

ABSTRACT

METHOD OF REWRITING MESSAGE RECEIVE CONTROL  
INFORMATION STORED IN RADIO PAGER

In order to enable/disable message receipt in a radio pager, a radio transmission is received which is comprised of a pager address code and a message signal which includes a set of control codes. Following this, the pager address code is compared with a predetermined pager ID code. In the event that the pager address code coincides with the pager ID code, the message signal is acquired. Subsequently, it is checked to see if the control code set is present within the message signal. In the event of a positive outcome in the above mentioned checking, the control code set is extracted from the message signal. Then, a piece of message receive control data stored in the pager is rewritten which determines if the message signal is displayed or disregarded.
