Field of the invention

15 [0002] The present disclosure relates to a compound represented by formula (I-B), an optical isomer thereof and a pharmaceutically acceptable salt thereof, and a use of the compound as a KRAS inhibitor.

Background

[0003] Cancer has been ranked first among the top ten causes of death in China for 31 years, wherein
20 lung cancer is one of the tumors with the highest incidence, and its non-small cell lung cancer accounts for more than 80%, at the same time, the incidence of lung cancer is high and there are many kinds of mutations. In order to enrich the company's R&D pipeline and focus on unmet medical needs, it is necessary for the company's long-term development to develop innovative drugs for cancer treatment, which has important economic and social significance.

25 [0004] About 30% of cancer patients have RAS gene mutations. In the research of cancer genes, scientists found more than 20 years ago that RAS gene is the key gene of cancers such as lung cancer, colorectal cancer and pancreatic cancer.

[0005] In the United States, the three cancers with the highest mortality rate (pancreatic cancer, colorectal cancer and lung cancer) happen to be the three cancers with the most common RAS mutations,
30 accounting for 95%, 52% and 31% of the patients of these three cancers respectively. In pancreatic cancer, colorectal cancer and lung cancer, KRAS mutation accounts for the absolute majority, while NRAS mutation is more common in melanoma and acute myeloid leukemia, and HRAS mutation is more common in bladder cancer and head and neck cancer.

[0006] The mutation rate of KRAS gene in Asian population is 10-15%, KRAS is one of the major
35 oncogenes, which can mutate in many cancers. KRAS mutant tumor is the most potential targeted molecular subtype of non-small cell lung cancer (NSCLC), and its mutation rate is about 15%-25% in non-small cell lung cancer (NSCLC). In NSCLC cases, KRAS mutations mainly occur at codon 12 and codon

13. The most common codon variation accounted for about 39% of the mutant NSCLCs of KRAS, which is the KRAS-G12C mutation.

[0007] In lung adenocarcinoma, the positive probability of KRAS gene accounts for 1/5-1/4, which is second only to the positive mutation probability of EGFR. The lack of targeted inhibitors makes it very difficult for patients with KRAS-positive non-small cell lung cancer both in terms of treatment and prognosis. The NCCN Clinical Practice Guide for Non-small Cell Lung Cancer in 2013 clearly pointed out that before receiving EGFR-TKI treatment, patients with lung cancer must be tested for KRAS gene, and whether to use EGFR-TKI targeted drugs as a clinical treatment measure should be decided according to the test results. If the KRAS gene is mutated, the patient is not recommended for molecularly targeted therapy with EGFR-TKI.

[0008] According to the Thomson Reuters Competitive Intelligence Drug Database (Cortellis For CI), the current number of various drugs directly related to RAS genes/proteins is 162 (data accessed on August 18, 2016), wherein, there are 18 KRAS small molecule drugs, including 10 KRAS GTPase inhibitors, 4 KRAS gene inhibitors, 2 KRAS GTPase modulators and 2 KRAS gene modulators; there is 1 such drug currently under clinical research. In addition, Antroquinonol, the first KRAS inhibitor developed by a Taiwanese company, has entered the Phase II clinical trial of the US FDA, and Selumetinib, an inhibitor developed by AstraZeneca targeting the MEK downstream pathway of KRAS, is also undergoing Phase II clinical trials. KRAS mutation is the most important tumor driver gene. This part of mutation cases accounted for a certain proportion in pancreatic cancer, lung cancer and rectal gastric cancer. At present, there is no specific targeting drug acting on this target. Therefore, the project has important medical research value and clinical application value, and has greater medical value for nation. The molecular mechanism for developing KRAS-G12C small molecule drug has been basically clarified; the molecular structure and pharmacodynamics of the drug have been verified under the existing experimental conditions, and it has the characteristics of high activity and the possibility of becoming a drug.

[0082] Definition and description

[0083] Unless otherwise specified, the following terms and phrases when used herein have the following meanings. A specific term or phrase should not be considered indefinite or unclear in the absence of a particular definition, but should be understood in the ordinary sense. When a trade name appears herein, it is intended to refer to its corresponding commodity or active ingredient thereof.

[0084] The term "pharmaceutically acceptable" is used herein in terms of those compounds, materials, compositions, and/or dosage forms, which are suitable for use in contact with human and animal tissues within the scope of reliable medical judgment, with no excessive toxicity, irritation, allergic reaction or other problems or complications, and is commensurate with a reasonable benefit/risk ratio.

[0085] The term "pharmaceutically acceptable salt" refers to a salt of the compound of the present disclosure that is prepared by reacting the compound having a specific substituent of the present disclosure with a relatively non-toxic acid or base. When the compound of the present disclosure contains a relatively acidic functional group, a base addition salt can be obtained by bringing the neutral form of the compound into contact with a sufficient amount of base in a pure solution or a suitable inert solvent. The pharmaceutically acceptable base addition salt includes a salt of sodium, potassium, calcium, ammonium, organic amine or magnesium, or similar salts. When the compound of the present disclosure contains a relatively basic functional group, an acid addition salt can be obtained by bringing the neutral form of the compound into contact with a sufficient amount of acid in a pure solution or a suitable inert solvent. Examples of the pharmaceutically acceptable acid addition salt include an inorganic acid salt, wherein the inorganic acid includes, for example, hydrochloric acid, hydrobromic acid, nitric acid, carbonic acid, bicarbonate, phosphoric acid, monohydrogen phosphate, dihydrogen phosphate, sulfuric acid, hydrogen sulfate, hydroiodic acid, phosphorous acid, and the like; and an organic acid salt, wherein the organic acid includes, for example, acetic acid, propionic acid, isobutyric acid, maleic acid, malonic acid, benzoic acid, succinic acid, suberic acid, fumaric acid, lactic acid, mandelic acid, phthalic acid, benzenesulfonic acid, p-toluenesulfonic acid, citric acid, tartaric acid, and methanesulfonic acid, and the like; and salts of amino acid (such as arginine and the like), and a salt of an organic acid such as glucuronic acid and the like. Certain specific compounds of the present disclosure contain both basic and acidic functional groups, thus can be converted to any base or acid addition salt.

[0086] The pharmaceutically acceptable salt of the present disclosure can be prepared from the parent compound that contains an acidic or basic moiety by conventional chemical method. Generally, such salt can be prepared by reacting the free acid or base form of the compound with a stoichiometric amount of an appropriate base or acid in water or an organic solvent or a mixture thereof.

5 [0087] A short horizontal ("-") that is not between two letters or symbols refers to the site where the substituent is attached. For example, C₁₋₆ alkylcarbonyl- refers to C₁₋₆ alkyl which is connected to the rest of the molecule through carbonyl. However, when the attachment site of a substituent is obvious to those skilled in the art, for example, a halogen substituent, "-" may be omitted.

10 [0088] When the valence bond of a group is marked with a dashed line "—", for example in "", the wavy line indicates the point of attachment of the group to the rest of the molecule.

[0089] The compounds of the present disclosure may exist in specific geometric or stereoisomer or optical isomer forms. The present disclosure contemplates all such compounds, including cis and trans isomers, (-)- and (+)-enantiomers, (R)- and (S)-enantiomers, diastereomers isomers, (D)-isomers, (L)-isomers, and racemic mixture and other mixtures thereof, such as enantiomeric or diastereomeric enriched mixtures, all of which are within the scope of the present disclosure. Additional asymmetric carbon atoms may be present in substituents such as alkyl. All these isomers and their mixtures are included within the scope of the present disclosure.

[0090] Unless otherwise specified, the term "enantiomer" or "optical isomer" refers to stereoisomers that are mirror images of each other.

20 [0091] Unless otherwise specified, the term "*cis-trans* isomer" or "geometric isomer" is caused by the inability to rotate freely of double bonds or single bonds of ring-forming carbon atoms.

[0092] Unless otherwise specified, the term "diastereomer" refers to stereoisomers in which the molecules have two or more chiral centers and the relationship between the molecules is not mirror images.

25 [0093] Unless otherwise specified, the absolute configuration of a stereocenter is indicated by a wedge-shaped solid line bond () and a wedge-shaped dashed line bond ().

[0094] The compounds of the present disclosure may exist in specific. Unless otherwise specified, the term "tautomer" or "tautomeric form" means that at room temperature, the isomers of different functional groups are in dynamic equilibrium and can be transformed into each other quickly. If tautomers possibly exist (such as in solution), the chemical equilibrium of tautomers can be reached. For example, proton tautomer (also called prototropic tautomer) includes interconversion through proton migration, such as keto-enol isomerization and imine-enamine isomerization. Valence tautomer includes some recombination of bonding electrons for mutual transformation. A specific example of keto-enol tautomerization is the tautomerism between two tautomers of pentane-2,4-dione and 4-hydroxypent-3-en-2-one.

35 [0095] The compound of the present disclosure may contain an unnatural proportion of atomic isotope at one or more than one atom(s) that constitute the compound. For example, the compound can be radiolabeled with a radioactive isotope, such as tritium (³H), iodine-125 (¹²⁵I) or C-14 (¹⁴C). For another example, deuterated drugs can be formed by replacing hydrogen with heavy hydrogen, the bond formed by deuterium and carbon is stronger than that of ordinary hydrogen and carbon, compared with non-deuterated drugs, deuterated drugs have the advantages of reduced toxicity and side effects, increased drug stability, enhanced efficacy, extended biological half-life of drugs, etc. All isotopic variations of the compound of the present disclosure, whether radioactive or not, are encompassed within the scope of the present disclosure. The term "optional" or "optionally" means that the subsequent event or condition may occur but is not requisite, the term includes the instance in which the event or condition occurs and the instance in which the event or condition does not occur.

[0096] Stereochemical definitions and conventions may be followed in S. P. Parker, editor, McGraw-Hill Dictionary of Chemical Terms (1984) McGraw-Hill Book Company, New York; and Eliel, E. and Wilen, S., "Stereochemistry of Organic Compounds", John Wiley & Sons, Inc., New York, 1994. Many organic compounds exist in optically active form, i.e., they have the ability to rotate planes of plane-polarized light.

- 5 When describing optically active compounds, the prefixes D and L or R and S are used to indicate the absolute configuration of the molecule with respect to its chiral center. The prefixes d and l or (+) and (-) are used to indicate the sign of the compound rotating plane-polarized light, wherein (-) or l indicates that the compound is levorotatory. Compounds prefixed with (+) or d are dextrorotatory. For a given chemical structure, these stereoisomers are identical except that they are mirror images of each other.
- 10 Specific stereoisomers may also be referred to as enantiomers, the mixtures of such isomers are often referred to as enantiomeric mixtures. A 50:50 mixture of enantiomers is known as a racemic mixture or racemate, which can occur in chemical reactions or methods where there is no stereoselectivity or stereospecificity. The terms "racemic mixture" and "racemate" refer to an equimolar mixture of two enantiomers which have no optical activity.

- 15 [0097] The racemic mixture may be used in its own form or separated into individual isomers. Through resolution, a stereochemically pure compound or a mixture enriched with one or more isomers can be obtained. Methods for separating isomers are well known (see Arlinger N.L. and Eliel E.L., "Topics in Stereochemistry", Vol. 6, Wiley Interscience, 1971), including physical methods, such as chromatography using chiral adsorbents. Single isomers in chiral form can be prepared from chiral precursors. Or, a
- 20 single isomer can be obtained by chemical separation from the mixture by forming diastereomer salts with chiral acids (such as single enantiomers of 10- camphor sulfonic acid, camphor acid, α -bromocamphor acid, tartaric acid, diacetyl tartaric acid, malic acid, pyrrolidone-5-carboxylic acid, etc.), and the salt is crystallized in stages, and then one or two of the resolved bases are separated, and this process is optionally repeated; thereby obtaining one or two isomers which do not substantially contain another isomer, i.e., the
- 25 desired stereoisomer with an optical purity of, for example, at least 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99% or 99.5% by weight. Or, as well known to those skilled in the art, the racemate can be covalently linked to a chiral compound (auxiliary) to obtain diastereomers.

- [0098] The term "substituted" means one or more than one hydrogen atom(s) on a specific atom are substituted with a substituent, including deuterium and hydrogen variables, as long as the valence of the
- 30 specific atom is normal and the substituted compound is stable. When the substituent is an oxygen (i.e., =O), it means two hydrogen atoms are substituted. Positions on an aromatic ring cannot be substituted with an oxygen. The term "optionally substituted" means an atom can be substituted with a substituent or not, unless otherwise specified, the type and number of the substituent may be arbitrary as long as being chemically achievable.

- 35 [0099] When any variable (such as R) occurs in the constitution or structure of the compound more than once, the definition of the variable at each occurrence is independent. Thus, for example, if a group is substituted with 0-2 R, the group can be optionally substituted with up to two R, wherein the definition of R at each occurrence is independent. Moreover, a combination of the substituent and/or the variant thereof is allowed only when the combination results in a stable compound.

- 40 [0100] When one of the variables is selected from a single bond, it means that the two groups connected

are directly connected. For example, when L_3 represents a single bond in , it means that the

structure is actually .

[0101] When the listed substituents do not indicate which atom is connected to the substituted group, the substituents can be attached to any atom. For example, pyridyl as a substituent can be connected to the substituted group by any carbon atom on the pyridine ring.

[0102] When the enumerative linking group does not indicate the direction for linking, the direction for

5 linking is arbitrary, for example, the linking group L contained in  is , then  can be linked to the benzene ring and cyclohexane to form  in the direction same

as left-to-right reading order, and can be linked to the benzene ring and cyclohexane to form  in the direction contrary to left-to-right reading order. A combination of the linking groups, substituents and/or variables thereof is allowed only when such combination can result in a stable compound.

10 [0103] Unless otherwise specified, the number of atoms on a ring is usually defined as the number of elements of the ring, e.g., a "5-7 element ring" is a "ring" having 5-7 atoms in a surrounded arrangement.

[0104] Unless otherwise specified, the term "C₁₋₆ alkyl" refers to a linear or branched saturated hydrocarbon group containing 1 to 6 carbon atoms. Examples of C₁₋₃ alkyl include but are not limited to methyl (Me), ethyl (Et), propyl (including *n*-propyl and isopropyl), etc.

[2154] Experimental embodiment 1: Inhibition of RAS-mediated signal transduction

[2155] The ability of the compounds disclosed herein to inhibit RAS-mediated signal transduction was evaluated and demonstrated as follows. Cell NCI-H358(ATCC catalogue number CRL-5807) expressing mutant RAS(G12C) was cultured in RPMI medium containing 10% fetal bovine serum and penicillin/streptomycin double antibody. 40,000 cells per well were spread in a 96-well plate (Corning catalogue number 3699), and the cells were left to stand overnight to adhere to the plate bottom. The cells were treated with or without the compound of the present disclosure (dimethyl sulfoxide, DMSO), and the final concentration of DMSO was guaranteed to be 0.5%. After 2 hours of treatment, the medium was removed and 4% paraformaldehyde (Beyotime catalog number E672002-0100) was added and left to stand for 20 minutes. Cells were washed with PBS after fixation and incubated with precooled methanol for 10 min to permeabilize the cell membrane. 1X blocking buffer (Thermo catalogue number 37520) was added and incubated for 1 hour to block the binding of nonspecific antibody.

[2156] The level of phosphorylated ERK was detected using an enzyme linked immunosorbent assay (ELISA) method. Phosphorylated ERK antibody (Cell Signal Technology catalogue number 4370) was diluted 1: 400 with 1X blocking solution containing 0.05% Tween-20, then the mixture was added to a 96-well plate and incubated overnight at 4°C. The plates were washed 5 times with PBS containing 0.05% Tween 20. The secondary antibody coupled to HRP (Thermo catalogue number 31460) was diluted 1:10,000 with 1X blocking solution containing 0.05% Tween 20, the mixture was added to a 96-well plate and incubated at room temperature for 2 hours. The plate was washed 5 times with PBS containing 0.05% Tween, and TMB (Thermo catalogue number 4816) was added and incubated at room temperature for 15 minutes. The reaction was stopped by adding 1mol/L H₂SO₄, and the OD value was read at 450nm by EnVision (PerkinElmer).

[2157] The total number of cells per well was detected by Janus Green B staining method. After detecting the level of phosphorylated ERK, the 96-well plate was washed with PBS until colorless, and 0.1% Janus Green B (Abcam catalogue number ab111622) was added to incubate for 10 minutes. After the 96-well plate was washed with double distilled water, 0.1 mol/L HCl was added, then the mixture was shaken and incubated for 10 minutes. The OD value was read at 595nm by EnVision (PerkinElmer).

[2158] The signal of pERK (Thr202/Tyr204) was normalized by the signal value of Janus Green B, and the inhibition percentage after drug treatment relative to DMSO reference was calculated. The percentage values were fitted by a four-parameter dose-response curve and generated IC₅₀ values. The experimental results were shown in Table 1.

[2160] The compounds of the present disclosure exhibit excellent ability to inhibit RAS-mediated signal transduction.

[2161] Experimental embodiment 2: Growth ability experiment of inhibition of tumor cell lines expressing KRAS-G12C

5 [2162] The ability of the compounds of the present disclosure to inhibit the growth of cells expressing KRAS-G12C was evaluated by measuring the cell viability and calculating the GI50 values.

[2163] The tumor cell line NCI-H358 (ATCC catalogue number CRL-5807) expressing KRAS-G12C was cultured in RPMI medium supplemented with 10% fetal bovine serum and penicillin/streptomycin, and the tumor cell line MIA PaCa2 (ATCC CRL-1420) expressing KRAS-G12C was cultured in DMEM
10 medium supplemented with 10% fetal bovine serum, 2.5% horse serum, and penicillin/streptomycin.

[2164] Cells NCI-H358 and MIA-Paca2 were inoculated into black transparent bottom 384-well plate (PerkinElmer catalogue number 6007460) with cell density of 1000 and 800 respectively, and the cells were allowed to adhere to the wall overnight (8-12 hours). After the cells adhered to the wall, the experimental group was added with the compound of the present disclosure diluted 5 times the concentration of the working solution (final concentration containing 0.1% dimethyl sulfoxide, i.e. DMSO); the control group
15 was added with the same dilution as the experimental group (final concentration containing 0.1% DMSO). After 72 hours, Cell Titer Glo reagent (Promega catalogue number G7572) was used to detect ATP content according to the instruction method to determine the amount of cell proliferation. The brief operation steps were as follows: the cell plate was taken out and kept at normal temperature for equilibrium for 30
20 minutes; Cell Titer Glo reagent with the same volume as the culture was added; the culture plate was placed on a shaker for shaking and cracking for 2 minutes; the culture plate was left to stand at room temperature for 10 minutes; then the light signal value was read by microplate reader EnVision (PerkinElmer).

[2165] Data from all experimental groups were used to calculate the respective percent inhibition using the DMSO group, and the GI50 was calculated using the data processing software GraphPad to analyze the
25 inhibition rates produced by the 9 compound dose concentrations diluted at 1/3-fold ratio. The experimental results were shown in Table 2.

[2167] **Experimental embodiment 3: Pharmacokinetic experiment:**

[2168] In this experimental embodiment, *in vivo* pharmacokinetic evaluation was performed in mice by intravenous injection and oral administration.

[2169] Experimental methods and conditions: Male ICR mice were given a single dose of 1 mg/Kg (intravenous injection, solvent 5% DMSO+15% Solutol+80% saline) and 5 mg/Kg (intragastric administration, solvent 1% Tween80/2% HPMC/97% water) of the compound to be tested, respectively; 5 min, 15 min, 30 min, 1 hour, 2 hours, 4 hours, 6 hours, 8 hours, 24 hours after administration, blood was collected from the orbital vein, and each sample was collected at approximately 0.20 mL, anticoagulated with sodium heparin, placed on ice after collection, and centrifuged within 1 hour to separate the plasma for measurement. Plasma drug concentration in plasma was detected by liquid chromatography tandem mass spectrometry (LC/MS/MS) to calculate pharmacokinetic parameters. The results are shown in Tables 17 and 18.

[2173] **Experiment embodiment 4 xenograft experiments**

[2174] Nu/Nu Nude female mice (n=7-10) were housed with five animals per cage and given free access to tap water and commercial rat food (Harlan Teklad 22/5 Rodent Feed-8640). Cell line xenograft experiments were performed to make NCI-H358 tumor grow in mice. Once the tumor size reached 300mm³, the animals were randomly divided and treated with vehicle control (1%Tween80+1% HPMC) or compound (the doses were 10 mg/kg/day, 30 mg/kg/day and 100 mg/kg/day, respectively, orally). The tumor volume was calculated using equation) 0.5x length x width x width. At the end of the experiment, the animals were killed, the tumors were collected, weighed, and stored for additional analysis.

[2175] Wherein, the results of body weight changes in mice after the administration of compound 29B were shown in Figure 1, and the results of tumor volume changes were shown in Figure 2.
