CLAIMS

1. A scanning arrangement for a mobile shelving system having a plurality of shelving bays comprising a LIDAR creating a vertical wall of light beams along a side at an outside of the shelving bays, detecting any reflection of the light beams by an obstruction along the side of the shelving bays, determining the location of a break in the vertical wall, and activating the mobile shelving system to move so as to separate shelving bays at that location to create an aisle at that location.
2. The scanning arrangement as in claim 1 where the system does not move until the obstruction has been removed.
3. The scanning arrangement as in claim 1 wherein whilst the shelving system is moving a further obstruction in the light beams causes the shelving system to stop moving.
4. A mobile shelving system including a scanning arrangement as claimed in the above claims.
