

DESCRIPTION

TITLE OF INVENTION: REINFORCING BAR BINDING DEVICE

5 TECHNICAL FIELD

[0001] The present disclosure relates to a reinforcing bar binding device.

BACKGROUND ART

[0002] In related art, various techniques have been proposed for automating reinforcing bar
10 binding during building construction. For example, Patent Literature 1 describes a self-
propelled reinforcing bar binding robot that has a function of moving in a longitudinal direction
(first direction) using a pair of parallel reinforcing bars as traveling rails, and a function of
moving in a lateral direction (second direction) between the parallel reinforcing bars, and if the
robot detects a reinforcing bar extending in the lateral direction while moving in the longitudinal
15 direction, the robot stops moving and binds the reinforcing bars at a place where the reinforcing
bar extending in the longitudinal direction and the reinforcing bar extending in the lateral
direction intersect with each other.

CITATION LIST

20 PATENT LITERATURE

[0003] Patent Literature 1: JP2019-039174A

SUMMARY OF INVENTION

TECHNICAL PROBLEM

25 [0004] However, in the related art, there was a problem that the movement of the robot in
the lateral direction cannot be performed with precision.

[0005] The present disclosure has been made in consideration of the above circumstances,
and an object thereof is to provide a reinforcing bar binding device that can perform precise
movement in a second direction.

30 SOLUTION TO PROBLEM

[0006] A reinforcing bar binding device according to one aspect of the present disclosure
includes a binding mechanism configured to bind a position where a reinforcing bar extending
in a first direction and a reinforcing bar extending in a second direction intersect with each other,

a main body to which the binding mechanism is mounted, a leg configured to travel along the reinforcing bar extending in the first direction, a first drive unit configured to move the leg away from the reinforcing bar, a second drive unit configured to move the leg in the second direction intersecting the first direction, and a control unit configured to control the first drive unit and the second drive unit, in which the control unit first controls the first drive unit to move the leg away from the reinforcing bar, and then controls the second drive unit to move the leg in the second direction.

[0007] According to this aspect, by moving the leg in the second direction, the movement in the second direction can be performed with precision.

ADVANTAGEOUS EFFECTS OF INVENTION

[0008] According to the present disclosure, movement in the second direction can be performed with precision.

5

DESCRIPTION OF EMBODIMENTS

[0010] A reinforcing bar binding device of the present embodiment will be described with reference to the drawings. Note that in the following description, for the sake of convenience in understanding the specification, an advancing direction of the reinforcing bar binding device is defined as an X-axis direction, a width direction of the reinforcing bar binding device is defined as a Y-axis direction, and a height direction of the reinforcing bar binding device is defined as a Z-axis direction.

[0011] The reinforcing bar binding device of the present embodiment is a self-propelled robot that, for example, in building construction, automatically performs binding processing at a binding position where a reinforcing bar extending in the X-axis direction (hereinafter also referred to as a "longitudinal bar") and a reinforcing bar extending in the Y-axis direction (hereinafter also referred to as a "lateral bar") intersect. When the reinforcing bar binding device is operating, the reinforcing bar binding device travels along the X-axis direction following the longitudinal bar, and upon detecting a lateral bar, the reinforcing bar binding device stops the traveling and performs binding processing on the binding position. The reinforcing bar binding device resumes the traveling once the binding processing is completed. Thereafter, the reinforcing bar binding device repeats the traveling, stopping, and binding, while performing the binding processing on a plurality of binding positions. When the reinforcing bar binding device reaches an end of the longitudinal bar in the X-axis direction, the reinforcing bar binding device performs lateral movement processing of moving to a longitudinal bar adjacent to the longitudinal bar on which the reinforcing bar binding device is traveling in the Y-axis direction. Then, when the lateral movement processing is completed, the reinforcing bar binding device resumes traveling in the X-axis direction following the longitudinal bar, and performs the binding processing on the binding position on the adjacent longitudinal bar in the Y-axis direction.

30

[0012] As shown in FIGS. 1 and 2, the reinforcing bar binding device 10 of the present embodiment includes a main body 11, a leg structure 12 connected to the main body 11, and a support frame 13 connected to the main body 11. The support frame 13 is an example of a

support portion.

[0013] The leg structure 12 includes a first unit 12A and a second unit 12B that are provided in a pair at a front side and a rear side of the main body 11. The support frame 13 is disposed, for example, between the first unit 12A and the second unit 12B. The support frame 13 may be positioned in front of the first unit 12A (a front side in the advancing direction of the reinforcing bar binding device 10) or behind the second unit 12B (a rear side in the advancing direction of the reinforcing bar binding device 10). The first unit 12A and the second unit 12B each include two legs 15. One leg 15 of the first unit 12A and one leg 15 of the second unit 12B serve an example of a third leg, and are provided on one side of the main body 11 in the Y-axis direction. The other leg 15 of the first unit 12A and the other leg 15 of the second unit 12B serve an example of a fourth leg, and are provided on the other side of the main body 11 in the Y-axis direction. The two legs 15 of the first unit 12A serve an example of a first leg, and are provided on one side of the main body 11 in the X-axis direction (a front side in the advancing direction of the reinforcing bar binding device 10). The two legs 15 of the second unit 12B serve an example of a second leg, and are provided on the other side of the main body 11 in the X-axis direction (a rear side in the advancing direction of the reinforcing bar binding device 10). The number of the legs 15 of each of the first unit 12A and the second unit 12B may be one, or three or more. Each leg 15 can be extended or retracted individually, allowing a height of the main body 11 to be adjusted through extension or retraction of each leg 15. The support frame 13 has a frame-like shape extending along the Y-axis direction, and includes two first frame portions 13A extending in the Z-axis direction from a lower surface of the main body 11, and a second frame portion 13B extending in the Y-axis direction and connecting lower ends of the two first frame portions 13A. A dimension of the second frame portion 13B in the Y-axis direction is configured to be approximately three times a distance between adjacent longitudinal bars in the Y-axis direction, for example. The dimension of the second frame portion 13B in the Y-axis direction may also be configured to be approximately the same as the distance between adjacent longitudinal bars in the Y-axis direction, for example. In this way, when the height of the main body 11 decreases due to the extension and retraction of each leg 15, the support frame 13 is placed such that the second frame portion 13B of the support frame 13 straddles two adjacent longitudinal bars X1 and X3, or longitudinal bars X1 and X2, in the Y-axis direction. That is, the second frame portion 13B of the support frame 13 is placed to straddle two longitudinal bars, X1 and X3 or X1 and X2, where the longitudinal bar X1 is positioned at a center in the Y-axis direction of the main body 11, and the two longitudinal bars X2 and X3 are positioned on

both sides of the longitudinal bar X1 in the Y-axis direction.

[0014] A sensor 16 is mounted on both sides of the main body 11 in the X-axis direction. The sensor 16 is an example of a second detection unit. Note that in the example shown in FIGS. 1 and 2, only the sensor 16 mounted on a front surface of the main body 11 is shown. A detection range of the sensor 16 covers an area below the main body 11, for example, and the detection range includes at least the longitudinal bar X1 positioned in the center of the main body 11 in the Y-axis direction. The sensor 16, for example, has a function of measuring a distance to an object, and detects that the object is the longitudinal bar X1 on condition that a measured value of the distance to the object matches a distance preset as a distance to the longitudinal bar X1.

10 The two sensors 16 detect two points on the longitudinal bar X1 that are separated in the X-axis direction, and a direction of a straight line connecting the two points detected by these sensors 16 extends is identified as a lengthwise direction of the longitudinal bar X1. Then, the reinforcing bar binding device 10 independently controls a rotation speed of each wheel 17 on both sides in the Y-axis direction to align with the specified lengthwise direction of the longitudinal bar X1. The reinforcing bar binding device 10 moves following the longitudinal bar X1 while controlling a movement direction of the reinforcing bar binding device 10 to align with the lengthwise direction of the longitudinal bar X1 specified as described above.

[0015] A sensor 18 is mounted on both sides of the main body 11 in the Y-axis direction. The sensor 18 is an example of a first detection unit. Note that in the example shown in FIGS. 1 and 2, only the sensor 18 mounted on one side surface of the main body 11 in the Y-axis direction is shown. A detection range of the sensor 18 is, for example, below the main body 11, and the detection range includes at least a lateral bar Y1 (see FIG. 9 and the like) that crosses the main body 11 in the Y-axis direction when the reinforcing bar binding device 10 reaches a vicinity of a binding position. The sensor 18, for example, has a function of measuring a distance to an object, and detects that the object is the lateral bar Y1 on condition that a measured value of the distance to the object matches a distance preset as a distance to the lateral bar Y1. The two sensors 18 detect two points of the lateral bar Y1 separated in the Y-axis direction, and when a lateral bar is detected by these sensors 18, a direction in which a straight line connecting the two detected points extends is specified as a lengthwise direction of the lateral bar. The reinforcing bar binding device 10 then calculates a position where the lengthwise direction of the longitudinal bar specified by the sensors 16 intersects with the lengthwise direction of the lateral bar specified by the sensors 18 as the binding position where the longitudinal bar and the lateral bar intersect with each other. When the reinforcing bar binding device 10 moves

toward the calculated binding position, the reinforcing bar binding device 10 individually controls rotation speeds of the wheels 17 on both sides in the Y-axis direction, and controls the movement direction of the reinforcing bar binding device 10 so that the position of the calculated binding position coincides in the Y-axis direction with a position of a binding portion 73 of the binding mechanism 70 described later.

[0016] Next, a configuration of each unit forming the leg structure 12 will be described. Note that the first unit 12A and the second unit 12B have a common configuration. Therefore, the following description will be made using the first unit 12A as an example.

[0017] As shown in FIG. 3, the first unit 12A includes, for example, a connecting portion 30 that is connected to the main body 11 and extends long in one direction, and legs 15 provided at a first end and a second end of the connecting portion 30 in the lengthwise direction. The connecting portion 30 has, for example, a substantially L-shaped cross section. The connecting portion 30 includes, for example, a bottom plate 31 and a side plate 32 protruding from the bottom plate 31 in the Z-axis direction. The bottom plate 31 includes, for example, a first bottom plate 31A positioned on one side of the connecting portion 30 in the lengthwise direction, and a second bottom plate 31B positioned on the other side of the connecting portion 30 in the lengthwise direction. Between the first bottom plate 31A and the second bottom plate 31B, for example, a gap is formed in the lengthwise direction of the connecting portion 30. The side plate 32 extends, for example, over the entire connecting portion 30 in the lengthwise direction. That is, the connecting portion 30 may have a configuration in which the bottom plate 31 is cut out in a central portion in the lengthwise direction. A lateral movement roller 33 is provided at a central portion in the lengthwise direction of the side plate 32 of the connecting portion 30. The lateral movement roller 33 is an example of a drive gear, and forms a second drive unit. The lateral movement roller 33 meshes with, for example, a drive rack 11A provided on the main body 11. The drive rack 11A is an example of a meshing portion, and forms the second drive unit. The drive rack 11A includes, for example, a plurality of teeth that mesh with external teeth of the lateral movement roller 33 and are aligned linearly in the Y-axis direction. The lateral movement roller 33 may be provided on the main body 11, and the drive rack 11A may be provided on the connecting portion 30. When the lateral movement roller 33 rotates based on a driving force from a motor that forms the second drive unit, the lateral movement roller 33 moves relative to the drive rack 11A along the lengthwise direction of the drive rack 11A, and the main body 11 and the first unit 12A may move relative to each other in the Y-axis direction. Further, for example, one leg 15 is connected to each of the first bottom plate 31A and the

second bottom plate 31B of the connecting portion 30.

[0018] The leg 15 includes a base 40 (see FIG. 7 and the like) connected to the first bottom plate 31A or the second bottom plate 31B of the connecting portion 30. A displacement mechanism 41 is connected to the base 40. A displacement mechanism 41 is configured to
5 displace, with the first end connected to the base 40 as a fixed end and the second end opposite to the first end as a free end. The displacement mechanism 41 includes a link mechanism 41A that connects the wheel 17 and the main body 11. The link mechanism 41A is an example of a junction portion, and is configured to extend and retract. The link mechanism 41A, for example, is connected with a plurality of links extending long in one direction in a rotatable manner, and
10 the plurality of links include a first link 42 positioned at the first end and a second link 43 positioned at the second end. The first link 42 is connected to the second link 43 in a rotatable manner. The displacement mechanism 41 is provided on each leg 15 of the first unit 12A and the second unit 12B, and is configured to be independently controlled. In other words, the displacement mechanism 41 of the first leg and the displacement mechanism 41 of the second
15 leg are configured to change the distance between the main body 11 and the longitudinal bar to different distances. The displacement mechanism 41 of the third leg and the displacement mechanism 41 of the fourth leg are configured to change the distance between the main body 11 and the longitudinal bar to different distances.

[0019] The first link 42 includes a pair of link members 42A, 42B connected, in a rotatable
20 manner, to both ends in an axial direction of a rotating shaft 44 provided at a tip of the base 40, and a restricting link mechanism 45 connected, in a rotatable manner, to an intermediate position between the pair of link members 42A, 42B in the axial direction of the rotating shaft 44 and restricting a displacement direction of the displacement mechanism 41. The pair of link members 42A, 42B have a shape that extends long in one direction, and the first end is
25 connected, in a rotatable manner, to the rotating shaft 44, and the second end is connected, in a rotatable manner, to a second rotating shaft 49 provided at the first end of the second link 43. The restricting link mechanism 45 is constructed by connecting a plurality of restricting links 47 extending long in one direction in a rotatable manner, and includes a first restricting link 47A connected to the tip of the base 40, and a second restricting link 47B connecting the first
30 restricting link 47A and the second link 43. A first end of the first restricting link 47A is connected, in a rotatable manner, to the rotating shaft 44 provided at the tip of the base 40, and a second end of the first restricting link 47A is connected, in a rotatable manner, to a first end of the second restricting link 47B via a rotating shaft 48. The first end of the second restricting

link 47B is connected, in a rotatable manner, to the second end of the first restricting link 47A via the rotating shaft 48, and a second end of the second restricting link 47B is connected, in a rotatable manner, to a first rotating shaft 46 provided at the first end of the second link 43. The rotating shaft 48 connecting the first restricting link 47A and the second restricting link 47B functions as protrusions that protrude from a connecting position between the first restricting link 47A and the second restricting link 47B to both sides in the axial direction of the rotating shaft 48. An upward biasing force is applied to these protrusions by coil springs 50 provided on the first link 42. The coil springs 50 are an example of a biasing member, and are provided in a pair on both sides of the first link 42 in the axial direction of the rotating shaft 48 with the restricting link mechanism 45 in between.

[0020] The second link 43 supports both ends of the first rotating shaft 46 and the second rotating shaft 49 in the axial direction. The first rotating shaft 46 and the second rotating shaft 49 are disposed side by side in the lengthwise direction of the second link 43. The second end of the second restricting link 47B of the restricting link mechanism 45 is connected, in a rotatable manner, to a central portion of the first rotating shaft 46 in the axial direction. The second ends of the pair of link members 42A, 42B of the first link 42 are connected, in a rotatable manner, to both ends of the second rotating shaft 49 in the axial direction, respectively. A motor 51 for driving the second rotating shaft 49 to rotate is provided at a central portion of the second rotating shaft 49 in the axial direction. The motor 51 is an example of a first drive unit. The motor 51 is provided for each of the pair of link members 42A, 42B.

[0021] The second link 43 includes a generally U-shaped bearing, and the bearing supports the wheel 17 in a rotatable manner. The wheel 17 includes disk-shaped flanges 17A on both sides in the width direction to prevent falling off from the longitudinal bars X2, X3. A motor 52 for driving the wheel 17 to rotate is provided on an outer surface of the bearing. That is, the reinforcing bar binding device 10 is provided with the motors 52 for each of the four wheels 17, so that rotation of each wheel 17 can be controlled individually. The motor 52 may be built in each wheel 17.

[0022] As shown in FIG. 8, when the second rotating shaft 49 is driven by the motor 51 to rotate, the second link 43 rotates relative to the first link 42 around the second rotating shaft 49 in conjunction with the rotation of the second rotating shaft 49. In this example, the second link 43 rotates in the clockwise direction shown in FIG. 8 around the second rotating shaft 49, and the second link 43 rotates relative to the first link 42 so that an angle between the first link 42 and the second link 43 becomes larger. In this case, since the displacement mechanism 41 is

configured to displace, with the first end connected to the base 40 as a fixed end and the second end opposite to the first end as a free end, the second rotating shaft 49 moves in the X-axis direction toward the base 40. Here, the displacement direction of the wheel 17 provided at the tip of the displacement mechanism 41 is restricted by the restricting link mechanism 45 of the displacement mechanism 41. Therefore, while being driven by the motor 51, the wheel 17 provided at the tip of the displacement mechanism 41 rises or falls in an upper-lower direction.

[0023] As shown in FIGS. 9 and 10, the main body 11 includes a penetration 60 that penetrates the main body 11 in the Z-axis direction. The penetration 60 opens on an upper surface of the main body 11, and the binding mechanism 70 is inserted from above.

[0024] The binding mechanism 70 has a columnar shape and includes a holding portion 71, a lifting portion 72 as an example of a lifting drive unit, and the binding portion 73. The holding portion 71 is provided at a central portion of the binding mechanism 70 in the lengthwise direction. The holding portion 71 holds a roll of wound metal wire. When the reinforcing bar binding device 10 moves to the binding position, the binding portion 73 is lowered by the lifting portion 72 to approach the binding position and performs a binding work using the wire, and then rises to move away from the binding position after the binding work is completed. The binding portion 73 has a configuration in which two arms 73A and 73B cross each other in an approximately V-shape, and with a direction in which the two arms 73A and 73B face each other aligned in a direction that crosses the binding position diagonally, the wire unwound from the holding portion 71 is wound between one arm 73A and the other arm 73B to perform binding processing on the binding position using the wire. More specifically, the binding portion 73 performs the binding processing on the binding position using the wire by performing operations such as winding the wire around the binding position, winding the wire wound around the binding position in close contact with the binding position, and twisting the wire wound around the binding position.

[0025] The binding mechanism 70 includes a disk-shaped engagement portion 74. A shape of the engagement portion 74 in a plan view is larger than an opening shape of the penetration 60. Therefore, when the binding mechanism 70 is inserted into the penetration 60, the engagement portion 74 engages with an opening edge of the penetration 60 in the Z-axis direction, thereby positioning the binding mechanism 70. In this case, the binding mechanism 70 is provided with the binding portion 73 on one side in the lengthwise direction with the engagement portion 74 as a reference (in this example, a lower side).

[0026] The binding mechanism 70 is provided with the lifting portion 72 that raises and

lowers the binding portion 73 in the Z-axis direction. Then, when the reinforcing bar binding device 10 reaches the binding position, in addition to the extension and retraction of each leg 15 of the main body 11, the lifting portion 72 raises and lowers the binding portion 73 in the Z-axis direction, thereby precisely lowering the binding portion 73 to the binding position and accurately performing the binding processing on the binding position using the wire.

[0027] As shown in FIGS. 11A and 11B, when the binding mechanism 70 is inserted into the main body 11, the binding portion 73 of the binding mechanism 70 protrudes downward from the lower surface of the main body 11. The reinforcing bar binding device 10 then travels following the longitudinal bar X1. In this case, the binding portion 73 of the binding mechanism 70 is disposed above and away from the longitudinal bar X1. As shown in FIG. 11C, the two arms 73A and 73B of the binding portion 73 face each other in a direction that intersects diagonally with the lengthwise direction of the longitudinal bar X1.

[0028] Then, as shown in FIGS. 12A and 12B, the reinforcing bar binding device 10 travels following the longitudinal bar X1, and when the reinforcing bar binding device 10 reaches a position opposite to the lateral bar in the Z-axis direction, the binding portion 73 of the binding mechanism 70 is lowered to a position where a distance from the longitudinal bar or the lateral bar becomes a predetermined distance as each leg 15 of the main body 11 extends or retracts, and the binding portion 73 of the binding mechanism 70 is aligned with the binding position in the Z-axis direction. In this case, as shown in FIG. 12C, the two arms 73A and 73B of the binding portion 73 face each other in a direction that crosses the binding position diagonally. The binding portion 73 then winds the wire around from one arm 73A to the other arm 73B, thereby performing the binding processing on the binding position using the wire.

[0029] The binding mechanism 70 is configured to rotate in a circumferential direction about a rotation axis passing through a center of the opening of the penetration 60 when inserted into the penetration 60. In this case, the binding mechanism 70 may be rotated manually, or may be rotated based on a driving force from a motor, which is an example of a rotation drive unit. When the binding mechanism 70 rotates in the circumferential direction about the rotation axis, an orientation of the two arms 73A and 73B of the binding portion 73 is changed. Therefore, the binding mechanism 70 can use the wire to perform the binding processing on the binding position not only when the longitudinal bar and the lateral bar intersect with each other at a right angle, but also when the longitudinal bar and the lateral bar intersect with each other diagonally.

[0030] Next, a control configuration of the reinforcing bar binding device 10 of the present

embodiment will be described.

[0031] As shown in FIG. 13, the control device 100 of the reinforcing bar binding device 10 is implemented by, for example, a hardware processor such as a central processing unit (CPU) executing a program (software). Furthermore, some or all of these components may be implemented by hardware (including circuitry) such as a large scale integration (LSI), an application specific integrated circuit (ASIC), a field-programmable gate array (FPGA), or a graphics processing unit (GPU), or may be implemented by a combination of software and hardware. The program may be stored in advance in a computer-readable recording device such as an HDD or a flash memory of the control device 100, or may be stored in a removable computer-readable recording medium such as a DVD or a CD-ROM, and installed in the HDD or the flash memory of the control device 100 by inserting the computer-readable recording medium into a drive device.

[0032] The control device 100 includes, for example, a position information obtaining unit 110, a posture information obtaining unit 160, a following control unit 120, a stop control unit 130, a lateral movement control unit 140, a lifting control unit 150, a leveling control unit 170, and a motor control unit 180.

[0033] The position information obtaining unit 110 obtains information related to the position of the reinforcing bar binding device 10 based on information obtained from a camera group 200. The camera group 200 includes, for example, sensors 16 provided on both sides of the reinforcing bar binding device 10 in the X-axis direction, and sensors 18 provided on both sides of the reinforcing bar binding device 10 in the Y-axis direction. The information related to the position of the reinforcing bar binding device 10 includes, for example, information related to the lengthwise direction of the longitudinal bar and information related to the lengthwise direction of the lateral bar specified by the camera group 200.

[0034] The following control unit 120 controls traveling of the reinforcing bar binding device 10 so as to follow the longitudinal bar, based on the information related to the position of the reinforcing bar binding device 10 obtained by the position information obtaining unit 110. The following control unit 120 controls the traveling of the reinforcing bar binding device 10 so that a movement direction of the reinforcing bar binding device 10 aligns with the lengthwise direction of the longitudinal bar based on, for example, the information related to the lengthwise direction of the longitudinal bar obtained by the position information obtaining unit 110. The following control unit 120 determines a control amount for a motor group 230 by the motor control unit 180 so as to align the movement direction of the reinforcing bar binding device 10

with the lengthwise direction of the longitudinal bar, for example. In this case, the motor group 230 includes, for example, the motor 52 that controls the rotation of each wheel 17. The following control unit 120 measures a load of the motor 52 that drives the reinforcing bar binding device 10 to move along the lengthwise direction of the longitudinal bar.

5 [0035] When the reinforcing bar binding device 10 moves forward, the following control unit 120 drives the motor 51 to control the extension and retraction of each leg 15, and for the legs 15 positioned at a front side of the reinforcing bar binding device 10 among the plurality of legs 15 forming the leg structure 12, a connection point between the first link 42 positioned at the first end and the second link 43 positioned at the second end is disposed at the front side
10 of the reinforcing bar binding device 10 in the displacement mechanism 41. The following control unit 120 then determines whether the reinforcing bar binding device 10 collides with an obstacle based on a change in the load of the motor that moves the reinforcing bar binding device 10 forward. The following control unit 120 is an example of a first determination unit.

[0036] The stop control unit 130 controls the traveling of the reinforcing bar binding device
15 10 so as to stop reinforcing bar binding device 10 at the binding position where the longitudinal bar and the lateral bar intersect with each other, based on the information related to the position of the reinforcing bar binding device 10 obtained by the position information obtaining unit 110. The stop control unit 130, for example, specifies the position where the lengthwise direction of the longitudinal bar and the lengthwise direction of the lateral bar specified by the camera group
20 200 intersect with each other as the binding position where the longitudinal bar and the lateral bar intersect with each other, and stops the movement of the reinforcing bar binding device 10 at the position of the specified binding position. The stop control unit 130 determines the control amount for the motor group 230 by the motor control unit 180 so as to stop the movement of the reinforcing bar binding device 10 at the binding position where the longitudinal bar and the
25 lateral bar intersect with each other, for example. In this case, the motor group 230 includes, for example, the motor 52 that controls the rotation of each wheel 17.

[0037] The lateral movement control unit 140 is an example of a control unit, and controls the lateral movement of the reinforcing bar binding device 10 based on the information related to the position of the reinforcing bar binding device 10 obtained by the position information
30 obtaining unit 110, for example. The lateral movement control unit 140 is an example of a movement amount calculation unit, and calculates a movement amount of the main body 11 in the lateral direction based on the information related to the position of the reinforcing bar binding device 10 obtained by the position information obtaining unit 110, for example. For

example, when it is detected that the reinforcing bar binding device 10 reaches an end of the longitudinal bar in the lengthwise direction based on the information related to the position of the reinforcing bar binding device 10 obtained by the position information obtaining unit 110, the lateral movement control unit 140 executes lateral movement processing of the reinforcing bar binding device 10 so as to change the longitudinal bar on which each wheel 17 of the reinforcing bar binding device 10 is placed to an adjacent longitudinal bar in the Y-axis direction. The lateral movement control unit 140 determines the control amount for the motor group 230 by the motor control unit 180 in each step of the lateral movement processing, for example. In this case, the motor group 230 includes, for example, the motor 52 that controls the rotation of each wheel 17, the motor 51 that controls the extension and retraction of each leg 15, and the motor that causes the main body 11 and the leg structure 12 to perform lateral movement.

[0038] The lateral movement control unit 140 measures a load on the motor that drives the lateral movement roller 33 when the reinforcing bar binding device 10 moves to the adjacent longitudinal bar in the Y-axis direction, and determines whether the lateral movement processing of the reinforcing bar binding device 10 is normally performed based on a change in the load of the measured motor. The lateral movement control unit 140 is an example of a second determination unit. For example, when the load of the measured motor is equal to or greater than a predetermined threshold, the lateral movement control unit 140 determines that the lateral movement processing of the reinforcing bar binding device 10 is not normally performed, such as when the wheel 17 at the tip of the leg 15 collides with the longitudinal bar X2 or X3. For example, when it is determined that the lateral movement processing of the reinforcing bar binding device 10 is not normally performed, the lateral movement control unit 140 controls the driving of the motor 51 that extends and retracts each leg 15 so as to move the wheel 17 away from the longitudinal bars X2, X3.

[0039] The lifting control unit 150 controls lifting of the binding portion 73 of the binding mechanism 70 based on the information related to the position of the reinforcing bar binding device 10 obtained by the position information obtaining unit 110. The lifting control unit 150 controls the lifting of the binding mechanism 70 so as to lower the binding portion 73 of the binding mechanism 70, for example, when the reinforcing bar binding device 10 reaches the binding position where the longitudinal bar and the lateral bar intersect with each other. The lifting control unit 150 determines the control amount for the motor group 230 by the motor control unit 180 so as to lower the binding portion 73 of the binding mechanism 70, for example. In this case, the motor group 230 includes the motor that lifts the binding portion 73 of the

binding mechanism 70.

[0040] The posture information obtaining unit 160 obtains information related to a posture of the reinforcing bar binding device 10 based on information obtained from a sensor group 210 and the motor group 230. The posture information obtaining unit 160 obtains, for example, information related to the motor load of the motor that controls the extension and retraction of each leg 15 as the information related to the posture of the reinforcing bar binding device 10, and determines a leveling level of the main body 11 based on the obtained information related to the motor load. In this case, the sensor group 210 includes, for example, a sensor that measures the motor load of the motor that controls the extension and retraction of each leg 15 and an inclination detection sensor such as a gyro sensor that detects an inclination of the posture of the reinforcing bar binding device 10. The motor group 230 includes, for example, the motor 51 that controls the extension and retraction of each leg 15.

[0041] The leveling control unit 170 is an example of the control unit, and controls the posture of the reinforcing bar binding device 10 so as to maintain a level posture, for example, based on the information related to the posture of the reinforcing bar binding device 10 obtained by the posture information obtaining unit 160. The leveling control unit 170, for example, measures the motor load of the motor 51 that controls the extension and retraction of each leg 15, and determines the control amount for the motor group 230 by the motor control unit 180 so that a total value of the motor loads of the measured motors 51 is minimized. In this case, the motor group 230 includes the motor 51 that controls the extension and retraction of each leg 15.

[0042] Next, the binding processing executed by the reinforcing bar binding device 10 of the present embodiment will be described. FIG. 14 is a flowchart showing an example of the binding processing. The flowchart shown in FIG. 14 is executed, for example, when an operation of the reinforcing bar binding device 10 is started.

[0043] As shown in FIG. 14, the control device 100 first measures the motor load of the motor 51 that extends and retracts each leg 15 of the leg structure 12 (step S100).

[0044] Next, the control device 100 sets a drive amount of the motor 51 that extends and retracts each leg 15 so that the total value of the motor load of each motor measured in the previous step S100 is minimized, and controls the posture of the reinforcing bar binding device 10 to maintain a level posture (step S200).

[0045] Next, the control device 100 specifies the lengthwise direction of the longitudinal bar X1 using the sensors 16 provided on both sides of the main body 11 in the X-axis direction, and

sets the drive amount of the motor 52 that rotates each wheel 17 based on the specified lengthwise direction of the longitudinal bar X1, and causes the reinforcing bar binding device 10 to travel in a manner of following the longitudinal bar X1 (step S300).

[0046] Next, the control device 100 determines whether a lateral bar is detected by the sensors 18 provided on both sides of the main body 11 in the Y-axis direction (step S400).

[0047] If it is determined in the previous step S400 that no lateral bar is detected (step S400 = NO), the control device 100 determines whether or not a condition for lateral movement is satisfied (step S500). The condition for lateral movement is satisfied when, for example, the reinforcing bar binding device 10 reaches an end of the longitudinal bar X1 in the X-axis direction, or an obstacle is detected ahead in the advancing direction of the reinforcing bar binding device 10.

[0048] If it is determined in the previous step S500 that the condition for lateral movement is not satisfied (step S500 = NO), the control device 100 returns the processing to step S100. On the other hand, if it is determined in the previous step S500 that the condition for lateral movement is satisfied (step S500 = YES), the control device 100 executes the lateral movement processing of the reinforcing bar binding device 10 (step S600).

[0049] As shown in FIG. 15, in the performing of the lateral movement processing of the reinforcing bar binding device 10, the control device 100 first drives the lateral movement roller 33 in a forward direction, which is a first drive direction, and moves the main body 11 in the Y-axis direction relative to the leg structure 12 while supporting the leg structure 12 by bringing each leg 15 forming the leg structure 12 into contact with the longitudinal bar X1 (step S601).

[0050] Next, the control device 100 determines whether the drive amount of the lateral movement roller 33 that is driven in the forward direction in the previous step S601 reaches a first threshold (step S602).

[0051] If it is determined that the drive amount of the lateral movement roller 33 does not reach the first threshold (step S602 = NO), the control device 100 returns the processing to step S603. On the other hand, if it is determined that the drive amount of the lateral movement roller 33 reaches the first threshold (step S602 = YES), the control device 100 drives the motor 51 that extends and retracts each leg 15 forming the leg structure 12, thereby retracting each leg 15 and lowering the height of the main body 11 (step S603).

[0052] Next, the control device 100 determines whether each leg 15 is away from the longitudinal bars X2, X3 (whether the support frame 13 is in contact with the longitudinal bars X1, X3) based on the drive amount of the motor 51 that extends and retracts each leg 15 forming

the leg structure 12 (step S604).

[0053] When it is determined that not each leg 15 is away from the longitudinal bars X2, X3 (step S604 = NO), the control device 100 returns the processing to step S603. On the other hand, if it is determined that each leg 15 is away from the longitudinal bars X2, X3 (step S604 = YES),
 5 the control device 100 drives the lateral movement roller 33 in a reverse direction, which is a second drive direction, and moves the leg structure 12 in the Y-axis direction relative to the main body 11 while supporting the main body 11 by bringing the support frame 13 into contact with the longitudinal bars X1, X3 (step S605).

[0054] Next, the control device 100 determines whether the drive amount of the lateral
 10 movement roller 33 that is driven in the reverse direction in the previous step S605 reaches a second threshold (step S606).

[0055] If it is determined that the drive amount of the lateral movement roller 33 does not reach the second threshold (step S606 = NO), the control device 100 returns the processing to step S605. On the other hand, if it is determined that the drive amount of the lateral movement
 15 roller 33 reaches the second threshold (step S606 = YES), the control device 100 drives the motor 51 that extends and retracts each leg 15 forming the leg structure 12, thereby extending each leg 15 (step S607).

[0056] Next, the control device 100 determines whether the support frame 13 connected to the main body 11 is away from the longitudinal bars X1, X3 (whether each leg 15 is in contact
 20 with the longitudinal bars X1, X4) based on the drive amount of the motor 51 that extends and retracts each leg 15 forming the leg structure 12 (step S608).

[0057] If it is determined that not each leg 15 is in contact with the longitudinal bars X1, X4 (step S608 = NO), the control device 100 returns the processing to step S607. On the other hand, if it is determined that each leg 15 is in contact with the longitudinal bars X1, X4 (step S608 =
 25 YES), the control device 100 drives the lateral movement roller 33 in the forward direction, and moves the main body 11 in the Y-axis direction relative to the leg structure 12 while supporting the leg structure 12 by bringing each leg 15 forming the leg structure 12 into contact with the longitudinal bars X1, X4 (step S609).

[0058] Next, the control device 100 determines whether the drive amount of the lateral
 30 movement roller 33 that is driven in the forward direction in the previous step S609 reaches a third threshold (step S610).

[0059] If it is determined that the drive amount of the lateral movement roller 33 does not reach the third threshold (step S610 = NO), the control device 100 returns the processing to step

S609. On the other hand, if it is determined that the drive amount of the lateral movement roller 33 reaches the third threshold (step S610 = YES), the control device 100 ends the lateral movement processing shown in FIG. 15.

[0060] With reference to FIG. 14 again, when the control device 100 executes the lateral movement processing of the reinforcing bar binding device 10 in the previous step S600, the control device 100 returns the processing to step S100.

[0061] If it is determined that the lateral bar Y1 is detected in the previous step S400 (step S400 = YES), the control device 100 stops driving the motor 52 that rotates each wheel 17 and stops the movement of the reinforcing bar binding device 10 (step S700).

[0062] Next, the control device 100 controls the lifting portion 72 to lift the binding portion 73 of the binding mechanism 70 relative to the main body 11, and adjusts the position of the binding portion 73 of the binding mechanism 70 in the Z-axis direction relative to the binding position where the longitudinal bar X3 and the lateral bar Y1 intersect with each other (step S800).

[0063] Next, the control device 100 controls the operation of the binding mechanism 70, the position of which in the Z-axis direction is controlled, to bind at the binding position (step S900).

[0064] Next, the control device 100 determines whether the operation of the reinforcing bar binding device 10 is stopped (step S1000). If it is determined that the operation of the reinforcing bar binding device 10 is not stopped (step S1000 = NO), the control device 100 returns the processing to step S100 and repeats the processing of steps S100 to S900 until the operation of the reinforcing bar binding device 10 is stopped. On the other hand, if it is determined that the operation of the reinforcing bar binding device 10 is stopped (step S1000 = YES), the control device 100 ends the flowchart shown in FIG. 14.

[0065] Next, an operation of the reinforcing bar binding device 10 of the present embodiment when performing the lateral movement processing will be described.

[0066] In the example shown in FIGS. 16A and 16B, in the reinforcing bar binding device 10, the wheels 17 of each leg 15 forming the leg structure 12 are placed on the longitudinal bars X2, X3, and the leg structure 12 is supported by the longitudinal bars X2, X3. In this case, the support frame 13 connected to the main body 11 is above and away from the longitudinal bars X1, X3.

[0067] Here, when the reinforcing bar binding device 10 executes the lateral movement processing, first, the position of the longitudinal bar X4 adjacent, in the Y-axis direction, to the longitudinal bar X3 on which the reinforcing bar binding device 10 is traveling is detected by

the sensors 18 provided on both sides of the main body 11 in the Y-axis direction. Then, the reinforcing bar binding device 10 measures a distance in the Y-axis direction between the longitudinal bar X3, on which the wheel 17 of each leg 15 forming the leg structure 12 is placed, and the longitudinal bar X4 detected as described above. The reinforcing bar binding device 10
5 determines the movement amount of the main body 11 or the leg structure 12 in the Y-axis direction in each processing described below based on the measured distance. When the reinforcing bar binding device 10 executes the lateral movement processing, first, the position of the longitudinal bar X4 adjacent, in the Y-axis direction, to the longitudinal bar X3 on which the reinforcing bar binding device 10 is traveling may be calculated by the sensors 18 provided
10 on both sides of the main body 11 in the Y-axis direction. The movement amount of the main body 11 or the leg structure 12 in the Y-axis direction is calculated based on information related to a distance in the Y-axis direction from a center position of the reinforcing bar binding device 10 (a position of the binding mechanism 70, which is a position of the longitudinal bar X1 detected by the sensor 16) to the positions of the sensors 18, and information related to a
15 distance in the Y-axis direction from the positions of the sensors 18 to a position of the longitudinal bar X3. Note that, for example, when the sensor 18 is mounted at a position "100" away from the center position of the reinforcing bar binding device 10 (the position of longitudinal bar X1) and the longitudinal bar X3 is at a position "20" away from the sensor 18 and close to the reinforcing bar binding device 10 (a position close to the longitudinal bar X1),
20 the reinforcing bar binding device 10 controls the movement amount of the main body 11 or leg structure 12 in the Y-axis direction in each processing described below to be "80". For example, when the sensor 18 is mounted at a position "100" away from the center position of the reinforcing bar binding device 10 (the position of longitudinal bar X1) and the longitudinal bar X3 is at a position "20" away from the sensor 18 and far from the reinforcing bar binding
25 device 10 (a position far from the longitudinal bar X1), the reinforcing bar binding device 10 controls the movement amount of the main body 11 or leg structure 12 in the Y-axis direction in each processing described below to be "120". When the positions of the sensors 18 are fixed, the information related to the distance in the Y-axis direction from the center position of the reinforcing bar binding device 10 to the positions of the sensors 18 may be stored in advance
30 in a memory as initial information. The information related to the distance in the Y-axis direction from the positions of the sensors 18 to the position of the longitudinal bar X3 may be calculated from the position of the longitudinal bar X3 detected by the sensors 18.

[0068] That is, as shown in FIGS. 17A and 17B, the reinforcing bar binding device 10 first

drives the lateral movement roller 33 in the forward direction, and moves the main body 11 in the Y-axis direction relative to the leg structure 12 while supporting the leg structure 12 by bringing each leg 15 forming the leg structure 12 into contact with the longitudinal bars X2, X3. As a result, the main body 11 approaches the longitudinal bar X4 adjacent in the Y-axis direction to the longitudinal bar X3 on which the legs 15 are placed.

[0069] Next, as shown in FIGS. 18A and 18B, the reinforcing bar binding device 10 retracts each leg 15 forming the leg structure 12, thereby lowering the height of the main body 11 relative to the longitudinal bars X1, X3. Then, the reinforcing bar binding device 10 brings the support frame 13 connected to the main body 11 into contact with the longitudinal bars X1, X3.

In this case, the support frame 13 is placed so as to straddle two longitudinal bars X1, X3, including the longitudinal bar X1 on which the reinforcing bar binding device 10 is traveling and the longitudinal bar X3 adjacent to the longitudinal bar X1 in the Y-axis direction. When the reinforcing bar binding device 10 further retracts each leg 15 forming the leg structure 12 from the state in which the support frame 13 is in contact with the longitudinal bars X1, X3, each leg 15 moves away from the longitudinal bars X2, X3 (corresponding to first processing).

[0070] Next, as shown in FIGS. 19A and 19B, the reinforcing bar binding device 10 drives the lateral movement roller 33 in the reverse direction, and moves the leg structure 12 in the Y-axis direction relative to the main body 11 while supporting the main body 11 by bringing the support frame 13 into contact with the longitudinal bars X3, X4 (corresponding to second processing). As a result, each leg 15 forming the leg structure 12 is disposed to face the longitudinal bars X1, X4 in the Z-axis direction.

[0071] Next, as shown in FIGS. 20A and 20B, the reinforcing bar binding device 10 extends each leg 15 forming the leg structure 12 and brings each leg 15 into contact with the longitudinal bars X1, X4 (corresponding to third processing). Then, when the reinforcing bar binding device 10 further extends each leg 15 forming the leg structure 12 from the state in which each leg 15 is in contact with the longitudinal bars X1, X4, the support frame 13 connected to the main body 11 moves upward away from the longitudinal bars X3, X4.

[0072] Next, as shown in FIGS. 21A and 21B, the reinforcing bar binding device 10 drives the lateral movement roller 33 in the forward direction, and moves the main body 11 in the Y-axis direction relative to the leg structure 12 while supporting the leg structure 12 by bringing each leg 15 forming the leg structure 12 into contact with the longitudinal bars X1, X4 (corresponding to fourth processing). In this way, a relative position between the main body 11 and the leg structure 12 in the Y-axis direction is returned to an initial state.

[0073] Next, effects of the reinforcing bar binding device 10 of the present embodiment will be described, focusing in particular on effects when the reinforcing bar binding device 10 performs the lateral movement processing.

[0074] When performing the lateral movement processing, the reinforcing bar binding
5 device 10 of the present embodiment repeats the processing of moving the leg structure 12 in the Y-axis direction relative to the main body 11 while supporting the main body 11 by bringing the support frame 13 into contact with the longitudinal bars X1, X3 or the longitudinal bars X3, X4, and the processing of moving the main body 11 in the Y-axis direction relative to the leg structure 12 while supporting the leg structure 12 by bringing the leg structure 12 into contact
10 with the longitudinal bars X2, X3 or the longitudinal bars X1, X4. In other words, the reinforcing bar binding device 10 can move in the Y-axis direction efficiently by moving in stages in the Y-axis direction. By moving in the Y-axis direction in stages, the reinforcing bar binding device 10 can reduce a weight of an object moved in one time of movement, and reduce a drive load on the lateral movement rollers 33. By moving in the Y-axis direction in stages, as
15 compared with a case where the movement in the Y-axis direction is performed all at once, the reinforcing bar binding device 10 can prevent angular moment around the legs 15 supported by the longitudinal bars X2, X3 or the longitudinal bars X1, X4, and can more stably perform the lateral movement processing.

[0075] In addition, each leg 15 forming the leg structure 12 includes the restricting link
20 mechanism 45 to restrict the movement direction of the wheel 17. Therefore, the wheel 17 can be stably moved in a direction approaching or moving away from the longitudinal bars X2, X3 or the longitudinal bars X1, X4. Therefore, the reinforcing bar binding device 10 can prevent the wheels 17 from accidentally colliding with the longitudinal bars X2, X3 or the longitudinal bars X1, X4 when the wheels 17 move away from the longitudinal bars X2, X3 or the
25 longitudinal bars X1, X4 in the Y-axis direction, and can stably perform the lateral movement processing of the reinforcing bar binding device 10.

[0076] When performing the lateral movement processing, if it is detected, based on the motor load of the motor driving the lateral movement roller 33, that the wheel 17 collides with the longitudinal bars X2, X3 or the longitudinal bars X1, X4, the reinforcing bar binding device
30 10 further drives the lateral movement roller 33 in a direction of moving the wheel 17 away from the longitudinal bars X2, X3 in the Y-axis direction. Therefore, the reinforcing bar binding device 10 can perform the lateral movement processing more stably.

[0077] When the reinforcing bar binding device 10 moves forward, for the legs 15 positioned

at the front side of the reinforcing bar binding device 10 among the plurality of legs 15 forming the leg structure 12, the reinforcing bar binding device 10 drives the motor 51 that controls the extension and retraction of each leg 15 so that the connection point between the first link 42 positioned at the first end and the second link 43 positioned at the second end is disposed at the front side of the reinforcing bar binding device 10 within the displacement mechanism 41. The reinforcing bar binding device 10 then determines whether the reinforcing bar binding device 10 collides with an obstacle based on a change in the load of the motor that moves the reinforcing bar binding device 10 forward. Therefore, the reinforcing bar binding device 10 can determine whether the reinforcing bar binding device 10 collides with an obstacle when the reinforcing bar binding device 10 moves forward, without providing a new sensor.

[0078] When the reinforcing bar binding device 10 accelerates or decelerates forward, for the legs 15 positioned at the front side of the reinforcing bar binding device 10 among the plurality of legs 15 forming the leg structure 12, the reinforcing bar binding device 10 drives the motor 51 that controls the extension and retraction of the leg 15 so that the connection point between the first link 42 positioned at the first end and the second link 43 positioned at the second end among the plurality of links forming the displacement mechanism 41 is disposed at the front side of the reinforcing bar binding device 10 within the displacement mechanism 41. For the legs 15 positioned at a rear side of the reinforcing bar binding device 10 among the plurality of legs 15 forming the leg structure 12, the reinforcing bar binding device 10 drives the motor 51 that controls the extension and retraction of the leg 15, ensuring the connection point between the first link 42 positioned at the first end and the second link 43 positioned at the second end among the plurality of links forming the displacement mechanism 41 is disposed at the rear side of the reinforcing bar binding device 10 within the displacement mechanism 41. Therefore, when the reinforcing bar binding device 10 accelerates or decelerates forward, the height of the main body 11 can be prevented from fluctuating due to the extension and retraction of each leg 15 forming the leg structure 12.

[0079] Next, the effects of the reinforcing bar binding device 10 of the present embodiment will be described, focusing in particular on effects when the reinforcing bar binding device 10 performs the binding processing.

[0080] The reinforcing bar binding device 10 of the present embodiment extends the legs 15 and causes the coil spring 50 to apply a biasing force in a direction of moving the wheels 17 close to the longitudinal bars X1, X2, and X3. Therefore, even if a center of gravity of the main body 11 moves up and down as the wire used for binding is consumed while the binding of the

reinforcing bars progresses, the biasing force from the coil spring 50 acts in response to the movement of the center of gravity of the main body 11, so that the reinforcing bar binding device 10 can maintain the posture of the main body 11 in a desired posture, and can accurately perform the binding of the reinforcing bars.

5 [0081] By applying a biasing force from the coil spring 50 in a direction of extending the leg 15, the reinforcing bar binding device 10 can reduce power consumption when driving the motor 51 in the direction of extending the leg 15 to support the weight of the main body 11 by the amount of the biasing force of the coil spring 50. By providing the motor 51 individually for each leg 15 and controlling the drive of each motor 51 so that the power consumption of
10 each motor 51 is minimized, the power consumption when the reinforcing bar binding device 10 performs leveling control can be further reduced.

[0082] In the reinforcing bar binding device 10 of the present embodiment, the binding mechanism 70 is inserted into the penetration 60 provided in the main body 11, and the binding mechanism 70 is configured to rotate in the circumferential direction around the opening center
15 of the penetration 60 relative to the main body 11. Therefore, the reinforcing bar binding device 10 is configured to change the orientation of the two arms of the binding portion 73 of the binding mechanism 70 when performing binding processing on the binding position where the longitudinal bar and the lateral bar intersect with each other. Therefore, the reinforcing bar binding device 10 can use the wire to perform the binding processing on the binding position
20 not only when the longitudinal bar and the lateral bar intersect with each other at a right angle, but also when the longitudinal bar and the lateral bar intersect with each other diagonally, making the binding processing highly versatile.

[0083] Note that the above embodiment can also be implemented in the following forms.

[0084] In the above embodiment, an example has been described in which the reinforcing
25 bar binding device 10 performs the lateral movement processing when moving to the longitudinal bar X4 adjacent to the longitudinal bar X3 by which the leg 15 is supported. However, the present invention is not limited to the case where the reinforcing bar binding device 10 performs the lateral movement processing. For example, when the position of the binding portion 73 of the binding mechanism 70 and the position of the binding position do not
30 coincide in the Y-axis direction when the reinforcing bar binding device 10 reaches the binding position, the position of the binding mechanism 70 in the Y-axis direction may be finely adjusted in a manner similar to the lateral movement processing described above. That is, by the reinforcing bar binding device 10 repeating the processing of moving the leg structure 12

in the Y-axis direction relative to the main body 11 while supporting the main body 11 by bringing the support frame 13 into contact with the longitudinal bars X1, X3, and the processing of moving the main body 11 in the Y-axis direction relative to the leg structure 12 while supporting the leg structure 12 by bringing the leg structure 12 into contact with the longitudinal bars X2, X3, the position of the binding mechanism 70 in the Y-axis direction may be finely adjusted.

[0085] [Appendix]

Technical ideas that can be understood from the above-described embodiment will be described below.

10 [0086] [Appendix 1]

A reinforcing bar binding device, including:

a binding mechanism configured to bind a binding position where a reinforcing bar extending in a first direction and a reinforcing bar extending in a second direction intersect with each other;

15 a main body to which the binding mechanism is mounted;

a leg configured to travel along the reinforcing bar extending in the first direction;

a first drive unit configured to move the leg away from the reinforcing bar;

a second drive unit configured to move the leg in the second direction intersecting the first direction; and

20 a control unit configured to control the first drive unit and the second drive unit,

in which the control unit first controls the first drive unit to move the leg away from the reinforcing bar, and then controls the second drive unit to move the leg in the second direction.

[0087] [Appendix 2]

25 The reinforcing bar binding device according to Appendix 1, further including:

a support portion connected to the main body,

in which the leg is movably connected to the main body in the second direction, and

in which the control unit is configured to execute:

30 first processing of, assuming that the reinforcing bar on which the leg is supported as a first reinforcing bar, controlling the first drive unit to move the leg away from the first reinforcing bar while the support portion remains in contact with the first reinforcing bar;

second processing of controlling the second drive unit to move the leg in

the second direction relative to the main body after moving the leg away from the first reinforcing bar;

third processing of controlling the first drive unit to bring the leg into contact with a second reinforcing bar positioned adjacent to the first reinforcing bar in the second direction; and

fourth processing of moving the main body in the second direction relative to the leg.

[0088] [Appendix 3]

The reinforcing bar binding device according to Appendix 2,

in which the control unit repeats the first processing and the second processing a plurality of times to position the leg to face the second reinforcing bar in a height direction of the main body.

[0089] [Appendix 4]

The reinforcing bar binding device according to Appendix 3,

in which in repeating the first processing and the second processing a plurality of times, the control unit moves the leg in the second direction by approximately the same distance each time.

[0090] [Appendix 5]

The reinforcing bar binding device according to any one of Appendix 1 to Appendix 4,

in which the second drive unit includes a rail-shaped meshing portion provided on one side of either the main body or the leg, and a drive gear provided on the other side of either the main body or the leg and configured to mesh with the meshing portion, and

in which the control unit is configured to:

in a case of moving the main body in the second direction relative to the leg, drive the drive gear in a first drive direction while the drive gear remains meshed with the meshing portion; and

in a case of moving the leg in the second direction relative to the main body, drive the drive gear in a second drive direction while the drive gear remains meshed with the meshing portion.

[0091] [Appendix 6]

The reinforcing bar binding device according to any one of Appendix 1 to Appendix 5,

in which the control unit determines whether the leg is away from the reinforcing bar based on whether a drive amount of the first drive unit reaches a predetermined threshold.

[0092] [Appendix 7]

The reinforcing bar binding device according to any one of Appendix 1 to Appendix 5 6, further including:

a first detection unit configured to detect a reinforcing bar adjacent to the reinforcing bar in the second direction in a case where the reinforcing bar binding device moves along a reinforcing bar extending in the first direction,

in which the control unit determines a distance for moving the leg in the second 10 direction based on a detection result of the reinforcing bar by the first detection unit.

[0093] [Appendix 8]

The reinforcing bar binding device according to any one of Appendix 1 to Appendix 7, further including:

a second detection unit used to calculate the binding position,
15 in which in a case where the reinforcing bar binding device moves to an adjacent reinforcing bar in the second direction, the control unit adjusts a movement amount in the second direction as the reinforcing bar binding device moves toward the binding position based on a position of the adjacent reinforcing bar detected by the second detection unit.

[0094] [Appendix 9]

The reinforcing bar binding device according to any one of Appendix 1 to Appendix 20 8, further including:

a support portion connected to the main body,
in which the first drive unit is configured to extend and retract the leg, and
in which the control unit is configured to:
25 control the first drive unit so that when the leg is extended, the leg comes into contact with the reinforcing bar and the support portion is moved away from the reinforcing bar; and

control the first drive unit so that when the leg is retracted, the support portion comes into contact with the reinforcing bar and the leg is moved away from the 30 reinforcing bar.

[0095] [Appendix 10]

A reinforcing bar binding device, including:

a binding mechanism configured to bind a position where a reinforcing bar extending

in a first direction and a reinforcing bar extending in a second direction intersect;

a main body to which the binding mechanism is mounted;

a detection unit configured to detect the reinforcing bar adjacent to the main body in the second direction; and

5 a moving mechanism configured to move the main body in the second direction,
in which the moving mechanism includes a movement amount calculation unit
configured to calculate a movement amount of the main body in the second direction based on
a position of the reinforcing bar detected by the detection unit.

[0096] The present embodiment has been described above with reference to specific
10 examples. However, the present disclosure is not limited to these specific examples. Design
changes made by those skilled in the art as appropriate to these specific examples are also
included within the scope of the present disclosure as long as the changes have characteristics
of the present disclosure. Elements, arrangements, conditions, shapes, and the like included in
the specific examples described above are not limited to those illustrated, and can be
15 appropriately changed. The elements included in each of the specific examples described above
can be appropriately combined as long as no technical contradiction occurs.

[0097] The present application is based on Japanese Patent Application No. 2023-007176
filed on January 20, 2023, and contents thereof are incorporated herein by reference.

20 INDUSTRIAL APPLICABILITY

[0098] The reinforcing bar binding device of the present disclosure is capable of precise
movement in a lateral direction.

CLAIMS

[Claim 1] A reinforcing bar binding device, comprising:

a binding mechanism configured to bind a binding position where a reinforcing bar extending in a first direction and a reinforcing bar extending in a second direction intersect with each other;

a main body to which the binding mechanism is mounted;

a leg configured to travel along the reinforcing bar extending in the first direction;

a first drive unit configured to move the leg away from the reinforcing bar;

a second drive unit configured to move the leg in the second direction intersecting the first direction relative to the main body; and

a control unit configured to control the first drive unit and the second drive unit,

wherein the control unit first controls the first drive unit to move the leg away from the reinforcing bar, and then controls the second drive unit to move the leg in the second direction.

[Claim 2] The reinforcing bar binding device according to claim 1, further comprising:

a support portion connected to the main body,

wherein the leg is movably connected to the main body in the second direction, and

wherein the control unit is configured to execute:

first processing of, assuming that the reinforcing bar on which the leg is supported as a first reinforcing bar, controlling the first drive unit to move the leg away from the first reinforcing bar while the support portion remains in contact with the first reinforcing bar;

second processing of controlling the second drive unit to move the leg in the second direction relative to the main body after moving the leg away from the first reinforcing bar;

third processing of controlling the first drive unit to bring the leg into contact with a second reinforcing bar positioned adjacent to the first reinforcing bar in the second direction; and

fourth processing of moving the main body in the second direction relative to the leg.

[Claim 3] The reinforcing bar binding device according to claim 2,

wherein the control unit repeats the second processing and the fourth processing a

plurality of times to position the leg to face the second reinforcing bar in a height direction of the main body.

[Claim 4] The reinforcing bar binding device according to claim 3,

wherein in repeating the second processing and the fourth processing a plurality of times, the control unit moves the leg in the second direction by approximately the same distance each time.

[Claim 5] The reinforcing bar binding device according to claim 1,

wherein the second drive unit includes a rail-shaped meshing portion provided on one side of either the main body or the leg, and a drive gear provided on the other side of either the main body or the leg and configured to mesh with the meshing portion, and

wherein the control unit is configured to:

in a case of moving the main body in the second direction relative to the leg, drive the drive gear in a first drive direction while the drive gear remains meshed with the meshing portion; and

in a case of moving the leg in the second direction relative to the main body, drive the drive gear in a second drive direction while the drive gear remains meshed with the meshing portion.

[Claim 6] The reinforcing bar binding device according to claim 1,

wherein the control unit determines whether the leg is away from the reinforcing bar based on whether a drive amount of the first drive unit reaches a predetermined threshold.

[Claim 7] The reinforcing bar binding device according to claim 1, further comprising:

a first detection unit configured to detect a reinforcing bar adjacent to the reinforcing bar in the second direction in a case where the reinforcing bar binding device moves along a reinforcing bar extending in the first direction,

wherein the control unit determines a distance for moving the leg in the second direction based on a detection result of the reinforcing bar by the first detection unit.

[Claim 8] The reinforcing bar binding device according to claim 1, further comprising:

a second detection unit used to calculate the binding position,

wherein in a case where the reinforcing bar binding device moves to an adjacent reinforcing bar in the second direction, the control unit adjusts a movement amount in the second direction as the reinforcing bar binding device moves toward the binding position, based

on a position of the adjacent reinforcing bar detected by the second detection unit.

[Claim 9] The reinforcing bar binding device according to claim 1, further comprising:

- 5 a support portion connected to the main body,
- wherein the first drive unit is configured to extend and retract the leg, and
- wherein the control unit is configured to:
 - control the first drive unit so that when the leg is extended, the leg comes
 - into contact with the reinforcing bar and the support portion is moved away from the reinforcing
 - bar; and
 - 10 control the first drive unit so that when the leg is retracted, the support
 - portion comes into contact with the reinforcing bar and the leg is moved away from the
 - reinforcing bar.

[Claim 10] A reinforcing bar binding device, comprising:

- a binding mechanism configured to bind a position where a reinforcing bar extending
- 15 in a first direction and a reinforcing bar extending in a second direction intersect;
- a main body to which the binding mechanism is mounted;
- a detection unit configured to detect the reinforcing bar adjacent to the main body in
- the second direction; and
- a moving mechanism configured to move the main body in the second direction,
- 20 wherein the moving mechanism includes a movement amount calculation unit
- configured to calculate a movement amount of the main body in the second direction based on
- a position of the reinforcing bar detected by the detection unit.
