NOVEL OXADIAZOLE DERIVATIVES AND THEIR USE AS POSITIVE ALLOSTERIC MODULATORS OF METABOTROPIC GLUTAMATE RECEPTORS

FIELD OF THE INVENTION

I

The present invention provides new compounds of formula I as positive allosteric modulators of metabotropic receptors – subtype 5 ("mGluR5") which are useful for the treatment or prevention of central nervous system disorders such as for example: cognitive decline, both positive and negative symptoms in schizophrenia as well as various other central or peripheral nervous system disorders in which the mGluR5 subtype of glutamate metabotropic receptor is involved. The invention is also directed to pharmaceutical compounds and compositions in the prevention or treatment of such diseases in which mGluR5 is involved.

BACKGROUND OF THE INVENTION

Glutamate, the major amino-acid transmitter in the mammalian central nervous system (CNS), mediates excitatory synaptic neurotransmission through the activation of ionotropic glutamate receptors receptor-channels (iGluRs, namely NMDA, AMPA and kainate) and metabotropic glutamate receptors (mGluRs). iGluRs are responsible for fast excitatory transmission (Nakanishi S et al., (1998) Brain Res. Rev., 26:230-235) while mGluRs have a more modulatory role that contributes to the fine-tuning of synaptic efficacy. Glutamate performs numerous physiological functions such as long-term potentiation (LTP), a process believed to underlie learning and memory but also cardiovascular regulation, sensory perception, and the development of synaptic plasticity. In addition, glutamate plays an important role in the patho-physiology of different neurological and psychiatric diseases, especially when an imbalance in glutamatergic neurotransmission occurs.

The mGluRs are seven-transmembrane G protein-coupled receptors. The eight members of the family are classified into three groups (Groups I, II & III) according to their sequence homology and pharmacological properties (Schoepp DD et al. (1999) Neuropharmacology, 38:1431-1476). Activation of mGluRs lead to a large variety of intracellular responses and activation of different transductional cascades. Among mGluR members, the mGluR5 subtype is of high interest for counterbalancing the deficit or excesses of neurotransmission in neuropsychatric diseases. mGluR5 belongs to Group I and its activation initiates cellular responses through G-protein mediated mechanisms. mGluR5 is coupled to phospholipase C and stimulates phosphoinositide hydrolysis and intracellular calcium mobilization.

mGluR5 proteins have been demonstrated to be localized in post-synaptic elements adjacent to the post-synaptic density (Lujan R et al. (1996) Eur. J. Neurosci., 8:1488-

500; Lujan R et al. (1997) J. Chem. Neuroanat., 13:219-41) and are rarely detected in the pre-synaptic elements (Romano C et al. (1995) J. Comp. Neurol., 355:455-69). mGluR5 receptors can therefore modify the post-synaptic responses to neurotransmitter or regulate neurotransmitter release.

In the CNS, mGluR5 receptors are abundant mainly throughout the cortex, hippocampus, caudate-putamen and nucleus accumbens. As these brain areas have been shown to be involved in emotion, motivational processes and in numerous aspects of cognitive function, mGluR5 modulators are predicted to be of therapeutic interest.

A variety of potential clinical indications have been suggested to be targets for the development of subtype selective mGluR modulators. These include epilepsy, neuropathic and inflammatory pain, numerous psychiatric disorders (eg anxiety and schizophrenia), movement disorders (eg Parkinson disease), neuroprotection (stroke and head injury), migraine and addiction/drug dependency (for reviews, see Brauner-Osborne H et al. (2000) J. Med. Chem., 43:2609-45; Bordi F and Ugolini A. (1999) Prog. Neurobiol., 59:55-79; Spooren W et al. (2003) Behav. Pharmacol., 14:257-77).

The hypothesis of hypofunction of the glutamatergic system as reflected by NMDA receptor hypofunction as a putative cause of schizophrenia has received increasing support over the past few years (Goff DC and Coyle JT (2001) Am. J. Psychiatry, 158:1367-1377; Carlsson A et al. (2001) Annu. Rev. Pharmacol. Toxicol., 41:237-260 for a review). Evidence implicating dysfunction of glutamatergic neurotransmission is supported by the finding that antagonists of the NMDA subtype of glutamate receptor can reproduce the full range of symptoms as well as the physiologic manifestation of schizophrenia such as hypofrontality, impaired prepulse inhibition and enhanced subcortical dopamine release. In addition, clinical studies have suggested that mGluR5 allele frequency is associated with schizophrenia among certain cohorts (Devon RS et al. (2001) Mol. Psychiatry., 6:311-4) and that an increase in mGluR5 message has been found in cortical pyramidal cells layers of schizophrenic brain (Ohnuma T et al. (1998) Brain Res. Mol. Brain Res., 56:207-17).

The involvement of mGluR5 in neurological and psychiatric disorders is supported by evidence showing that in vivo activation of group I mGluRs induces a potentiation of NMDA receptor function in a variety of brain regions mainly through the activation of mGluR5 receptors (Mannaioni G et al. (2001) Neurosci., 21:5925-34; Awad H et al. (2000) J. Neurosci., 20:7871-7879; Pisani A et al. (2001) Neuroscience, 106:579-87; Benquet P et al (2002) J. Neurosci., 22:9679-86).

The role of glutamate in memory processes also has been firmly established during the past decade (Martin SJ et al. (2000) Annu. Rev. Neurosci., 23:649-711; Baudry M and Lynch G. (2001) Neurobiol. Learn. Mem., 76:284-297). The use of mGluR5 null mutant mice have strongly supported a role of mGluR5 in learning and memory. These mice show a selective loss in two tasks of spatial learning and memory, and reduced CA1 LTP (Lu et al. (1997) J. Neurosci., 17:5196-5205; Schulz B et al. (2001) Neuropharmacology, 41:1-7; Jia Z et al. (2001) Physiol. Behav., 73:793-802; Rodrigues et al. (2002) J. Neurosci., 22:5219-5229).

The finding that mGluR5 is responsible for the potentiation of NMDA receptor mediated currents raises the possibility that agonists of this receptor could be useful as cognitive-enhancing agents, but also as novel antipsychotic agents that act by selectively enhancing NMDA receptor function.

The activation of NMDARs could potentiate hypofunctional NMDARs in neuronal circuitry relevant to schizophrenia. Recent in vivo data strongly suggest that mGluR5 activation may be a novel and efficacious approach to treat cognitive decline and both positive and negative symptoms in schizophrenia (Kinney GG et al. (2003) J. Pharmacol. Exp. Ther., 306(1):116-123).

mGluR5 receptor is therefore being considered as a potential drug target for treatment of psychiatric and neurological disorders including treatable diseases in this connection are anxiety disorders, attentional disorders, eating disorders, mood disorders, psychotic disorders, cognitive disorders, personality disorders and substance-related disorders.

Most of the current modulators of mGluR5 function have been developed as structural analogues of glutamate, quisqualate or phenylglycine (Schoepp DD et al. (1999) Neuropharmacology, 38:1431-1476) and it has been very challenging to develop in vivo active and selective mGluR5 modulators acting at the glutamate binding site. A new avenue for developing selective modulators is to identify molecules that act through allosteric mechanisms, modulating the receptor by binding to site different from the highly conserved orthosteric binding site.

Positive allosteric modulators of mGluRs have emerged recently as novel pharmacological entities offering this attractive alternative. This type of molecule has been discovered for mGluR1, mGluR2, mGluR4, and mGluR5 (Knoflach F et al. (2001) Proc. Natl. Acad. Sci. U S A., 98:13402-13407; O'Brien JA et al. (2003) Mol. Pharmacol., 64:731-40 ; Johnson K et al. (2002) Neuropharmacology, 43:291; Johnson MP et al. (2003) J. Med. Chem., 46:3189-92; Marino MJ et al. (2003) Proc. Natl. Acad. Sci. U S A., 100(23):13668-73; for a review see Mutel V (2002) Expert Opin. Ther. Patents, 12:1-8; Kew JN (2004) Pharmacol. Ther., 104(3):233-44; Johnson MP et al. (2004) Biochem. Soc. Trans., 32:881-7). DFB and related molecules were described as in vitro mGluR5 positive allosteric modulators but with low potency (O'Brien JA et al. (2003) Mol. Pharmacol., 64:731-40). Benzamide derivatives have been patented (WO 2004/087048; O'Brien JA (2004) J. Pharmacol. Exp. Ther., 309:568-77) and recently aminopyrazole derivatives have been disclosed as mGluR5 positive allosteric modulators (Lindsley et al. (2004) J. Med. Chem., 47:5825-8; WO 2005/087048). Among aminopyrazole derivatives, CDPPB has shown in vivo activity antipsychotic-like effects in rat behavioral models (Kinney GG et al. (2005) J. Pharmacol. Exp. Ther., 313:199-206). This report is consistent with the hypothesis that allosteric potentiation of mGluR5 may provide a novel approach for development of antipsychotic agents. Recently a novel series of positive allosteric modulators of mGluR5 receptors has been disclosed (WO 2005/044797).
Aryloxadiazole derivatives have been disclosed (WO 04/014902 and WO 04/14881) ; these compounds are negative allosteric modulators of mGluR5 receptors. International Publication N° WO 01/54507 by Akkadix Corp. discloses 4-oxadiazolyl piperidine as anthelmintics. International Publication N° WO 03/002559 by Smith

Kline Beecham laboratories discloses oxadiazolyl alkyl piperidine as orexin receptor antagonists.

None of the specifically disclosed compounds are structurally related to the compounds of the present invention.

The present invention relates to a method of treating or preventing a condition in a mammal, including a human, the treatment or prevention of which is affected or facilitated by the neuromodulatory effect of mGluR5 positive allosteric modulators.

The present invention relates to the pharmaceutically acceptable acid addition salts of compounds of the formula I or pharmaceutically acceptable carriers or excipients.

The present invention relates to a method of treating or preventing a condition in a mammal, including a human, the treatment or prevention of which is affected or facilitated by the neuromodulatory effect of mGluR5 allosteric modulators and particularly positive allosteric modulators.

The present invention relates to a method useful for treating or preventing various peripheral and central nervous system disorders such as tolerance or dependence, anxiety, depression, psychiatric disease such as psychosis, inflammatory or neuropathic pain, memory impairment, Alzheimer's disease, ischemia, drug abuse and addiction, as defined in the attached claims.

The present invention relates to pharmaceutical compositions which provide from about 0.01 to 1000 mg of the active ingredient per unit dose. The compositions may be administered by any suitable route. For example orally in the form of capsules or tablets, parenterally in the form of solutions for injection, topically in the form of onguents or lotions, ocularly in the form of eye-lotion, rectally in the form of suppositories.

The pharmaceutical formulations of the invention may be prepared by conventional methods in the art; the nature of the pharmaceutical composition employed will depend on the desired route of administration. The total daily dose usually ranges from about 0.05 – 2000 mg.

METHODS OF SYNTHESIS

Compounds of general formula I may be prepared by methods known in the art of organic synthesis as set forth in part by the following synthesis schemes. In all of the schemes described below, it is well understood that protecting groups for sensitive or reactive groups are employed where necessary in accordance with general principles of chemistry. Protecting groups are manipulated according to standard methods of organic synthesis (Green T.W. and Wuts P.G.M. (1991) *Protecting Groups in Organic Synthesis,* John Wiley et Sons). These groups are removed at a convenient stage of the compound synthesis using methods that are readily apparent to those skilled in the art. The selection of process as well as the reaction conditions and order of their execution shall be consistent with the preparation of compounds of formula I.
The compound of formula I may be represented as a mixture of enantiomers, which may be resolved into the individual pure *R*- or *S*-enantiomers. If for instance, a

particular enantiomer of the compound of formula I is desired, it may be prepared by asymmetric synthesis, or by derivation with a chiral auxiliary, where the resulting diastereomeric mixture is separated and the auxiliary group cleaved to provided the pure desired enantiomers. Alternatively, where the molecule contains a basic functional group such as amino, or an acidic functional group such as carboxyl, this resolution may be conveniently performed by fractional crystallization from various solvents, of the salts of the compounds of formula I with optical active acid or by other methods known in the literature, e.g. chiral column chromatography.
Resolution of the final product, an intermediate or a starting material may be performed by any suitable method known in the art as described by Eliel E.L., Wilen S.H. and Mander L.N. (1984) *Stereochemistry of Organic Compounds*, Wiley-Interscience.
Many of the heterocyclic compounds of formula I can be prepared using synthetic routes well known in the art (Katrizky A.R. and. Rees C.W. (1984) *Comprehensive Heterocyclic Chemistry*, Pergamon Press).
The product from the reaction can be isolated and purified employing standard techniques, such as extraction, chromatography, crystallization, distillation, and the like.

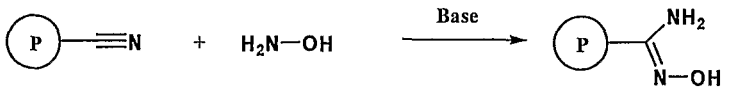

The compounds of formula **I** wherein W is a 3-substituted piperidine ring may be prepared according to the synthetic sequences illustrated in the Schemes 1-4.

Wherein

P and Q each independently is aryl or heteroaryl as described above
B represents $-C(=O)-(C_0-C_2)$alkyl-; $-S(=O)_2-(C_0-C_2)$alkyl-.

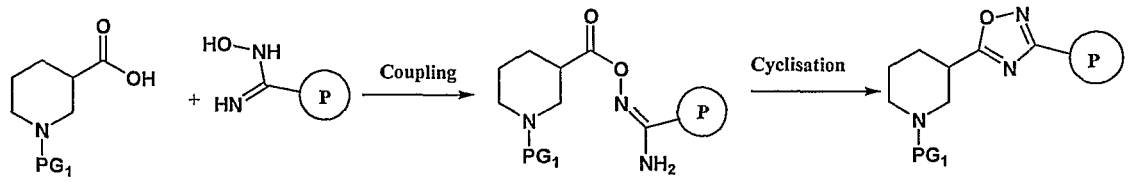

The starting material amidoxime can be prepared by methods known in the art of organic synthesis as set forth in part by the following synthesis Scheme 1.

Scheme 1

In turn, a nitrile derivative (for example 4-fluoro-benzonitrile) is reacted with hydroxylamine under neutral or basic conditions such as triethylamine, diisopropyl-ethylamine, sodium carbonate, sodium hydroxide and the like in a suitable solvent *(e.g.* methyl alcohol, ethyl alcohol). The reaction typically proceeds by allowing the reaction temperature to warm slowly from ambient temperature to a temperature range of 70°C up to 80°C inclusive for a time in the range of about 1 hour up to 48 hours inclusive (see for example Lucca, George V. De; Kim, Ui T.; Liang, Jing; Cordova, Beverly; Klabe, Ronald M.; et al; J.Med.Chem.; EN; 41; 13; 1998; 2411-2423, Lila, Christine; Gloanec, Philippe; Cadet, Laurence; Herve, Yolande; Fournier, Jean; et al.; Synth.Commun.; EN; 28; 23; 1998; 4419-4430 and see: Sendzik, Martin; Hui, Hon C.; Tetrahedron Lett.; EN; 44; 2003; 8697-8700 and references therein for reaction under neutral conditions).

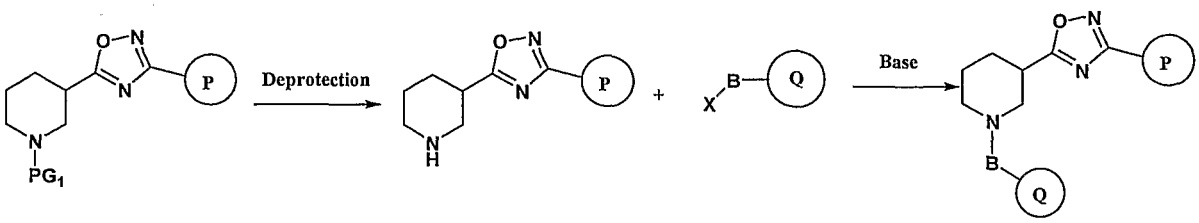

Scheme 2

The substituted amidoxime derivative (described in the Scheme 1) may be converted to an acyl-amidoxime derivative using the approach outlined in the Scheme 2. In the Scheme 2, PG_1 is an amino protecting group such as *tert*-butyloxycarbonyl, benzyloxycarbonyl, ethoxycarbonyl, benzyl and the like. The coupling reaction may be promoted by coupling agents known in the art of organic synthesis such as EDCI (1-(3-dimethylaminopropyl)-3-ethylcarbodiimide), DCC (N,N'-dicyclohexyl-carbodiimide), in the presence of a suitable base such as triethylamine, diisopropyl-ethylamine, in a suitable solvent (e.g. tetrahydrofuran, dichloromethane, N,N-dimethylformamide, dioxane). Typically, a co-catalyst such as HOBT (hydroxy-benzotriazole), HOAT (1-hydroxy-7-azabenzotriazole) may also be present in the reaction mixture. The reaction typically proceeds at a temperature in the range of ambient temperature up to 60°C inclusive for a time in the range of about 2 hours up to 12 hours to produce the intermediate acyl-amidoxime. The cyclisation reaction may be effected thermally in a temperature range of about 80°C up to about 150°C for a time in the range of about 2 hours up to 18 hours (see for example Suzuki, Takeshi; Iwaoka, Kiyoshi; Imanishi, Naoki; Nagakura, Yukinori; Miyata, Keiji; et al.; Chem.Pharm.Bull.; EN; 47; 1; 1999; 120 - 122). The product from the reaction can be isolated and purified employing standard techniques, such as extraction, chromatography, crystallization, distillation, and the like.

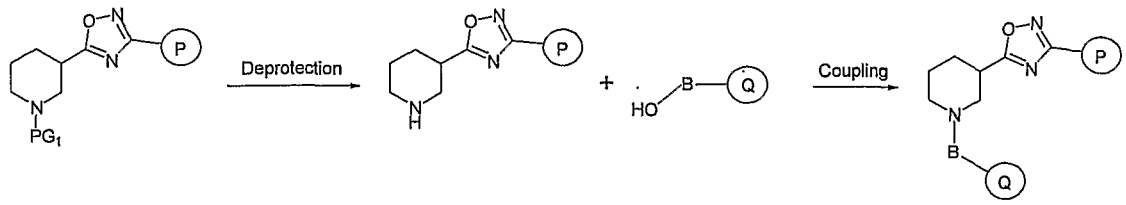

The final step may be effected either by a process described in the Scheme 3 or by a process described in the Scheme 4.

Scheme 3

As shown in the Scheme 3, protecting groups PG_1 are removed using standard methods. In the Scheme 3, B is as defined above, X is halogen, for example the piperidine derivative is reacted with an aryl or heteroaryl acyl chloride using method that are readily apparent to those skilled in the art. The reaction may be promoted by a base such as triethylamine, diisopropylamine, pyridine in a suitable solvent (*e.g.* tetrahydrofuran, dichloromethane). The reaction typically proceeds by allowing the reaction temperature to warm slowly from 0°C up to ambient temperature for a time in the range of about 4 up to 12 hours.

Scheme 4

As shown in the Scheme 4, protecting groups PG_1 are removed using standard methods. The coupling reaction may be promoted by coupling agents known in the art of organic synthesis such as EDCI (1-(3-dimethylaminopropyl)-3-ethylcarbodiimide), DCC (N,N'-dicyclohexyl-carbodiimide) or by polymer-supported coupling agents such as polymer-supported carbodiimide (PS-DCC, ex Argonaut Technologies), in the presence of a suitable base such as triethylamine, diisopropyl-ethylamine, in a suitable solvent (e.g. tetrahydrofuran, dichloromethane, N,N-dimethylformamide, dioxane). Typically, a co-catalyst such as HOBT (1-hydroxy-benzotriazole), HOAT (1-hydroxy-7-azabenzotriazole) and the like may also be present in the reaction mixture. The reaction typically proceeds at ambient temperature for a time in the range of about 2 hours up to 12 hours.

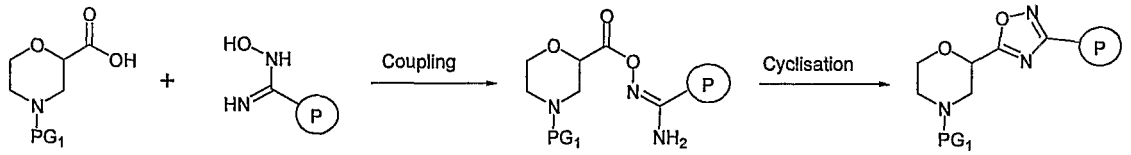

The compounds of formula **I** wherein W is a 2-substituted morpholine ring may be prepared according to the synthetic sequences illustrated in the Schemes 5-6.

Wherein

P and Q each independently is aryl or heteroaryl as described above

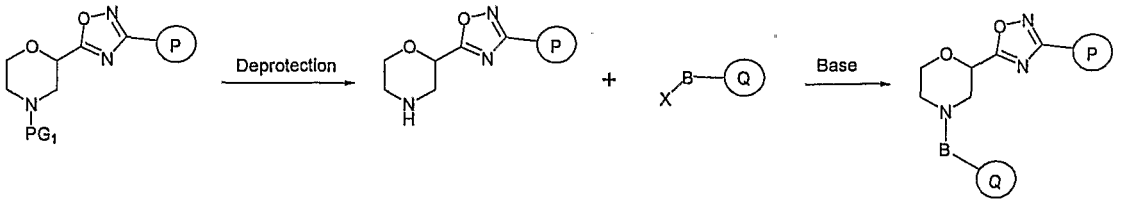

B represents $-C(=O)-(C_0-C_2)$alkyl-; $-S(=O)_2-(C_0-C_2)$alkyl-.

Scheme 5

In the Scheme 5, a substituted amidoxime derivative (described in the Scheme 1) may be converted to an acyl-amidoxime derivative, by reaction with a morpholine derivative, through a process similar to that described in the Scheme 2. Similarly, the acyl-amidoxime derivative can be cyclized to a 1,2,4-oxadiazole derivative according to a process described in the Scheme 2.

Scheme 6

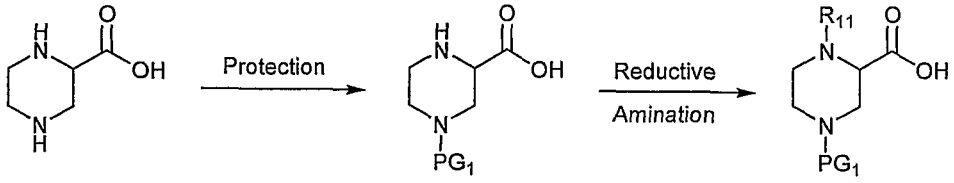

In the Scheme 6, PG_1 groups are removed using standard methods. The coupling reaction illustrated in the Scheme 6 are similar to those described in the Scheme 3 and 4 (when X = OH).

The compounds of formula **I** wherein W is a 2-substituted piperazine ring may be prepared according to the synthetic sequences illustrated in the Schemes 7-9.

Wherein

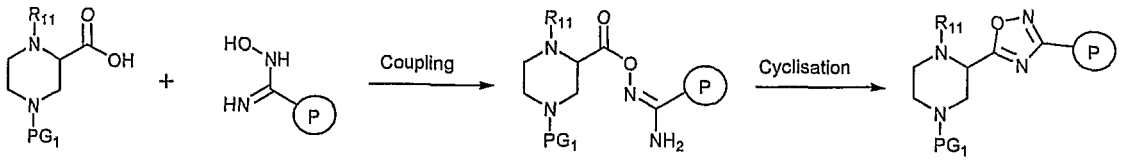

P and Q each independently is aryl or heteroaryl as described above
B represents –C(=O)-(C_0-C_2)alkyl-; -S(=O)$_2$-(C_0-C_2)alkyl-.

Scheme 7

In the Scheme 7, piperazine-2-carboxylic acid is selectively protected at the nitrogen atom at position 4. PG_1 is an amino protecting group such as t-butyloxycarbonyl and the like. This reaction may be performed using agents such as 2-(boc-oxymino)-2-phenylacetonitrile, di-tertbutyl-dicarbonate and the like in a suitable organic solvent (e.g. dioxane, tetrahydrofuran) in mixture with water. Typically, the pH of the reaction mixture will be adjusted to a value in the range of 8 to 12, by addition of a suitable base such as sodium hydroxide, potassium hydroxide, triethylamine and the like. The reaction typically proceeds at room temperature for a time in the range of about 1 hour up to 4 hours (see for example: Bigge, Christopher F.; Hays, Sheryl J.; Novak, Perry M.; Drummond, James T. et al.; Tetrahedron Letters; 30, 39; 1989; 5193-5196 and WO 2004/022061). The N^4-protected piperazine derivative can be converted to a piperazine derivative substituted at position 1, using standard conditions for reductive amination. R_{11} may be for instance C_1-C_6-alkyl, C_3-C_6-cycloalkyl, C_3-C_7-cycloalkylalkyl, arylalkyl, heteroarylalkyl. The reaction may be performed by reacting the N^4-protected piperazine derivative with an aldehyde or a ketone (for example, formaldehyde), in the presence of a suitable reducing agent such as sodium triacetoxy-borohydride, sodium cyano-borohydride, sodium borohydride and the like, in a suitable solvent such as acetonitrile, tetrahydrofuran, methanol, ethanol, 1,2-dichloroethane and the like. Typically, addition of an acid to decrease the pH of the reaction mixture to a pH of less than about 7 may be necessary to effect reaction, wherein the acid is added as needed and the acid is such as acetic acid, hydrochloric acid and the like. The reaction typically proceeds at room temperature for a time in the range of about 2 hours up to 4 hours.

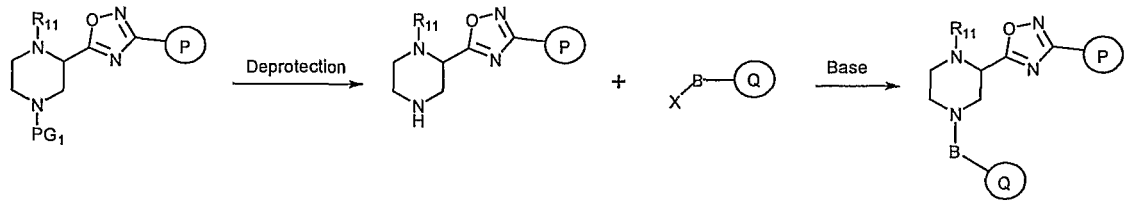

Scheme 8

In the Scheme 8, a substituted amido-oxime derivative (described in the Scheme 1) may be converted to an acyl-amido-oxime derivative, by reaction with a piperazine derivative (as described in the Scheme 8), through a process similar to that described

in the Scheme 2. Similarly, the acyl-amido-oxime derivative can be cyclized to a 1,2,4-oxadiazole derivative according to a process described in the Scheme 2.

Scheme 9

In the Scheme 9, PG_1 groups are removed using standard methods. The coupling reaction illustrated in the Scheme 9 is similar to those described in the Scheme 3 and 4 (X = halogen, OH).

The compounds of Formula **I** which are basic in nature can form a wide variety of different pharmaceutically acceptable salts with various inorganic and organic acids. PHARMACOLOGY:

The compounds provided in the present invention are positive allosteric modulators of mGluR5. As such, these compounds do not appear to bind to the orthosteric glutamate recognition site, and do not activate the mGluR5 by themselves. Instead, the response of mGluR5 to a concentration of glutamate or mGluR5 agonist is increased when compounds of Formula I are present. Compounds of Formula I are expected to have their effect at mGluR5 by virtue of their ability to enhance the function of the receptor.

EXAMPLE A

mGluR5 assay on rat cultured cortical astrocytes

Under exposure to growth factors (basic fibroblast growth factor, epidermal growth factor), rat cultured astrocytes express group I-Gq coupled mGluR transcripts, namely mGluR5, but none of the splice variants of mGluR1, and as a consequence, a functional expression of mGluR5 receptors (Miller et al. (1995) J. Neurosci. 15:6103-9): The stimulation of mGluR5 receptors with selective agonist CHPG and the full blockade of the glutamate-induced phosphoinositide (PI) hydrolysis and subsequent intracellular calcium mobilization with specific antagonist as MPEP confirm the unique expression of mGluR5 receptors in this preparation.
This preparation was established and used in order to assess the properties of the compounds of the present invention to increase the Ca^{2+} mobilization-induced by glutamate without showing any significant activity when applied in the absence of glutamate.

Primary cortical astrocytes culture:

Primary glial cultures were prepared from cortices of Sprague-Dawley 16 to 19 days old embryos using a modification of methods described by Mc Carthy and de Vellis (1980) J. Cell Biol. 85:890-902 and Miller et al. (1995) J. Neurosci. 15(9):6103-9. The cortices were dissected and then dissociated by trituration in a sterile buffer containing 5.36 mM KCl, 0.44 mM $NaHCO_3$, 4.17 mM KH_2PO_4, 137 mM NaCl, 0.34 mM NaH_2PO_4, 1 g/L glucose. The resulting cell homogenate was plated onto poly-D-lysine precoated T175 flasks (BIOCOAT, Becton Dickinson Biosciences, Erembodegem, Belgium) in Dubelcco's Modified Eagle's Medium (D-MEM GlutaMAX™ I, Invitrogen, Basel, Switzerland) buffered with 25 mM HEPES and 22.7 mM $NaHCO_3$, and supplemented with 4.5g/L glucose, 1 mM pyruvate and 15 % fetal bovine serum (FBS, Invitrogen, Basel, Switzerland), penicillin and streptomycin and incubated at 37°C with 5% CO_2. For subsequent seeding, the FBS supplementation was reduced to 10 %. After 12 days, cells were subplated by trypsinisation onto poly-D-lysine precoated 384-well plates at a density of 20.000 cells per well in culture buffer.

Ca^{2+} mobilization assay using rat cortical astrocytes:

After one day of incubation, cells were washed with assay buffer containing: 142 mM NaCl, 6 mM KCl, 1 mM Mg_2SO_4, 1 mM $CaCl_2$, 20 mM HEPES, 1 g/L glucose, 0.125 mM sulfinpyrazone, pH 7.4. After 60 min of loading with 4 μM Fluo-4 (TefLabs, Austin, TX), the cells were washed three times with 50 μl of PBS Buffer and resuspended in 45 μl of assay Buffer. The plates were then transferred to a Fluorometric Imaging Plate Reader (FLIPR, Molecular Devices, Sunnyvale, CA) for the assessment of intracellular calcium flux. After monitoring the baseline fluorescence for 10 s, a solution containing 10μM of representative compound of the present invention diluted in Assay Buffer (15 μl of 4X dilutions) was added to the cell plate in the absence or in the presence of 300 nM of glutamate. Under these experimental conditions, this concentration induces less than 20 % of the maximal response of glutamate and was the concentration used to detect the positive allosteric modulator properties of the compounds from the present invention. The final DMSO concentration in the assay was 0.3 %. In each experiment, fluorescence was then monitored as a function of time for 3 minutes and the data analyzed using Microsoft Excel and GraphPad Prism. Each data point was also measured two times.

The results in Figure 1 represent the effect of 10 μM of Example # 29 on primary cortical mGluR5-expressing cell cultures in the absence or in the presence of 300 nM glutamate. Data are expressed as the percentage of maximal response observed with 30 μM glutamate applied to the cells. Each bar graph is the mean and S.E.M of duplicate data points and is representative of three independent experiments

The results shown in Example A demonstrate that the compounds described in the present invention do not have an effect per se on mGluR5. Instead, when compounds are added together with an mGluR5 agonist such as glutamate, the effect measured is significantly potentiated compared to the effect of the agonist alone at the same concentration. This data indicates that the compounds of the present invention are positive allosteric modulators of mGluR5 receptors in native preparations.

EXAMPLE B

<u>mGluR5 assay on HEK-expressing rat mGluR5</u>

Cell culture

Positive functional expression of HEK-293 cells stably expressing rat mGluR5 receptor was determined by measuring intracellular Ca^{2+} changes using a Fluorometric Imaging Plate Reader (FLIPR, Molecular Devices, Sunnyvale, CA) in response to glutamate or selective known mGluR5 agonists and antagonists. Rat mGluR5 RT-PCR products in HEK-293 cells were sequenced and found 100% identical to rat mGluR5 Genbank reference sequence (NM_017012). HEK-293 cells expressing rmGluR5 were maintained in media containing DMEM, dialyzed Fetal Bovine Serum (10 %), Glutamax™ (2 mM), Penicillin (100 units/ml), Streptomycin (100 μg/ml), Geneticin (100 μg/ml) and Hygromycin-B (40 μg/ml) at 37°C/5%CO2.

Fluorescent cell based- Ca^{2+} mobilization assay

After one day of incubation, cells were washed with assay buffer containing: 142 mM NaCl, 6 mM KCl, 1 mM Mg_2SO_4, 1 mM $CaCl_2$, 20 mM HEPES, 1 g/L glucose, 0.125 mM sulfinpyrazone, pH 7.4. After 60 min of loading with 4 uM Fluo-4 (TefLabs, Austin, TX), the cells were washed three times with 50 µl of PBS Buffer and resuspended in 45 µl of assay Buffer. The plates were then transferred to a Fluorometric Imaging Plate Reader (FLIPR, Molecular Devices, Sunnyvale, CA) for the assessment of intracellular calcium flux. After monitoring the baseline fluorescence for 10 seconds, increasing concentrations of representative compound (from 0.01 to 60 µM) of the present invention diluted in Assay Buffer (15 µl of 4X dilutions) was added to the cell. The final DMSO concentration in the assay was 0.3 %. In each experiment, fluorescence was then monitored as a function of time for 3 minutes and the data analyzed using Microsoft Excel and GraphPad Prism. Each data point was also measured two times.
Under these experimental conditions, this HEK-rat mGluR5 cell line is able to directly detect positive allosteric modulators without the need of co-addition of glutamate or mGluR5 agonist. Thus, DFB, CPPHA and CDPPB, published reference positive allosteric modulators that are inactive in rat cortical astrocytes culture in the absence of added glutamate (Liu et al (2006) Eur. J. Pharmacol. 536:262-268; Zhang et al (2005) J. Pharmacol. Exp. Ther. 315:1212-1219) are activating, in this system, rat mGluR5 receptors.

The concentration-response curves of representative compounds of the present invention were generated using the Prism GraphPad software (Graph Pad Inc, San Diego, USA). The curves were fitted to a four-parameter logistic equation:

(Y=Bottom + (Top-Bottom)/(1+10^((LogEC50-X)*Hill Slope)

allowing determination of EC_{50} values.

The Table 1 below represents the mean EC_{50} obtained from at least three independent experiments of selected molecules performed in duplicate.

EXAMPLE C

mGluR5 binding assay

Activity of compounds of the invention was examined following a radioligand binding technique using whole rat brain and tritiated 2-methyl-6-(phenylethynyl)-pyridine ([^{3}H]-MPEP) as a ligand following similar methods than those described in Gasparini et al. (2002) Bioorg. Med. Chem. Lett. 12:407-409 and in Anderson et al. (2002) J. Pharmacol. Exp. Ther. 303 (3) 1044-1051.

Membrane preparation:

Cortices were dissected out from brains of 200-300g Sprague-Dawley rats (Charles River Laboratories, L'Arbresle, France). Tissues were homogenized in 10 volumes (vol/wt) of ice-cold 50 mM Hepes-NaOH (pH 7.4) using a Polytron disrupter (Kinematica AG, Luzern, Switzerland) and centrifuged for 30 min at 40,000 g. (4°C). The supernatant was discarded and the pellet washed twice by resuspension in 10 volumes 50 mM HEPES-NaOH. Membranes were then collected by centrifugation and washed before final resuspension in 10 volumes of 20 mM HEPES-NaOH, pH 7.4. Protein concentration was determined by the Bradford method (Bio-Rad protein assay, Reinach, Switzerland) with bovine serum albumin as standard.

[^{3}H]-MPEP binding experiments:

Membranes were thawed and resuspended in binding buffer containing 20 mM HEPES-NaOH, 3 mM $MgCl_2$, 3 mM $CaCl_2$, 100 mM NaCl, pH 7.4. Competition studies were carried out by incubating for 1h at 4°C: 3 nM [^{3}H]-MPEP (39 Ci/mmol, Tocris, Cookson Ltd, Bristol, U.K.), 50 µg membrane and a concentration range of 0.003 nM- 30 µM of compounds, for a total reaction volume of 300 µl. The non-specific binding was defined using 30 µM MPEP. Reaction was terminated by rapid filtration over glass-fiber filter plates (Unifilter 96-well GF/B filter plates, Perkin-Elmer, Schwerzenbach, Switzerland) using 4 x 400 µl ice cold buffer using cell harvester (Filtermate, Perkin-Elmer, Downers Grove, USA). Radioactivity was determined by liquid scintillation spectrometry using a 96-well plate reader (TopCount, Perkin-Elmer, Downers Grove, USA).

Data analysis:

The inhibition curves were generated using the Prism GraphPad program (Graph Pad Software Inc, San Diego, USA). IC_{50} determinations were made from data obtained from 8 point-concentration response curves using a non linear regression analysis. The mean of IC_{50} obtained from at least three independent experiments of selected molecules performed in duplicate were calculated.

The compounds of this application have IC_{50} values in the range of less than 100 µM. Example # 29 has IC50 value of less than 30 uM.

The results shown in examples A, B and C demonstrate that the compounds described in the present invention are positive allosteric modulators of rat mGluR5 receptors. These compounds are active in native systems and are able to inhibit the binding of the prototype mGluR5 allosteric modulator (^{3}H)-MPEP known to bind remotely from the glutamate binding site into the transmembrane domains of mGluR5 receptors (Malherbe et al (2003) Mol. Pharmacol. 64(4):823-32).

Thus, the positive allosteric modulators provided in the present invention are expected to increase the effectiveness of glutamate or mGluR5 agonists at mGluR5 receptor. Therefore, these positive allosteric modulators are expected to be useful for treatment of various neurological and psychiatric disorders associated with glutamate dysfunction described to be treated herein and others that can be treated by such positive allosteric modulators.

EXAMPLE D

Amphetamine model of schizophrenia
Amphetamine-induced increases in locomotor ambulation are well known and are widely used as a model of the positive symptoms of schizophrenia. This model is based on evidence that amphetamine increases motor behaviors and can induce a psychotic state in humans (Yui et al. (2000) Ann NY Acad Sci 914:1-12). Further, it is well known that amphetamine-induced increases in locomotor activity are blocked by antipsychotics drugs that are effective in the treatment of schizophrenia (Arnt (1995) Eur J Pharmacol 283:55-62). These results demonstrate that locomotor activation induced by amphetamine is a useful model for screening of compounds which may be useful in the treatment of schizophrenia.

Subjects: The present studies were performed in accordance with the animal care and use policies of Addex Pharmaceuticals and the laws and directives of France and the European Union governing the care and use of animals. Male C57BL6/j mice (20-30 g) 7 weeks of age at the time of delivery were group housed in a temperature and humidity controlled facility on a 12 hour light /dark cycle for at least 7 days before use. Mice had access to food and water ad libitum except during locomotor activity experiments.

Assessment of locomotor (ambulatory) activity: The effects of compounds on amphetamine-induced locomotor activation in mice were tested. Locomotor activity of mice was tested in white plastic boxes 35 cm X 35 cm square with walls 40 cm in height. Locomotor activity (ambulations) was monitored by a videotracking system (VideoTrack, Viewpoint, Champagne au Mont d'Or, France) that recorded the ambulatory movements of mice. Mice were naïve to the apparatus prior to testing. On the test day, the test compound (10, 30 & 50 mg/kg i.p. (intraperitoneal)) or vehicle was administered 30 minutes before the amphetamine sulphate (3.0 mg/kg s.c.). Mice were placed into the locomotor boxes immediately after the amphetamine injection and their locomotor activity, defined as the distance traveled in centimeters (cm), was measured for 60 minutes.

Compound administration: The test compound was dissolved in a 5% DMSO/20% Tween 80/75% saline vehicle and administered in a volume of 10 ml/kg. Compound-vehicle-treated mice received the equivalent volume of vehicle solution i.p. in the

absence of added compound. D-amphetamine sulfate (Amino AG, Neuenhof, Switzerland) was dissolved in saline and administered at a dose of 3.0 mg/kg s.c. in a volume of 10 ml/kg. D-amphetamine-vehicle-treated mice received an equivalent volume of saline vehicle injected s.c.

Statistical analyses: Statistical analyses were performed using GraphPad PRISM statistical software (GraphPad, San Diego, CA, USA). Data were analyzed using one-way analysis of variance (ANOVA) followed by post-hoc Bonferroni-corrected multiple comparisons, where appropriate. The significance level was set at $p<0.05$.

Effect of compounds on amphetamine-induced locomotor activity in mice
Data from such an experiment using a representative compound is shown in Figure 2.

Figure 2 shows that the representative compound of the invention at a dose of 30 mg/kg ip significantly attenuated the increase in locomotor activity induced by amphetamine ($p < 0.01$, $f = 5.385$, $df = (3, 28)$, $n = 8$ per group). Post hoc comparisons revealed a significant effect of the test compound at a dose of 50 mg/kg ($p < 0.05$)
