

COVALENT ATTACHMENT OF MACROMOLECULES
ON SUBSTRATE SURFACES

5

ABSTRACT

Uncrosslinked polystyrene surfaces are
10 derivatized under Friedel-Crafts conditions in a
tetramethylenesulfone solvent using a substituted
N-hydroymethyl acetamide derivatizing agent. The
substituent is subject to nucleophilic substitution to
allow for the binding of a wide variety of molecules,
15 particularly specific binding pair members, to the
surface. Clarity is maintained for monitoring
observation of events on the surface through the
polystyrene.
