

METHODS OF TREATMENT FOR CHOLESTATIC AND FIBROTIC DISEASES

TECHNICAL FIELD

5 The present invention relates to the field of medicine, in particular to the treatment of cholestatic or fibrotic diseases.

BACKGROUND

10 Abnormal and exaggerated deposition of extracellular matrix is the hallmark of all fibrotic diseases, including liver, pulmonary, kidney or cardiac fibrosis. The spectrum of affected organs, the progressive nature of the fibrotic process, the large number of affected persons, and the absence of effective treatment pose an enormous challenge when treating fibrotic diseases.

15 In an attempt to propose new therapeutic strategies for the treatment of fibrotic diseases, the inventors found that 2-[(5-nitro-1,3-thiazol-2-yl)carbamoyl]phenyl]ethanoate (Nitazoxanide - NTZ), a synthetic antiprotozoal agent or its deuterated derivatives or its active metabolite 2-hydroxy-N-(5-nitro-2-thiazolyl)benzamide (Tizoxanide, known as TZ) in combination with statins show synergistic antifibrotic activities. Moreover, the evaluation of NTZ combined to a statin in a liver injury model revealed its capacity to reduce circulating
20 bile acid concentration, thus reflecting the synergistic potential of this combination to treat both cholestatic (such as PBC and PSC) and fibrotic diseases.

 NTZ, first described in 1975 (Rossignol and Cavier, 1975), was shown to be highly effective against anaerobic protozoa, helminths, and a wide spectrum of microbes including both anaerobic and aerobic bacteria (Rossignol and Maisonneuve, 1984; Dubreuil, Houcke
25 *et al.*, 1996; Megraud, Occhialini *et al.*, 1998; Fox and Saravolatz, 2005; Pankuch and Appelbaum, 2006; Finegold, Molitoris *et al.*, 2009). It was first studied in humans for the treatment of intestinal cestodes (Rossignol and Maisonneuve, 1984) and it is now licensed in the United States (Alinia®, Romark laboratories) for the treatment of diarrhea caused by the protozoan parasites *Cryptosporidium parvum* and *Giardia intestinalis*. NTZ has also been
30 widely commercialized in Latin America and in India where it is indicated for treating a broad spectrum of intestinal parasitic infections (Hemphill, Mueller *et al.*, 2006). The proposed mechanism of action by which NTZ exerts its antiparasitic activity is through the inhibition of pyruvate:ferredoxin oxidoreductase (PFOR) enzyme-dependent electron transfer reactions that are essential for anaerobic metabolism (Hoffman, Sisson *et al.*, 2007). NTZ also
35 exhibited activity against *Mycobacterium tuberculosis*, which does not possess a homolog of PFOR, thus suggesting an alternative mechanism of action. Indeed, the authors showed that

NTZ can also act as an uncoupler disrupting membrane potential and intra-organism pH homeostasis.(de Carvalho, Darby *et al.*, 2011).

The pharmacological effects of NTZ are not restricted to its antiparasitic or antibacterial activities and in recent years, several studies revealed that NTZ can also confer antiviral activity (Di Santo and Ehrisman, 2014; Rossignol, 2014). NTZ interferes with the viral replication by diverse ways including a blockade in the maturation of hemagglutinin (influenza) or VP7 (rotavirus) proteins, or the activation of the protein PKR involved in the innate immune response (for a review, see (Rossignol, 2014)). NTZ was also shown to have broad anticancer properties by interfering with crucial metabolic and prodeath signaling pathways (Di Santo and Ehrisman, 2014).

Statins (3-hydroxy-3-methylglutaryl-coenzyme A reductase inhibitors) are commonly prescribed as medications for the treatment of hypercholesterolemia and for the prevention of cardiovascular disease.

There are currently 7 unique prescribed statins that include pravastatin, simvastatin, and lovastatin (which are naturally-derived from fungal fermentation) and a second group of chemically synthesized statins composed of fluvastatin, atorvastatin, rosuvastatin and pitavastatin. Although all statins contain a dihydroxy-heptanoic acid HMG-CoA like moiety, which competes for binding to HMG-CoA reductase, each statin is unique and exhibits significant differences in chemical structure, potency (ex. IC₅₀ for HMG-CoA reductase inhibition), tissue penetration and retention, half-life, metabolism and elimination, drug-drug interactions, and safety. The mechanisms involved in the beneficial effects of statins on the prevention of cardiovascular disease have been largely attributed to the ability of these agents to inhibit cholesterol biosynthesis. Owing to the fact that 60-70% of serum cholesterol is derived from hepatic biosynthesis and that HMG-CoA reductase is the crucial, rate-limiting enzyme in the cholesterol biosynthetic pathway, it is not surprising that inhibition of this enzyme results in a dramatic reduction in circulating LDL-Cholesterol. Moreover, reduction of LDL-cholesterol leads to upregulation of hepatic LDL receptors and increase of LDL clearance. Both clinical and experimental data suggest that the sum of benefits from statin therapy may extend well beyond their favorable effects on serum cholesterol levels. These cholesterol-independent effects, described as pleiotropic effects of statins, are related to the reduced formation of isoprenoids. Indeed, inhibition of HMG-CoA reductase results not only in deprivation of intracellular mevalonate but also several downstream isoprenoid derivatives including farnesyl pyrophosphate (FPP) and geranylgeranylpyrophosphate(GGPP). Both FPP and GGPP are required for posttranslational prenylation of a number of proteins (approximately 2% of total cellular proteins, (Wang, Liu *et al.*, 2008)). Protein isoprenylation enables proper subcellular localization and trafficking of intracellular molecules. For example,

non-isoprenylated GTPases remain cytosolic whereas isoprenylated GTPases harbour a FPP or GGPP lipid attachment that permits insertion and anchorage into the cell membrane, and subsequently participate in signal transduction. Therefore, inhibiting isoprenylation results in the inactivation of the small GTPases (ex Rho, Ras, Rac and Cdc42) which are essential in many cellular events (intracellular signal transduction, cellular proliferation, inflammation, motility, (for a review see (McFarlane, Muniyappa *et al.*, 2002; Zhou and Liao, 2009; Yeganeh, Wiechec *et al.*, 2014; Kavalipati, Shah *et al.*, 2015)). Since it has been demonstrated that the Rho GTPase and its target protein Rock are involved in the activation/differentiation of fibroblasts into myofibroblasts (Ji, Tang *et al.*, 2014), a key event in the fibrotic process, several studies were conducted with statins to evaluate their antifibrotic properties in different pathological models. Simvastatin was shown to reduce the expression of fibrotic markers in both human and rat HSC and to confer antifibrotic properties in various animal models of fibrosis (Rombouts, Kisanga *et al.*, 2003; Watts, Sampson *et al.*, 2005; Wang, Zhao *et al.*, 2013; Marrone, Maeso-Diaz *et al.*, 2015). As well, Pitavastatin (Miyaki, Nojiri *et al.*, 2011) and Fluvastatin (Chong, Hsu *et al.*, 2015) were able to reduce fibrosis in the CDAA diet-induced NAFLD/NASH model. These beneficial effects of statins are not restricted to liver fibrosis. Indeed, it was demonstrated that Atorvastatin was significantly potent against bleomycin-induced lung fibrosis (Zhu, Ma *et al.*, 2013) while Simvastatin was shown to inhibit expression of fibrotic markers in fibroblasts derived from human fibrotic lung. (Watts, Sampson *et al.*, 2005).

In this invention, using a phenotypic screening assay to identify potential antifibrotic agents, it was discovered that NTZ or its deuterated derivatives or its active metabolite TZ, in combination with a statin, interferes, in an additive or synergistic manner, with the activation of myofibroblasts. This effect was totally unexpected in view of the properties previously reported for these molecules. Combination of NTZ or its deuterated derivatives or TZ with a specific statin appears as a potent therapeutic strategy for diverse types of fibrotic diseases. Moreover, the evaluation of NTZ or derivatives thereof in combination with a specific statin revealed an unexpected synergistic capacity to reduce circulating bile acid concentration, thus reflecting its potential to treat both cholestatic diseases (such as PBC and PSC) and fibrotic diseases.

SUMMARY OF INVENTION

The present invention relates to a synergistic combination comprising (i) [2-[(5-nitro-1,3-thiazol-2-yl)carbamoyl]phenyl]ethanoate (NTZ), a deuterated derivative of NTZ (NTZ-D), 2-hydroxy-N-(5-nitro-2-thiazolyl)benzamide (TZ), or Tizoxanide glucuronide (TZG) and (ii) at

least one statin. This combination is useful in a method for the treatment of a cholestatic or fibrotic disease.

Therefore, the present invention relates to a synergistic combination of

5 (i) NTZ, NTZ-D, TZ or TZG, or a pharmaceutically acceptable salt of NTZ, NTZ-D, TZ or TZG;

(ii) a statin.

The combination of the invention may be in the form of a pharmaceutical composition

10 or of a kit-of-parts.

Furthermore, the components of the synergistic combination of the invention may be administered simultaneously, sequentially and separately.

15 In a particular embodiment, component (i) of the synergistic combination is NTZ or a pharmaceutically acceptable salt thereof.

In a particular embodiment of the invention, said at least one statin is selected in the group consisting of mevastatin, cerivastatin, pitavastatin, fluvastatin, simvastatin,

20 atorvastatin, lovastatin, rosuvastatin, and pravastatin. In another particular embodiment, the statin is selected in the group consisting of pitavastatin, fluvastatin, simvastatin and atorvastatin. In another particular embodiment, the statin is selected in the group consisting of pitavastatin, fluvastatin and simvastatin.

25

Furthermore, the synergistic combination of the invention may further comprise at least one therapeutically active agent with known antifibrotic activity selected from

30 pirfenidone or receptor tyrosine kinase inhibitors (RTKIs) such as Nintedanib, Sorafenib and other RTKIs, or angiotensin II (AT1) receptor blockers, or CTGF inhibitor, or any antifibrotic compound susceptible to interfere with the TGF β and BMP-activated pathways including activators of the latent TGF β complex such as MMP2, MMP9, THBS1 or cell-surface integrins, TGF β receptors type I (TGFBRI) or type II (TGFBRII) and their ligands such as TGF β , Activin, inhibin, Nodal, anti-Müllerian hormone, GDFs or BMPs, auxiliary co-receptors

(also known as type III receptors), or components of the SMAD-dependent canonical pathway including regulatory or inhibitory SMAD proteins, or members of the SMAD-independent or non-canonical pathways including various branches of MAPK signaling, TAK1, Rho-like GTPase signaling pathways, phosphatidylinositol-3 kinase/AKT pathways, 5 TGF β -induced EMT process, or canonical and non-canonical Hedgehog signaling pathways including Hh ligands or target genes, or any members of the WNT, or Notch pathways which are susceptible to influence TGF β signaling.

Alternatively, the synergistic combination according to the invention may further 10 comprise at least one therapeutically active agent selected from JAK/STAT inhibitors and other anti-inflammatory agents and/or immunosuppressant agents. For example, the therapeutically active agent may be selected from glucocorticoids, NSAIDs, cyclophosphamide, nitrosoureas, folic acid analogs, purine analogs, pyrimidine analogs, methotrexate, azathioprine, mercaptopurine, ciclosporin, myriocin, tacrolimus, sirolimus, 15 mycophenolic acid derivatives, fingolimod and other sphingosine-1-phosphate receptor modulators, monoclonal and/or polyclonal antibodies against such targets as proinflammatory cytokines and proinflammatory cytokine receptors, T-cell receptor and integrins.

20 The present invention also relates to the synergistic combination according to the invention, for use as a medicament.

Furthermore, the invention relates to the synergistic combination described herein, for use in a method for treating a fibrotic disorder. In a particular embodiment, the fibrotic 25 disorder is selected in the group consisting of liver, gut, kidney, skin, epidermis, endodermis, muscle, tendon, cartilage, heart, pancreas, lung, uterus, nervous system, testis, penis, ovary, adrenal gland, artery, vein, colon, intestine (e.g. small intestine), biliary tract, soft tissue (e.g. mediastinum or retroperitoneum), bone marrow, joint, eye and stomach fibrosis. In a further particular embodiment, the fibrotic disorder is selected in the group consisting of liver, kidney, 30 skin, epidermis, endodermis, muscle, tendon, cartilage, heart, pancreas, lung, uterus, nervous system, testis, ovary, adrenal gland, artery, vein, colon, intestine (e.g. small intestine), biliary tract, soft tissue (e.g. mediastinum or retroperitoneum), bone marrow, joint and stomach fibrosis. In a further particular embodiment, the fibrotic disorder is selected in the group consisting of liver, gut, lung, heart, kidney, muscle, skin, soft tissue, bone marrow, 35 intestinal, and joint fibrosis. In yet another embodiment the fibrotic disorder is selected in the group consisting of non-alcoholic steatohepatitis (NASH), pulmonary fibrosis, idiopathic

pulmonary fibrosis, skin fibrosis, eye fibrosis (such as capsular fibrosis), endomyocardial fibrosis, mediastinal fibrosis, myelofibrosis, retroperitoneal fibrosis, progressive massive fibrosis (a complication of coal workers' pneumoconiosis), proliferative fibrosis, neoplastic fibrosis, lung fibrosis consecutive to chronic inflammatory airway disease (COPD, asthma, emphysema, smoker's lung, tuberculosis), alcohol or drug-induced liver fibrosis, liver cirrhosis, infection-induced liver fibrosis, radiation or chemotherapeutic-induced fibrosis, nephrogenic systemic fibrosis, Crohn's disease, ulcerative colitis, keloid, old myocardial infarction, scleroderma/systemic sclerosis, arthrofibrosis, some forms of adhesive capsulitis, chronic fibrosing cholangiopathies such as Primary Sclerosing Cholangitis (PSC), Primary Biliary Cholangitis (PBC), biliary atresia, familial intrahepatic cholestasis type 3 (PFIC3), peri-implantational fibrosis and asbestosis.

According to a particular embodiment of the invention, the choleststatic disease is selected in the group consisting of primary biliary cholangitis (PBC), primary sclerosing cholangitis (PSC), Intrahepatic Cholestasis of Pregnancy, Progressive Familial Intrahepatic Cholestasis, Biliary atresia, Cholelithiasis, Infectious Cholangitis, Cholangitis associated with Langerhans cell histiocytosis, Alagille syndrome, Nonsyndromic ductal paucity, Drug-induced cholestasis, and Total parenteral nutrition-associated cholestasis. In a particular embodiment, the choleststatic disease is PBC.

According to a particular embodiment, in each aspects and embodiments described herein, NTZ, NTZ-D or TZ, or a pharmaceutically acceptable salt of NTZ; NTZ-D or TZ is used.

DESCRIPTION OF THE FIGURES AND TABLES

Abbreviations used in the figures, in the tables, and in the text:

- α -SMA:** alpha Smooth Muscle Actin
- ATORVA:** Atorvastatin
- BDL:** Bile Duct Ligation
- BMP:** Bone Morphogenetic Protein
- cDNA:** Complementary Deoxyribonucleotide acid
- COL1A1:** Collagen, type 1, Alpha 1
- CDAA:** Choline-Deficient L-Amino Acid
- CDAAc:** Choline-Deficient L-Amino Acid-defined diet supplemented with cholesterol
- CHOL:** cholesterol
- CSAA:** Choline Supplemented L-Amino Acid-defined
- DDC:** 3,5-diethoxycarbonyl-1,4-dihydrocollidine

- DMSO**: Dimethyl sulfoxide
DTT: Dithiothreitol
ELISA: Enzyme-Linked Immunosorbent Assay
EMT: Epithelial-mesenchymal transition
- 5 **EOB**: Excess Over Bliss
FBS: Fetal Bovine Serum
FDA: Food and Drug Administration
FLUVA: Fluvastatin
FPP: Farnesyl Pyrophosphate
- 10 **GDF**: Growth Differentiation Factors
Hh: Hedgehog
GGPP: Geranylgeranylpyrophosphate
HMG-CoA: 3-hydroxy-3-méthylglutaryl-coenzyme A
hHSC: Human Hepatic Stellate Cells
- 15 **HSC**: Hepatic Stellate Cells
IC₅₀: Half maximal Inhibitory Concentration
InMyoFib: Intestinal Myofibroblasts
MMP2: Matrix Metalloproteinase 2
MMP9: Matrix Metalloproteinase 9
- 20 **μl**: microliter
LDL: Low Density Lipoprotein
LOVA: Lovastatin
NHLF: Normal Human Lung Fibroblasts
NTZ: Nitazoxanide
- 25 **PBC**: Primary Biliary Cholangitis
PBS: Phosphate Buffer Saline
PITA: Pitavastatin
PSC: Primary Sclerosing Cholangitis
qPCR: Quantitative Polymerase Chain Reaction
- 30 **pMol**: picomoles
PRAVA: Pravastatin
rhFGF: recombinant human basic Fibroblast Growth Factor
ROSU: Rosuvastatin
RNA: Ribonucleic Acid
- 35 **RT**: Reverse Transcriptase
SIMVA: Simvastatin

SmBM: Smooth Muscle cell Basal Medium

SteCGS: Stellate Cell Growth Supplement

STeCM: Stellate Cell Medium

TBA: Total Bile Acids

5 **TGFβ1:** Tumor Growth Factor beta 1

TGFBRI: TGFβ type I receptor

TGFBRII: TGFβ type II receptor

THBS1: Thrombospondine 1

TMB: Tetramethylbenzidine

10 **TZ:** Tizoxanide

TZG: Tizoxanide glucuronide

Figure 1: Nitazoxanide and its metabolite Tizoxanide inhibit TGFβ1-induced expression of α-SMA protein in human HSC

15 Serum-deprived HSC were preincubated for 1 hour with NTZ (A) or TZ (B) before the activation with the profibrogenic cytokine TGFβ1 (1 ng/ml). After 48 hours of incubation, the expression of α-SMA was measured by ELISA. The obtained values were transformed into percentage inhibition over TGFβ1 control. Data are presented as mean (triplicates) ± standard deviation (SD). Statistical analyses were performed by one-way ANOVA followed
20 by Bonferroni post-hoc tests, using Sigma Plot 11.0 software. [*: p<0.05; **: p<0.01; ***: p<0.001 (comparison versus TGFβ1 1ng/mL group)]. The curve fitting and the calculation of half maximal inhibitory concentration (IC₅₀) were performed with XLFit software 5.3.1.3.

Figure 2: Differential antifibrotic effect of statin drugs in TGFβ-induced hHSC

25 Serum-deprived hHSC were preincubated for 1 hour with Pitavastatin (A), Fluvastatin (B), Simvastatin (C), Atorvastatin (D), Lovastatin (E), Rosuvastatin (F) and Pravastatin (G) before the activation with the profibrogenic cytokine TGFβ1 (1ng/ml). After 48 hours of incubation, the expression of α-SMA was measured by ELISA. The obtained values were transformed into percentage inhibition over TGFβ1 control. Data are presented as mean (triplicates) ±
30 standard deviation (SD). Statistical analyses were performed by one-way ANOVA followed by Bonferroni post-hoc tests, using Sigma Plot 11.0 software. [*: p<0.05; **: p<0.01; ***: p<0.001 (comparison versus TGFβ1 1ng/mL group)]. The curve fitting and the calculation of half maximal inhibitory concentration (IC₅₀) were performed with XLFit software 5.3.1.3.

35 Figure 3: Combination of NTZ and Pitavastatin synergistically inhibits α-SMA in TGFβ1-induced hHSC

Combinations were tested in a dose-response matrix format and analyzed according to the excess over Bliss (EOB) additivism model. Dilution series of NTZ (column) and Pitavastatin (row) were prepared, including their respective DMSO controls. The resulting mixes were added to serum-deprived HSC, 1 hour prior to the activation with the profibrogenic cytokine TGF β 1 (1 ng/ml). (A) Percentage of α -SMA inhibition over the TGF β 1 control for all combination pairs. Data are presented as mean of quadruplicates. (B) EOB scores were calculated as described in Materials and Methods. Any compound pair with positive EOB values was considered synergistic (colored from light grey to black). (C) Data values derived from a synergistic combination pair were plotted in a bar graph representation. Data are presented as mean (quadruplicates) $\pm$ standard deviation (SD). Statistical analyses between single agent vs product combination were performed by student t-test or Mann-Whitney Rank Sum Test using Sigma Plot 11.0 software. [*: $p < 0.05$; **: $p < 0.01$; ***: $p < 0.001$].

Figure 4: Combination of NTZ and Simvastatin synergistically inhibits α -SMA in TGF β -induced hHSC

Combinations were tested in a dose-response matrix format and analyzed according to the excess over Bliss (EOB) additivism model. Dilution series of NTZ (column) and Simvastatin (row) were prepared, including their respective DMSO controls. The resulting mixes were added to serum-deprived HSC 1 hour prior to the activation with the profibrogenic cytokine TGF β 1 (1 ng/ml). (A) Percentage of α -SMA inhibition over the TGF β 1 control for all combinations. (B) EOB scores were calculated as described in Materials and Methods. Any compound pair with positive EOB values was considered synergistic (colored from light grey to black). (C) Data values derived from a synergistic combination pair were plotted in a bar graph representation. Data are presented as mean (quadruplicates) $\pm$ standard deviation (SD). DETAILED DESCRIPTION OF THE INVENTION

5 In the experimental part of the present application, it is shown that a combination of (i) NTZ, or TZ, with (ii) a statin may synergistically confer antifibrotic properties in activated myofibroblasts. Moreover, it is shown that combinations of (i) NTZ or TZ, with (ii) a statin can also reduce altered levels of total biliary acids in a model of liver injury. Accordingly, the present invention relates to a novel synergistic combination of active agents, comprising (i) 10 NTZ or a derivative of NTZ such as a deuterated derivative of NTZ (NTZ-D), TZ or TZG, or a pharmaceutically acceptable salt of NTZ, NTZ-D, TZ or of TZG, and (ii) a statin.

In particular, the present invention relates to the synergistic combination of (i) NTZ, a deuterated derivative of NTZ, or TZ, or a pharmaceutically acceptable salt of NTZ, of TZ, or of a deuterated derivative of NTZ, and (ii) a statin, for use in a method for the treatment of a 15 cholestatic or fibrotic disorder.

Furthermore, the invention relates to the use of the synergistic combination of the invention, comprising (i) NTZ, NTZ-D, TZ or of TZG, or a pharmaceutically acceptable salt of NTZ, NTZ-D, TZ or of TZG, and (ii) a statin, for the manufacture of a medicament useful for the treatment of a cholestatic and fibrotic disorder. The invention also relates to a 20 pharmaceutical composition comprising (i) NTZ, NTZ-D, TZ or of TZG, or a pharmaceutically acceptable salt of NTZ, NTZ-D, TZ or TZG, and (ii) a statin, said components (i) and (ii) acting synergistically as described herein. The pharmaceutical composition according to the invention is useful for treating a cholestatic or fibrotic disorder.

Although the causative agents or initiating events of fibrotic disorders are quite diverse 25 and their pathogenesis is variable, a common feature in affected tissues is the presence of large numbers of activated fibroblasts called myofibroblasts ((Rosenbloom, Mendoza *et al.*, 2013)). Fibrotic stimulus such as TGF β 1 can induce differentiation of fibroblasts to myofibroblasts (Leask and Abraham, 2004; Leask, 2007). Myofibroblasts are metabolically and morphologically distinctive fibroblasts whose activation play a key role during the fibrotic 30 response. Furthermore, these myofibroblasts display unique biological functions including expression of proteins involved in extracellular matrix formation such as different forms of collagen. The induction of α -smooth muscle actin (α -SMA) expression is a recognized hallmark of quiescent fibroblast to activated myofibroblast differentiation and can be used as a physiological read-out to evaluate the potency of the drugs that interfere with the fibrotic 35 process. Tumor Growth β factors, and especially the Tumor Growth Factor beta 1 (TGF β 1) are recognized physiological signals that induce the phenotypic transformation of fibroblasts

NTZ and TZ(G) ("TZ(G)" referring to "TZ or TZG")) were known for their antiparasitic and antiviral activities, but the prior art does not teach NTZ, and TZ(G) have anticholestatic and anti-fibrotic effect.

The inventors have demonstrated in a new and inventive way that these compounds
5 have a therapeutic effect in the treatment of cholestasis or fibrosis.

The prior art does neither teach that deuterated derivatives of NTZ (also referred to elsewhere in this application as "NTZ-D") have anticholestatic or anti-fibrotic effects.

According to the present invention, deuterated derivatives of NTZ to be used in the composition according to the invention have the following Formula (IV):

10

wherein R2 represents a group wherein, R2a, R2b and R2c, identical or different, represent a hydrogen atom or a deuterium atom, with the proviso that R2a, R2b,
15 R2c are not simultaneously a hydrogen atom.

In a particular embodiment, R2a, R2b and R2c represent a deuterium atom.

In a particular embodiment, R2a and R2b represent a deuterium atom, R2c represents a hydrogen atom.

In a particular embodiment, R2a represents a deuterium atom, R2b and R2c represent
20 a deuterium atom.

Examples of such compounds of the invention include :

Cpd.1 : 2-[(5-nitro-1,3-thiazol-2-yl)carbamoyl]phenyl (d3)ethanoate;

Cpd.2 : 2-[(5-nitro-1,3-thiazol-2-yl)carbamoyl]phenyl (d2) ethanoate; and

Cpd.3 : 2-[(5-nitro-1,3-thiazol-2-yl)carbamoyl]phenyl (d1) ethanoate;

25

In the context of the present invention, "NTZ, NTZ-D and TZ(G), and pharmaceutically acceptable salts of NTZ, NTZ-D and TZ(G)" or "compound of formula (I), (II), (III) and (IV),

and pharmaceutically acceptable salts of compound of formula (I), (II), (III) and (IV)" are collectively referred to as "component (i)" or "component (i) of the combination".

In the context of the present invention, "component (ii)" or "component (ii) of the combination" refers to "at least one statin" or "a statin".

5 The inventors have also demonstrated in a new and inventive way that the combination of NTZ, NTZ-D, TZ(G) with a statin may have a synergistic anticholestatic and/or anti-fibrotic effect in human HSCs.

10 In the present invention, synergism is defined by a coordinated or correlated action of two or more structures so that the combined action is greater than the sum of each acting separately.

Accordingly, the invention relates to the synergistic combination of (i) NTZ, NTZ-D, TZG, or a pharmaceutically acceptable salt of NTZ, NTZ-D or TZ(G), with (ii) a statin. The invention further relates to this combination, for use in a method for the treatment of a cholestatic or fibrotic disorder.

15 According to a particular embodiment of the invention, the combination comprises (i) NTZ, NTZ-D or TZ, or a pharmaceutically acceptable salt of NTZE, NTZ-D or TZ, and (ii) a statin.

20 In a further aspect, the invention relates to the synergistic combination of the invention, for use in the inhibition of proliferation and/or activation of fibroblasts. As is known in the art, fibroblasts are responsible for the production of collagen fibers or other connective tissue components of the extracellular matrix.

25 According to the present invention, the terms "fibrosis", "fibrotic disease", "fibrotic disorder" and declinations thereof denote a pathological condition of excessive deposition of fibrous connective tissue in an organ or tissue. More specifically, fibrosis is a pathological process, which includes a persistent fibrotic scar formation and overproduction of extracellular matrix, by the connective tissue, as a response to tissue damage. Physiologically, the deposit of connective tissue can obliterate the architecture and function of the underlying organ or tissue.

30 According to the present invention, the fibrosis or fibrotic disorder may be associated with any organ or tissue fibrosis. Illustrative, non-limiting examples of particular organ fibrosis include liver, gut, kidney, skin, epidermis, endodermis, muscle, tendon, cartilage, heart, pancreas, lung, uterus, nervous system, testis, penis, ovary, adrenal gland, artery, vein, colon, intestine (e.g. small intestine), biliary tract, soft tissue (e.g. mediastinum or retroperitoneum), bone marrow, joint, eye or stomach fibrosis, in particular liver, kidney, skin, 35 epidermis, endodermis, muscle, tendon, cartilage, heart, pancreas, lung, uterus, nervous system, testis, ovary, adrenal gland, artery, vein, colon, intestine (e.g. small intestine), biliary

tract, soft tissue (e.g. mediastinum or retroperitoneum), bone marrow, joint or stomach fibrosis.

According to the present invention, the terms "cholestasis" or "cholestatic disease", or "cholestatic disorder" and declinations thereof denote a pathological condition defined by a decrease in bile flow due to impaired secretion by hepatocytes or to obstruction of bile flow through intra- or extrahepatic bile ducts. Therefore, the clinical definition of cholestasis is any condition in which substances normally excreted into bile are retained.

In a particular embodiment, the fibrotic disorder is selected in the group consisting of a liver, gut, lung, heart, kidney, muscle, skin, soft tissue (e.g. mediastinum or retroperitoneum), bone marrow, intestinal, and joint (e.g. knee, shoulder or other joints) fibrosis.

In a preferred embodiment, the fibrotic disorder is selected in the group consisting of the liver, lung, skin, kidney and intestinal fibrosis.

In a more preferred embodiment of the present invention, treated fibrotic disorder is selected in the group consisting of the following non exhaustive list of fibrotic disorders: non-alcoholic steatohepatitis (NASH), pulmonary fibrosis, idiopathic pulmonary fibrosis, skin fibrosis, eye fibrosis, endomyocardial fibrosis, mediastinal fibrosis, myelofibrosis, retroperitoneal fibrosis, progressive massive fibrosis (a complication of coal workers' pneumoconiosis), proliferative fibrosis, neoplastic fibrosis, lung fibrosis consecutive to chronic inflammatory airway disease (COPD, asthma, emphysema, smoker's lung, tuberculosis), alcohol or drug-induced liver fibrosis, liver cirrhosis, infection-induced liver fibrosis, radiation or chemotherapeutic-induced fibrosis, nephrogenic systemic fibrosis, Crohn's disease, ulcerative colitis, keloïd, old myocardial infarction, scleroderma/systemic sclerosis, arthrofibrosis, some forms of adhesive capsulitis, chronic fibrosing cholangiopathies such as Primary Sclerosing Cholangitis (PSC) and Primary Biliary Cholangitis (PBC), biliary atresia, familial intrahepatic cholestasis type 3 (PFIC3), peri-implantational fibrosis and asbestosis.

According to a particular embodiment of the invention, the choleststatic disease is selected in the group consisting of primary biliary cholangitis (PBC), primary sclerosing cholangitis (PSC), Intrahepatic Cholestasis of Pregnancy, Progressive Familial Intrahepatic Cholestasis, Biliary atresia, Cholelithiasis, Infectious Cholangitis, Cholangitis associated with Langerhans cell histiocytosis, Alagille syndrome, Nonsyndromic ductal paucity, Drug-induced cholestasis, and Total parenteral nutrition-associated cholestasis. In a preferred embodiment, the cholestatic disease is PBC or PSC, in particular PBC.

The term "treatment" or "treating" refers to the curative or preventive of a cholestatic or fibrotic disorder in a subject in need thereof. The treatment involves the administration of the combination of the invention to a subject having a declared disorder, i.e. to a patient, to cure,

delay, reverse, or slow down the progression of the disorder, improving thereby the condition of the subject. A treatment may also be administered to a subject that is healthy or at risk of developing a cholestatic or fibrotic disorder to prevent or delay the disorder.

Therefore, according to the invention, the treatment of a fibrotic disorder involves the administration of the combination of the present invention, for example in the form of a pharmaceutical composition containing components (i) and (ii) of the combination, to a subject having a declared disorder to cure, delay, reverse or slow down the progression of the disorder, thus improving the condition of the patient or to a healthy subject, in particular a subject who is at risk of developing a cholestatic or fibrotic disorder.

The subject to be treated is a mammal, preferably a human. The subject to be treated according to the invention can be selected on the basis of several criteria associated with cholestatic or fibrotic diseases such as previous drug treatments, associated pathologies, genotype, exposure to risk factors, viral infection, as well as on the basis of the detection of any relevant biomarker that can be evaluated by means of imaging methods and immunological, biochemical, enzymatic, chemical, or nucleic acid detection methods.

According to the present invention, the term "statin(s)" refers the HMG-CoA reductase inhibitors, which are a class of cholesterol lowering drugs that inhibit the enzyme HMG-CoA reductase, which plays a central role in the production of cholesterol. Elevated blood cholesterol levels have been associated with cardiovascular disease (CVD), and many studies have shown that the risk of CVD events can be reduced by lipid-lowering therapy. At the beginning, the lipid-lowering armamentarium was limited essentially to a low saturated fat and cholesterol diet, bile acid sequestrants (cholestyramine and colestipol), nicotinic acid (niacin), fibrates and probucol. Unfortunately, all of these treatments have limited efficacy or tolerability, or both.

The HMG-CoA reductase inhibitors described above belong to a structural class of compounds which contain a moiety which can exist as either a 3-hydroxy lactone ring or as the corresponding ring opened dihydroxy open-acid. Salts of the dihydroxy open-acid can be prepared, and in fact, as noted above, several of the marketed statins are administered as the dihydroxy open acid salt forms.

For example, lovastatin and simvastatin are marketed worldwide in their lactonized form.

Statins have been found to reduce cardiovascular disease and mortality in those who are at high risk. The evidence is strong that statins are effective for treating CVD in the early stages of a disease (secondary prevention) and in those at elevated risk but without CVD (primary prevention).

According to the invention, the term "statin(s)" as used herein includes, but is not limited to fluvastatin, atorvastatin, mevastatin, cerivastatin, lovastatin, simvastatin, rosuvastatin, pravastatin, and pitavastatin. According to a particular embodiment of the invention, the statin is selected from pitavastatin, fluvastatin, simvastatin and atorvastatin.

5 Statins may be in the form of a salt, hydrate, solvate, polymorph, or a co-crystal. Statins may also be in the form of a hydrate, solvate, polymorph, or a co-crystal of a salt. Statins may also be present in the free acid or lactone form according to the present invention.

10 Component (ii) of the combination may comprise one or more statin, i.e. one statin or a mixture of statins.

 According to the invention the statin comprised in the combination of the invention is selected so that the combination of said statin and component (i) of the combination of the invention provides a synergistic action against cholestasis or fibrosis. Such synergy may be determined according to methods well-known in the art, such as by using the Excess Over Bliss (EOB) method described in the examples.

15 In a preferred embodiment, the statin in the synergistic combination of the present invention is selected in the group consisting of lovastatin, rosuvastatin, pravastatin, pitavastatin, fluvastatin, simvastatin and atorvastatin, in particular in the group consisting of pitavastatin, fluvastatin and simvastatin.

20 Another aspect of the invention relates to the synergistic combination described above in the form of a pharmaceutical composition. Therefore, the invention also relates to a pharmaceutical composition comprising (i) NTZ, NTZ-D or TZ(G), or a pharmaceutically acceptable salt of NTZ, NTZ-D or TZ(G), and (ii) a statin.

 In yet another aspect, the present invention relates to the synergistic combination described above, in the form of a kit-of-parts for the simultaneous, sequential or separate administration of its components, as described in more details below.

 The invention provides also a method of treatment of cholestasis or fibrosis.

30 The treatment involves the administration of the synergistic combination of the invention to a patient having a declared disorder to cure, delay, or slow down the progress, thus improving the condition of the patient or to a healthy subject, in particular a subject who is at risk of developing a cholestatic or fibrotic disease, to prevent the disease.

 The subjects to be treated according to the invention can be selected on the basis of several criteria associated to fibrotic diseases such as previous drug treatments, associated pathologies, genotype, exposure to risk factors, viral infection, as well as any other relevant biomarker that can be evaluated by means of imaging methods and immunological, biochemical, enzymatic, chemical, or nucleic acid detection method.

35

Synthesis of NTZ or TZ can be for example carried out as described in (Rossignol and Cavier, 1975), or by any other way of synthesis known by a person skilled in the art. TZG can be, for example, synthesized according to way of synthesis known in the art such as in Wadouachi 2011. S'agit-il de A Wadouachi, J Kovensky, Synthesis of Glycosides of
5 Glucuronic, Galacturonic and Mannuronic Acids: An Overview, Molecules, 2011, 16(5), 3933-3968.

In a particular embodiment, the treatment of a cholestatic or fibrotic disorder may comprise the administration of a composition comprising at least two compounds selected from NTZ, NTZ-D and TZ(G). In this embodiment, the administered statin is provided in the
10 same composition as the two compounds, or in a separate form, such as in a different composition.

In another embodiment, the synergistic combination of the invention is for simultaneous, sequential or separate administration in therapy, therefore being possibly included in different compositions. In case of sequential administration, component (i) of the
15 combination may be administrated prior to component (ii), or component (ii) is administrated prior to component (i). As such, the invention also relates to kit-of-parts comprising the synergistic combination of (i) NTZ, NTZ-D and TZ(G), or a pharmaceutically acceptable salt of NTZ, NTZ-D and TZ(G), ; and (ii) a statin, , for simultaneous, sequential or separate administration.

20 NTZ, NTZ-D, TZ(G) and a statin can be formulated as pharmaceutically acceptable salts, particularly acid or base salts compatible with pharmaceutical use. Salts of NTZ, NTZ-D, TZ(G) and a statin include pharmaceutically acceptable acid addition salts, pharmaceutically acceptable base addition salts, pharmaceutically acceptable metal salts, ammonium and alkylated ammonium salts. These salts can be obtained during the final
25 purification step of the compound or by incorporating the salt into the previously purified compound.

Combination of a components (i) and (ii), in particular of a compound of Formula (I), (II), (III) or (IV) with one or more statin(s) can be formulated as pharmaceutically acceptable non-toxic salts obtained from organic or inorganic bases or acids of compound of Formula (I), (II),
30 (III) (IV) or statin(s). These salts can be obtained during the final purification step of the compound or by incorporating the salt into the previously purified compound.

The pharmaceutical compositions of the present invention comprising component (i) and/or (ii), in particular comprising a compound of Formula (I), (II), (III) and/or one or more statin(s) can also comprise one or several excipients or vehicles, acceptable within a
35 pharmaceutical context (e.g. saline solutions, physiological solutions, isotonic solutions, etc., compatible with pharmaceutical usage and well-known by one of ordinary skill in the art).

These compositions can also comprise one or several agents or vehicles chosen among dispersants, solubilisers, stabilisers, preservatives, etc. Agents or vehicles useful for these formulations (liquid and/or injectable and/or solid) are particularly methylcellulose, hydroxymethylcellulose, carboxymethylcellulose, polysorbate 80, mannitol, gelatin, lactose, vegetable oils, acacia, liposomes, etc.

These compositions can be formulated in the form of injectable suspensions, gels, oils, ointments, pills, tablets, suppositories, powders, gel caps, capsules, aerosols, etc., eventually by means of galenic forms or devices assuring a prolonged and/or slow release. For this kind of formulation, agents such as cellulose, carbonates or starches can be advantageously used.

The pharmaceutical compositions of the present invention comprising component (i) and/or (ii) of the combination, such as a compound of Formula (I), (II), (III) and/or one or more statin(s) (the statin being selected, as mentioned above, among those that allows a synergistic effect with component (i) of the combination of the present invention) may be administered by different routes and in different forms. For example, the compound(s) may be administered via a systemic way, per os, parenterally, by inhalation, by nasal spray, by nasal instillation, or by injection, such as for example intravenously, by intra-muscular route, by subcutaneous route, by transdermal route, by topical route, by intra-arterial route, etc.

Of course, the route of administration will be adapted to the form of component (i) in combination with one or more statin(s) according to procedures well known by those skilled in the art.

In a particular embodiment, the component(s) (i) and (ii) are formulated as a tablet or as tables. In another particular embodiment, the compounds are administered orally.

NTZ, NTZ-D or TZ(G) in combination with one or more statin(s) is administered in a therapeutically effective amount. Within the context of the invention, the term "effective amount" refers to an amount of the compound sufficient to produce the desired therapeutic result.

The frequency and/or dose relative to the administration can be adapted by one of ordinary skill in the art, in function of the patient, the pathology, the form of administration, etc. Typically, the combination (such as in the form of a pharmaceutical composition or a kit-of-parts) of the present invention can be administered for the treatment of a cholestatic or fibrotic disease at a dose for component (i) of the combination comprised between 0.01 mg/day to 4000 mg/day, such as from 50 mg/day to 2000 mg/day, such as from 100 mg/day to 2000 mg/day; and particularly from 100 mg/day to 1000 mg/day. In a particular embodiment, the NTZ, TZ(G), or a pharmaceutically acceptable salt thereof, is administered at a dose of about 1000 mg/day (i.e at a dose of 900 to 1100 mg/day), in particular at 1000

mg/day. In a particular embodiment, NTZ, TZ(G), or a pharmaceutically acceptable salt thereof, is administered orally at a dose of about 1000 mg/day, in particular at 1000 mg/day, in particular as a tablet. Administration can be performed daily or even several times per day, if necessary. In one embodiment, the compound is administered at least once a day, such as
5 once a day, twice a day, or three times a day. In a particular embodiment, the compound is administered once or twice a day. In particular, oral administration may be performed once a day, during a meal, for example during breakfast, lunch or dinner, by taking a tablet comprising the compound at a dose of about 1000 mg, in particular at a dose of 1000 mg. In another embodiment, a tablet is orally administered twice a day, such as by administering a
10 first tablet comprising the compound at a dose of about 500 mg (i.e. at a dose of 450 to 550 mg), in particular at a dose of 500 mg, during one meal, and administering a second tablet comprising the compound at a dose of about 500 mg, in particular at a dose of 500 mg, during another meal the same day.

The dose of the statin in the said combination may vary according to the statin itself.
15 The dose is adapted to the efficiency of the statin according to typical statin regimen.

For example, for Fluvastatin, the dose may be comprised between 10 to 50 mg/day, and particularly from 20 to 40 mg/day.

For pitavastatin the dose may be comprised between 0,1 mg/day to 6 mg/day, and particularly from 1 to 4 mg/day.

20 For both Simvastatin and Atorvastatin, the dose may be comprised between 1 mg/day to 100 mg/day, and particularly from 10 to 80 mg/day.

In a preferred embodiment of the invention, component (i), in particular NTZ, is used in combination with fluvastatin at a dose comprised between 100 mg/day to 1000 mg/day for NTZ and 1 to 4 mg/day for fluvastatin.

25 In another preferred embodiment of the invention, component (i), in particular NTZ, is used in combination with pitavastatin at a dose comprised between 100 mg/day to 1000 mg/day for NTZ and 1 to 4 mg/day for pitavastatin.

In another preferred embodiment of the invention, component (i), in particular NTZ, is used in combination with Simvastatin or Atorvastatin at a dose comprised between 100
30 mg/day to 1000 mg/day for NTZ and 10 to 80 mg/day for Simvastatin and Atorvastatin.

In another preferred embodiment, the active ingredients are administered as one or more pharmaceutical composition(s) in the form of a pill or tablet intended for an oral ingestion.

Administration can be performed daily or even several times per day, if necessary.
35 Suitably, the course of treatment with the combination of the invention is for at least 1 week, in particular for at least 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20 or 24 weeks or more. In

particular, the course of treatment with NTZ, TZ(G) or a pharmaceutically acceptable salt thereof is for at least 1 year, 2 years, 3 years, 4 years or at least 5 years.

In a particular embodiment, the invention relates to the treatment of a cholestatic or fibrotic disease, in particular liver fibrosis, more particularly liver fibrosis consecutive to NASH, in a patient in need thereof, comprising administering to said patient a therapeutically effective amount of the combination of the invention, including in particular administering NTZ at a dose of 1000 mg/day, in particular by administering a tablet containing 500 mg of NTZ twice a day, in particular during two different meals.

In a particular embodiment, the invention relates to a combination of the present invention, further combined to at least one other therapeutically active agent, such as other molecules with known antifibrotic activity. This further combination of the present invention is useful for the treatment of a cholestatic or fibrotic disorder.

According to a variant of this embodiment, NTZ, TZ or a deuterated derivative of NTZ in combination with one or more statin(s) can be combined with any antifibrotic compound such as pirfenidone or receptor tyrosine kinase inhibitors (RTKIs) such as Nintedanib, sorafenib and other RTKIs, or angiotensin II (AT1) receptor blockers, or CTGF inhibitor, or any antifibrotic compound susceptible to interfere with the TGF β - and BMP-activated pathways including activators of the latent TGF β complex such as MMP2, MMP9, THBS1 or cell-surface integrins, TGF β receptors type I (TGFBRI) or type II (TGFBRII) and their ligands such as TGF β , Activin, inhibin, Nodal, anti-Müllerian hormone, GDFs or BMPs, auxiliary co-receptors (also known as type III receptors), or components of the SMAD-dependent canonical pathway including regulatory or inhibitory SMAD proteins, or members of the SMAD-independent or non-canonical pathways including various branches of MAPK signaling, TAK1, Rho-like GTPase signaling pathways, phosphatidylinositol-3 kinase/AKT pathways, TGF β -induced EMT process or canonical and non-canonical Hedgehog signaling pathways including Hh ligands or target genes, or any members of the WNT, or Notch pathways which are susceptible to influence TGF β signaling.

Thus, the invention also relates to a pharmaceutical composition, in particular for its use in a method for the treatment of a cholestatic or fibrotic disease, comprising a compound selected from component (i) with component (ii), in combination with at least one therapeutically active agent with known antifibrotic activity selected from pirfenidone or receptor tyrosine kinase inhibitors (RTKIs) such as Nintedanib, sorafenib and other RTKIs, or angiotensin II (AT1) receptor blockers, or CTGF inhibitor, or antifibrotic compound susceptible to interfere with the TGF β - and BMP-activated pathways including activators of the latent TGF β complex such as MMP2, MMP9, THBS1 or cell-surface integrins, TGF β

receptors type I (TGFBRI) or type II (TGFBRII) and their ligands such as TGF β , Activin, inhibin, Nodal, anti-Müllerian hormone, GDFs or BMPs, auxiliary co-receptors (also known as type III receptors), or components of the SMAD-dependent canonical pathway including regulatory or inhibitory SMAD proteins, or members of the SMAD-independent or non-canonical pathways including various branches of MAPK signaling, TAK1, Rho-like GTPase signaling pathways, phosphatidylinositol-3 kinase/AKT pathways, TGF β -induced EMT process, or canonical and non-canonical Hedgehog signaling pathways including Hh ligands or target genes, or any members of the WNT, or Notch pathways which are susceptible to influence TGF β signaling, for use in a method for treating a cholestatic or fibrotic disorder.

In another particular embodiment, other classes of molecules that could also be combined with component (i) and component (ii) include JAK/STAT inhibitors, or other anti-inflammatory and/or immunosuppressant agents. The non exhaustive list of these agents includes but is not limited to glucocorticoids, NSAIDS, cyclophosphamide, nitrosoureas, folic acid analogs, purine analogs, pyrimidine analogs, methotrexate, azathioprine, mercaptopurine, ciclosporin, myriocin, tacrolimus, sirolimus, mycophenolic acid derivatives, fingolimod and other sphingosine-1-phosphate receptor modulators, monoclonal and/or polyclonal antibodies against such targets as proinflammatory cytokines and proinflammatory cytokine receptors, T-cell receptor, integrins. Other classes of molecules that could also be combined with component (i) and component (ii), include molecules that could potentially enhance the exposure or the effect of component (i) with component (ii).

In another embodiment, components (i) and (ii), are administered as the sole active ingredient.

In a further embodiment, the present invention provides methods of treating a cholestatic or fibrotic disease comprising the administration of the combination of the present invention, in particular in the form of a pharmaceutical composition or of a kit-of-parts containing component (i) and component (ii).

The invention is further described with reference to the following, non-limiting, examples.

EXAMPLES

MATERIALS AND METHODS

Compounds were dissolved in dimethyl sulfoxide (DMSO, Fluka cat# 41640). Nitazoxanide (INTERCHIM cat#RQ550U), tizoxanide (INTERCHIM cat#RP253) were obtained

commercially, as well as Pitavastatin (INTERCHIM cat#15414), Simvastatin (Sigma Aldrich cat #S6196), Fluvastatin (Sigma Aldrich cat#Y0001090), Pravastatin (Selleckchem cat #S3036), Rosuvastatin (Selleckchem cat#S2169), Lovastatin (Selleckchem cat#S4223), Atorvastatin (Sigma Aldrich cat#PZ0001).

5

hHSC culture

The human primary hepatic stellate cells (hHSC) (Innoprot) were cultured in STeCM medium (ScienCell cat# 5301) that was supplemented with 2% fetal bovine serum (FBS, ScienCell cat# 0010), 1% penicillin/streptomycin (ScienCell cat# 0503) and stellate cell growth supplement (SteCGS; ScienCell cat# 5352). Cell-culture flasks were coated with Poly-L Lysine (Sigma cat# P4707) for a better adherence.

10

Preparation of compositions

2 components combination matrix (NTZ/statin or TZ/statin)

The checkerboard matrix was adopted. NTZ or TZ and statin stocks were serially diluted in DMSO in a 5-points series in a row (statin) and a column (NTZ or TZ) of a 96-well plate. A 6th point was filled with 100% DMSO without compound. Subsequently, the 6X6 combination matrix was generated by 1:1 mixing of all single agent concentrations. The five test concentrations for each compound were chosen based on the respective IC₅₀ of each compound as single agent obtained by measuring α -SMA content in the HSC model stimulated with TGF- β 1. Then, 2-fold and 4-fold higher and lower concentrations were selected.

20

For Pravastatin and Rosuvastatin which were found inactive and weak inhibitor, respectively in TGF- β 1 stimulated HSC model, the dose range was selected arbitrarily (5 doses serially diluted 2 fold starting from 4 μ M).

25

Activation of hHSC with TGF- β 1 and compound treatment

The human primary hepatic stellate cells (hHSC) (Innoprot) were cultured under standard conditions, as described above. The cells were subsequently plated at a density of 2 x 10⁴ cells/well into 96-well plates for the measure of α -SMA by ELISA. The next day, cell culture medium was removed, and cells were washed with PBS (Invitrogen cat# 14190). hHSC were deprived for 24 hours in serum-free and SteCGS-free medium. For the treatments with NTZ, statins (Pitavastatin, Fluvastatin, Simvastatin, Atorvastatin, Lovastatin, Rosuvastatin, Pravastatin) and the respective NTZ/statin combinations and also for the treatment with TZ, statins (Pitavastatin, Simvastatin, Fluvastatin, Pravastatin) and the respective combinations TZ/statin, the serum-deprived hHSC were preincubated for 1 hour

30

35

with the compounds followed by the addition of the profibrogenic stimuli TGF- β 1 (PeproTech cat# 100-21, 1 ng/mL) in serum-free and SteCGS-free medium for an additional 48 hour period.

- At the end of treatment, cells were washed with PBS (Invitrogen, cat# 14190) before the
5 addition of 50 μ l of lysis buffer (CellLyticTM MT reagent; Sigma #C3228). Plates were then incubated for 30 min on ice using a plate shaker, before storage at -20°C.

α -SMA ELISA

- The level of α -SMA was measured using a Sandwich ELISA. Briefly, the wells of an ELISA
10 plate were first coated with the capture antibody (mouse monoclonal anti-ACTA2, Abnova) at 4°C overnight. After 3 washes in PBS + 0.2% Tween 20, a blocking solution consisting of PBS + 0.2% BSA was added for one hour followed by another washing cycle. The cell lysates were transferred into the wells for binding to the capture antibody for a period of 2h at room temperature. After the washing procedure, the detection antibody (biotinylated mouse
15 monoclonal anti-ACTA2, Abnova) was added for 2 hours at room temperature followed by 3 washes. For the detection, an HRP-conjugated Streptavidin (R&D Systems cat# DY998) was first applied for 30 min at room temperature. After washing, the HRP substrate TMB (;BD,#555214) was added and incubated for 7min at room temperature in the dark. Upon oxidation, TMB forms a water-soluble blue reaction product that becomes yellow with
20 addition of sulfuric acid (solution stop), enabling accurate measurement of the intensity at 450nm using a spectrophotometer. The developed color is directly proportional to the amount of α -SMA present in the lysate.

Determination of synergism by Excess Over Bliss (EOB) method

- 25 The values obtained in the α SMA ELISA assays were first transformed into percentage inhibitions over TGF- β 1 control. Then, using these percentage inhibitions converted into fractions (percentage divided by 100), EOB (Excess Over Bliss) was determined to define the synergistic effects of drug combinations. Expected Bliss additivism score (E) was firstly determined by the equation:
30 $E = (A + B) - (A \times B)$ where A and B are the percentage inhibitions converted into fractions within a range of 0 to 1 of NTZ (A) and a given statin (B) at a given dose. The difference between the Bliss expectation and the observed inhibition of the combined NTZ/statin at the same dose is the 'Excess over Bliss' score.
- Excess over Bliss score = 0 indicates that the combination treatment is additive (as
35 expected for independent pathway effects);

- Excess over Bliss score >0 indicates activity greater than additive (synergy); and
- Excess over Bliss score <0 indicates the combination is less than additive (antagonism).
For each product combination (NTZ + statin), an additional total Bliss score was calculated by summation of all EOB.

- 5 To validate the synergism, the experimental values corresponding to top EOB score for each NTZ/statin combination were plotted in a bar graph. The significance of the observed differences between NTZ/statin or TZ/statin and single agents were estimated by a student t-test or Mann-Whitney Rank Sum Test using Sigma Plot 11.0 software. [*: p<0.05; **: p<0.01; ***: p<0.001].

10

Evaluation of the synergistic therapeutic effect of NTZ /SIMVA combination in CCl4-induced liver fibrosis

The synergistic therapeutic effect of NTZ /SIMVA combination was assessed in a rat model of CCl4-induced liver injury.

- 15 OFA S;Dawley rats (initial body weight 250-275g) were randomized according to their body weight into 5 groups and treated for 3 weeks. The rats were intraperitoneally injected with olive oil (ctrl group) or with CCl4 emulsified in olive oil (CCl4: olive oil 1:2 v/v, final CCl4 concentration: 2ml/kg) twice weekly. Concomitantly, the olive oil injected group was placed on control diet while the CCl4 injected groups were placed on control diet or diet
20 supplemented with compounds. 3 regimen were prepared corresponding respectively to an exposure of NTZ 30 mg/kg/day, SIMVA 10 mg/kg/day or NTZ /SIMVA 30/10 mg/kg/day. The last day of treatment, the rats were sacrificed after a 6h fasting period. Blood samples were collected and the serum was isolated for biochemical analyses.

- 25 **Evaluation of the synergistic therapeutic effect of NTZ /SIMVA combination in a DDC-induced cholestasis model:**

The synergistic therapeutic effect of NTZ /SIMVA combination will be assessed in a DDC-induced cholestasis model

- 30 C57BL/6 mice will be fed for 8 weeks a 0,1% DDC-supplemented diet, or 0.1% DDC-supplemented diet corresponding respectively to an exposure of NTZ 100 mg/kg/day, or SIMVA 10 mg/kg/day or a standard mouse diet (Ssniff). The last day of treatment, the mice will be sacrificed after a 6h fasting period. Blood samples will be taken for biochemical analyses and liver will be rapidly excised for biochemical and histological studies.

Evaluation of the synergistic therapeutic effect of NTZ /SIMVA combination in a chronic CCl₄-induced liver fibrosis model

9 week-old C57BL/6 mice will be placed on control diet or diet supplemented with NTZ for 6 weeks. 8 diet regimen containing NTZ and/or SIMVA will be prepared corresponding
5 respectively to an exposure of NTZ at 30 or 100 mg/kg/day or SIMVA at 3 or 10 mg/kg/day or a combination of NTZ/SIMVA 30/3; 100/3; 30/10, 100/10 mg/kg/day, respectively... Concomitantly, and for the total duration of 6 weeks, the mice will be treated 3 times a week with CCl₄ dissolved in olive oil or vehicle by oral gavage. The amount of CCl₄ will be progressively increased from 0.875 ml/kg to 2.5 ml/kg. The last day of treatment, the mice will
10 be sacrificed after a 6h fasting period.. Blood samples will be collected and the serum will be isolated for biochemical analyses. The liver will be rapidly excised for biochemical, histological & expression studies.

Evaluation of the synergistic therapeutic effect of NTZ /SIMVA combination in a BDL model

Surgical bile duct ligation will be performed on rats in order to induce an extrahepatic cholestasis and subsequently liver fibrosis. After a short recovery period, animals will be treated with NTZ at 30 or 100 mg/kg/day, SIMVA at 3 or 10 mpk, or combinations of NTZ/SIMVA 30/3, or 100/10 mg/kg/day for one or two weeks. The last day of treatment, the
20 mice will be sacrificed after a 6h fasting period. Blood samples will be collected and the serum will be isolated for biochemical analyses. The liver will be rapidly excised for biochemical, histological & expression studies.

25 Measurement of plasmatic concentration of Total Bile Acids

The plasmatic concentration of Total Bile Acids (TBA) was determined using the appropriate Randox kit for the Daytona automated Analyzer (Randox, cat#BI 3863). In the presence of Thio-NAD, the enzyme 3- α hydroxysteroid dehydrogenase (3- α HSD) converts bile acids to 3-keto steroids and Thio-NADH. The reaction is reversible and 3- α HSD can convert 3-
30 ketosteroids and Thio-NADPH to bile acids and Thio-NAD. In the presence of excess NADH, the enzyme cycling occurs efficiently and the rate of formation of Thio-NADH is determined by measuring specific change of absorbance at 405nm. Results are expressed in μ mol/L.

Results and conclusions:

The abnormal persistence of differentiated myofibroblasts is a characteristic of many fibrotic diseases. Following liver injury, quiescent HSCs undergo a process of activation that is characterized by a differentiation into (α -SMA)-positive myofibroblasts. In an attempt to find new antifibrotic molecules, a library of FDA-approved drugs was phenotypically screened in a model of human HSC activated with the profibrogenic cytokine TGF- β 1. The level of α -SMA, a hallmark of fibrotic lesions, was used to evaluate the potency of the drugs to interfere with the fibrotic process. The screening campaign led to the identification of nitazoxanide (NTZ), which dose-dependently reduced the level of α -SMA in TGF β -induced HSCs. Overall, NTZ exhibited an IC₅₀ comprised between 0.1 and 3 μ M (Fig. 1A).

Since it is known that NTZ is rapidly hydrolyzed into its active metabolite tizoxanide (TZ) (Broekhuysen, Stockis *et al.*, 2000), this metabolite was also evaluated for its antifibrotic activity in HSC. TZ showed a profile similar to the parent drug with an IC₅₀ comprised between 0.1 and 3 μ M (Fig. 1B). Interestingly, specific statins but not all were also identified during the screening campaign. The dose-response analyses performed in the TGF β - induced HSC model (Fig. 2) reveal that the 7 tested statins are not equivalent regarding their antifibrotic properties.

Typically, Pitavastatin (Fig. 2A) and Fluvastatin (Fig. 2B), the most potent antifibrotic statins, exhibited an IC₅₀ below 1 μ M whereas the IC₅₀ values of Simvastatin (Fig. 2C), Atorvastatin (Fig. 2D), Lovastatin (Fig. 2E) were generally comprised between 1 and 3 μ M. Rosuvastatin (Fig. 2F) revealed a significant antifibrotic activity but only at the highest doses and Pravastatin (Fig. 2G) was found inactive alone at the tested doses. It is noteworthy that the antifibrotic properties of the various statin family members do not seem to be related to their lipid lowering capacity. For example, Rosuvastatin, which is considered the most potent statin for HMG_CoA reductase Inhibition (IC₅₀=5.4 nM; (McKenney, 2003) revealed weak antifibrotic properties.

In order to evaluate if a combination of statin with NTZ or TZ could reduce fibrosis in a synergistic manner, combination matrix experiments were performed in TGF β -induced HSCs. Briefly, NTZ or TZ and statin solutions were serially diluted in a checkerboard format generating a 36 combinations matrix covering a large panel of statin/NTZ or statin/TZ ratios. Synergy was first determined by calculating Excess Over Bliss scores. In order to rank the different statins based on their synergism, the sum of the EOB scores obtained for each statin was also calculated. These experiments revealed that NTZ could synergize with all statins, but not with the same potency, to reduce α -SMA production in activated HSCs.

The best synergy was obtained with NTZ in combination with Pitavastatin (total EOB score of 337), followed by Simvastatin (total EOB score of 255), Fluvastatin (total EOB score of 141),

Lovastatin (total EOB score of 91), Pravastatin (total EOB score of 88), and Atorvastatin (total EOB score of 73) (Fig. 4B, 5B, 6B, 7B and 8B). Positive EOB score were obtained only for a few NTZ/ROSU ratios (data not shown) indicating a synergy, but weaker, comparatively to the other NTZ/statin combinations. To validate the synergism, the experimental values corresponding to the EOB score for each NTZ/statin combination were plotted in a bar graph (Fig. 4C, 5C, 6C, 7C, and 8C).

These graphs illustrate that the combination of NTZ with Pitavastatin, Simvastatin, Fluvastatin, Lovastatin, Atorvastatin and Pravastatin show a superior antifibrotic effect that is statistically significant compared to the highest single agent (NTZ or statin). The most impressive examples are represented with Pitavastatin, Simvastatin, or Fluvastatin in which the single agents provide a weak antifibrotic activity (~10 to 20% inhibition) at suboptimal doses, however, when combined with NTZ, reach an inhibition of α -SMA in the order of 60 to 70%. Tizoxanide, the active metabolite of NTZ, was also evaluated in combination with the statins that revealed the best synergism with NTZ, namely Pitavastatin, Simvastatin and Fluvastatin. As observed with NTZ, the TZ metabolite also synergized with these 3 statins (an example with Fluvastatin is shown in Fig.9).

In addition to their antifibrotic properties, it was found that a combination of NTZ at 30 mg/kg/day with Simvastatin at 10 mg/kg/day synergized to prevent the occurrence of altered levels of circulating bile acids in a model of CCl₄-induced liver injury (Fig.10). In conclusion, the applicant has discovered unexpected anticholestatic and antifibrotic activities for a combination of a compound of Formula (I) statins. These results suggest that a combination of a compound of Formula (I) with a statin can be synergistic and can provide therapeutic benefits in multiple types of cholestatic and fibrotic diseases.
