüche, dadurch gekennzeichnet, daß die erste Platte (114; 182) eine Nockenfläche (120; 183) aufweist und daß das Betätigungsglied (102; 174) schwenkbar gelagert ist und eine Nockenfläche (112; 180) zwecks Eingriffes mit der Nockenfläche (120; 183) der ersten Platte (114; 182) umfaßt, um beim Schwenken des Betätigungsgliedes (102; 174) die erste Platte (114; 182) linear zu bewegen.

5. Schloß nach einem der vorhergehenden Ansprüche, dadurch gekennzeichnet, daß die Antriebseinrichtung (150; 210) in einer Richtung drehbar ist, um den Bolzen (12) aus seiner zurückgezogenen Lage in seine teilweise ausgefahrene und in seine vollständig ausgefahrene Lage zu bewegen, und daß eine Einrichtung (214, 216, 230, 232) vorgesehen ist, welche ein Drehen der Antriebseinrichtung (150; 210), um den Bolzen (12) aus seiner teilweise ausgefahrenen Lage in seine vollständig ausgefahrene Lage zu bewegen, verhindert, wenn die Sperreinrichtung (22; 26) entriegelt ist, welche indessen gestattet, daß die Antriebseinrichtung (150; 210) in der anderen Richtung drehbar ist, um den Bolzen (12) aus

seiner teilweise ausgefahrenen Lage in seine zurückgezogene Lage zu bewegen.

6. Schloß nach einem der vorhergehenden Ansprüche, dadurch gekennzeichnet, daß zwei Betätigungsanordnungen (25, 44) vorgesehen sind, von denen eine Anordnung (27) an der Außenseite und die andere Anordnung (44) an der Innenseite einer Tür (22) angeordnet sind.

7. Schloß nach Anspruch 5 und 6, dadurch gekennzeichnet, daß die Sperreinrichtung (26) der inneren Betätigungsanordnung (44) ein Drehknopf (26) ist, welcher zwecks Bewegung zwischen einer Verriegelungslage und einer Entriegelungslage in dem Betätiger (10) angeordnet ist, und daß die Einrichtung (214, 216, 230, 232) zum Verhindern eines Drehens der Antriebseinrichtung (210) eine Einrichtung (214, 216, 230, 232) einschließt, welche den Drehknopf (26) mit der Antriebseinrichtung (210) verbindet.

8. Schloß nach Anspruch 7, dadurch gekennzeichnet, daß die Sperreinrichtung (22) der äußeren Betätigungsanordnung (27) ein Zylinderschloß (22) ist, welches im verriegelten Zustand verursacht, daß sich der Drehknopf (26) der inneren Betätigungsanordnung (44) in seine Sperrlage bewegt, so daß der Bolzen (12) in seine vollständig ausgefahrne Lage bewegt wird.

9. Schloß nach Anspruch 6 oder 7, dadurch gekennzeichnet, daß eine Einrichtung (146, 148) vorgesehen ist, so daß ein Schwenken des äußeren Betätigungsgliedes (8) verhindert ist, wenn sich der Bolzen (12) in seiner vollständig ausgefahrenen Lage befindet.

10. Schloß nach Anspruch 9, dadurch gekennzeichnet, daß die ein Schwenken des äußeren Betätigungsgliedes (8) verhindernde Einrichtung (146, 148) einen Ansatz (148) aufweist, der sich von dem äußeren Betätigungsglied (102) einwärts erstreckt, und daß die zweite Platte (136) eine Ausnehmung (146) in ihrem Endabschnitt aufweist, welche mit dem Ansatz (148) in Eingriff ist, wenn sich die zweite Platte (136) entsprechend der vollständig ausgefahrenen Lage des Bolzens (12) in einer vorgeschobenen Lage befindet.

11. Schloß nach einem der Ansprüche 1 bis 10, dadurch gekennzeichnet, daß die Verriegelungsanordnung (14) in einem Verriegelungsbolzenhalter (42) angeordnet ist, daß die äußere Betätigungsanordnung (27) wenigstens einen sich einwärts erstreckenden Vorsprung (34; 36) aufweist, daß die innere Betätigungsanordnung (44) wenigstens einen sich einwärts erstreckenden Vorsprung (54; 56) aufweist, daß der Verriegelungsbolzenhalter (42) wenigstens eine Ausnehmung (38; 40) aufweist, und daß die Vorsprünge (34; 36, 54; 56) der äußeren und inneren Betätigungsanordnungen (27, 44) innerhalb dieser Ausnehmung (38; 40) aufgenommen sind.

12. Schloß nach einem der Ansprüche 7 bis 11, dadurch gekennzeichnet, daß der Betätiger (10) eine Öffnung, (218) mit einer einwärts weisenden Fläche (254) und einer auswärts weisenden Fläche (252) aufweist, und daß der Drehknopf (26) einem Körperabschnitt (250) zugeordnet ist, welcher mit der auswärts weisenden Fläche (252)

in Eingriff steht, und daß Zungenteile (246) mit Schultern (248) mit der einwärts weisenden Fläche (254) in Eingriff sind, so daß durch ein Bewegen des Drehknopfes (26) aus einer entriegelten Lage in eine Sperrlage der Verriegelungsbolzen (12) in seine vollständig ausgefahrne Lage bewegbar ist.

13. Schloß nach Anspruch 12, dadurch gekennzeichnet, daß der Drehknopf (26) ein Betätigungsglied (228) mit einem Nockenfolgeglied (234) aufweist, daß der Körperabschnitt (250) einen Nockenschlitz (236) aufweist, in welchen sich das Nockenfolgeglied (234) erstreckt, und daß ein Sperrabschnitt (258) vorgesehen ist, welcher den Drehknopf (26) lösbar in seiner entriegelten Lage hält.

14. Schloß nach einem der vorhergehenden Ansprüche, dadurch gekennzeichnet, daß der Verriegelungsbolzen (12) eine sich an der Innenfläche, Vorderfläche und Außenfläche erstreckende Ausnehmung (300) aufweist, in welcher ein Gleitstück (294) angeordnet ist.

Revendications

1. Ensemble serrure complète pour porte qui comprend:

un ensemble de pêne demi-tour (14) dont font partie un pêne (12) qui peut se déplacer entre une position de pêne demi-tour ou partiellement déplacée, une position de pêne dormant ou entièrement déployée et une position escamotée,

une broche (58) qui traverse cet ensemble de pêne demitour (14) dans une direction transversale à la direction du déplacement de ce pêne (14),

des moyens (268, 270) qui relient cette broche (58) à ce pêne (12) pour déplacer ce pêne (12) entre ses positions en réponse à la rotation de cette broche (58), et

un ensemble de commande (27; 44) dont font partie un actionneur manuel (8; 10) qui possède intérieurement des moyens de condamnation (22; 26), une première plaque (114; 182) montée pour décrire un déplacement rectiligne dans une direction transversale à l'axe de cette broche (58), un élément d'actionnement (102; 174) relié à cet actionneur (8; 10) pour mouvoir cette première plaque (114; 182), et des moyens d'entraînement rotatifs (150; 210) fixés à cette broche (58), caractérisé en ce que cet ensemble de commande (27; 44) comprend, en outre, une deuxième plaque (136; 196) pouvant décrire un déplacement rectiligne transversal à l'axe de cette broche (58) et adaptée pour être mue par cette première plaque (114; 182), de sorte que cet élément d'actionnement (102; 174) peut être bloqué dans une position de pêne dormant, pour empêcher ce pêne demi-tour (12) de passer de cette position entièrement déployée à cette position escamotée et en ce que ces moyens d'entraînement rotatifs (150; 210) sont adaptés pour être entraînés en rotation par cette deuxième plaque (136; 196).

2. Ensemble serrure complète selon la revendication 1, caractérisé en ce que la deuxième plaque

(136; 196) porte des dents d'engrenage (142; 198) et ces moyens d'entraînement rotatifs (150; 210) comprennent un pignon (152; 212) qui est en prise avec ces dents d'engrenages (142; 198).

3. Ensemble serrure complète selon la revendication 1 ou la revendication 2, caractérisé en ce que les moyens de verrouillage (22; 26) font tourner ces moyens d'entraînement rotatifs (150; 210) pour placer le pêne demi-tour (12) à sa position intérieurement déployée.

4. Ensemble serrure complète selon l'une quelconque des revendications précédentes, caractérisé en ce que la première plaque (114; 182) comprend une surface de came (120; 183) et l'élément d'actionnement (102; 174) est monté pivotant et comprend une surface de came (112; 180) destinée à attaquer la surface de came (120; 183) prévue sur la première plaque (114; 182) pour déplacer cette dernière suivant une course rectiligne lorsque l'élément d'actionnement (102; 174) tourne.

5. Ensemble serrure complète selon l'une quelconque des revendications précédentes, caractérisé en ce qu'on peut faire tourner les moyens d'entraînement (150; 210) dans un sens pour faire passer le pêne demi-tour (12) de sa position escamotée à sa position partiellement déployée et à sa position entièrement déployée et, en outre, en ce que des moyens (214; 216; 230; 232) sont prévus pour empêcher ces moyens d'entraînement (150; 210) de tourner pour faire passer le pêne demi-tour (12) de sa position partiellement déployée à sa position entièrement déployée lorsque les moyens de verrouillage (22; 26) sont déverrouillés, mais pour permettre de faire tourner ces moyens d'entraînement (150; 210) dans le sens opposé pour faire passer le pêne demi-tour (12) de sa position partiellement déployée à sa position escamotée.

6. Ensemble serrure complète selon l'une quelconque des revendications précédentes, dans lequel sont prévus deux ensembles de commande (27, 44), l'un (27) destiné à être monté sur l'extérieur d'une porte (2) et l'autre (44) sur l'intérieur de cette porte.

7. Ensemble serrure complète selon la revendication 6, rattachée à la revendication 5, caractérisé en ce que les moyens de verrouillage (26) de l'ensemble de commande intérieur (44) sont un bouton tournant (26) monté dans l'actionneur manuel (10) pour se déplacer entre une position déverrouillée et une position verrouillée, et les moyens (214, 216, 230, 262) servant à empêcher la rotation des moyens d'entraînement (210) comprennent des moyens (214, 216, 230, 232) qui relient ce bouton tournant (26) et ces moyens d'entraînement (210).

8. Ensemble serrure selon la revendication 7, caractérisé en ce que les moyens de verrouillage (22) de l'ensemble de commande extérieur (27) sont un barillet de serrure (22) qui, lorsqu'il est verrouillé, fait passer le bouton tournant (26) de l'ensemble de commande intérieur (44) à sa position verrouillée et fait ainsi passer le pêne

demi-tour (12) à sa position entièrement déployée.

9. Ensemble serrure selon la revendication 6 ou la revendication 7, caractérisé en ce qu'il est prévu des moyens (146, 148) sous l'action desquels le pivotement de l'élément d'actionnement extérieur (8) est interdit lorsque le pêne (12) se trouve dans sa position entièrement déployée.

10. Ensemble serrure complète selon la revendication 9, caractérisé en ce que les moyens (146, 148) qui empêchent le pivotement de l'élément d'actionnement extérieur (8) comprennent une patte (148) qui fait saillie vers l'intérieur sur l'élément d'actionnement extérieur (102) et la deuxième plaque extérieure (136) présente dans sa portion d'extrémité une encoche (146) qui peut être mise en prise avec cette patte (148) lorsque cette deuxième plaque (136) se trouve dans une position avancée qui correspond à la position entièrement déployée du pêne demi-tour (12).

11. Ensemble serrure complète selon l'une quelconque des revendications 1 à 10, caractérisé en ce que l'ensemble de pêne demi-tour (14) est monté dans un support de pêne demi-tour (42), l'ensemble de commande extérieur (27) porte au moins une protubérance (34, 36) s'étendant vers l'intérieur qui fait saillie sur cet ensemble, l'ensemble de commande intérieur (44) porte au moins une protubérance (54; 56) dirigée vers l'intérieur, qui fait saillie sur cet ensemble, ce support de pêne demi-tour (42) présente au moins une rainure (38; 40) et les protubérances (34; 36, 54; 56) de ces ensembles de commande extérieur et intérieur (27, 44) se logent dans cette rainure (38; 40).

12. Ensemble serrure complète selon l'une quelconque des revendications 7 à 11, caractérisé en ce que cet actionneur manuel (10) présente intérieurement une ouverture (118) qui comprend une surface (254) regardant vers l'intérieur et une surface (252) regardant vers l'extérieur, et, à ce bouton tournant (26) est associée une portion corps (250) qui attaque cette surface (254) regardant vers l'extérieur et des éléments languettes (246) possédant des épaulements (148) qui attaquent cette surface (154) regardant vers l'intérieur, le déplacement de ce bouton tournant (26), pour passer d'une position déverrouillée à une position verrouillée, faisant ainsi passer le pêne demi-tour (12) à sa position entièrement déployée.

13. Ensemble serrure complète selon la revendication 12, caractérisé en ce que le bouton tournant (26) comprend un élément actionneur (228) contenant une contre-came (234), cette portion corps (250) ayant une fente de came (236) dans laquelle pénètre cette contre-came (234) et qui comprend une portion d'encliquetage (258) destinée à maintenir le bouton tournant (26) dans sa position déverrouillée par une liaison séparable.

14. Ensemble serrure complète selon l'une quelconque des revendications précédentes,

caractérisé en ce que le pêne demi-tour (12) présente une rainure continue (300) qui s'étend sur sa surface interne, sa surface avant et sa

surface externe, et dans laquelle est logée une bande d'usure (294).
